

Über dieses Buch

Dies ist ein digitales Exemplar eines Buches, das seit Generationen in den Regalen der Bibliotheken aufbewahrt wurde, bevor es von Google im Rahmen eines Projekts, mit dem die Bücher dieser Welt online verfügbar gemacht werden sollen, sorgfältig gescannt wurde.

Das Buch hat das Urheberrecht überdauert und kann nun öffentlich zugänglich gemacht werden. Ein öffentlich zugängliches Buch ist ein Buch, das niemals Urheberrechten unterlag oder bei dem die Schutzfrist des Urheberrechts abgelaufen ist. Ob ein Buch öffentlich zugänglich ist, kann von Land zu Land unterschiedlich sein. Öffentlich zugängliche Bücher sind unser Tor zur Vergangenheit und stellen ein geschichtliches, kulturelles und wissenschaftliches Vermögen dar, das häufig nur schwierig zu entdecken ist.

Gebrauchsspuren, Anmerkungen und andere Randbemerkungen, die im Originalband enthalten sind, finden sich auch in dieser Datei – eine Erinnerung an die lange Reise, die das Buch vom Verleger zu einer Bibliothek und weiter zu Ihnen hinter sich gebracht hat.

Nutzungsrichtlinien

Google ist stolz, mit Bibliotheken in partnerschaftlicher Zusammenarbeit öffentlich zugängliches Material zu digitalisieren und einer breiten Masse zugänglich zu machen. Öffentlich zugängliche Bücher gehören der Öffentlichkeit, und wir sind nur ihre Hüter. Nichtsdestotrotz ist diese Arbeit kostspielig. Um diese Ressource weiterhin zur Verfügung stellen zu können, haben wir Schritte unternommen, um den Missbrauch durch kommerzielle Parteien zu verhindern. Dazu gehören technische Einschränkungen für automatisierte Abfragen.

Wir bitten Sie um Einhaltung folgender Richtlinien:

- + *Nutzung der Dateien zu nichtkommerziellen Zwecken* Wir haben Google Buchsuche für Endanwender konzipiert und möchten, dass Sie diese Dateien nur für persönliche, nichtkommerzielle Zwecke verwenden.
- + *Keine automatisierten Abfragen* Senden Sie keine automatisierten Abfragen irgendwelcher Art an das Google-System. Wenn Sie Recherchen über maschinelle Übersetzung, optische Zeichenerkennung oder andere Bereiche durchführen, in denen der Zugang zu Text in großen Mengen nützlich ist, wenden Sie sich bitte an uns. Wir fördern die Nutzung des öffentlich zugänglichen Materials für diese Zwecke und können Ihnen unter Umständen helfen.
- + *Beibehaltung von Google-Markenelementen* Das "Wasserzeichen" von Google, das Sie in jeder Datei finden, ist wichtig zur Information über dieses Projekt und hilft den Anwendern weiteres Material über Google Buchsuche zu finden. Bitte entfernen Sie das Wasserzeichen nicht.
- + *Bewegen Sie sich innerhalb der Legalität* Unabhängig von Ihrem Verwendungszweck müssen Sie sich Ihrer Verantwortung bewusst sein, sicherzustellen, dass Ihre Nutzung legal ist. Gehen Sie nicht davon aus, dass ein Buch, das nach unserem Dafürhalten für Nutzer in den USA öffentlich zugänglich ist, auch für Nutzer in anderen Ländern öffentlich zugänglich ist. Ob ein Buch noch dem Urheberrecht unterliegt, ist von Land zu Land verschieden. Wir können keine Beratung leisten, ob eine bestimmte Nutzung eines bestimmten Buches gesetzlich zulässig ist. Gehen Sie nicht davon aus, dass das Erscheinen eines Buchs in Google Buchsuche bedeutet, dass es in jeder Form und überall auf der Welt verwendet werden kann. Eine Urheberrechtsverletzung kann schwerwiegende Folgen haben.

Über Google Buchsuche

Das Ziel von Google besteht darin, die weltweiten Informationen zu organisieren und allgemein nutzbar und zugänglich zu machen. Google Buchsuche hilft Lesern dabei, die Bücher dieser Welt zu entdecken, und unterstützt Autoren und Verleger dabei, neue Zielgruppen zu erreichen. Den gesamten Buchtext können Sie im Internet unter <http://books.google.com> durchsuchen.

This is a reproduction of a library book that was digitized by Google as part of an ongoing effort to preserve the information in books and make it universally accessible.

No. 1.

Lecture on THE CINEMATOGRAPH AND THE TEACHING OF SURGERY. (a)

By PROF. E. DOYEN, M.D.,
of Paris.

Translation by A. A. Warden, M.D. Glasg. (Clinical
Assistant to Prof. Doyen).

ANIMATED photographs were at first used as an entertainment. Only short scenes were represented, a row of films, 18 metres in length, system Lumière or Edison, at the rate of sixteen pictures a second, lasted exactly one minute. The vibration of the picture, always fatiguing to the eye of the spectator, became intolerable when it was a matter of reproducing complicated subjects. Only in the open-air or in a special studio could good negatives be obtained. I endeavoured several years ago to apply the cinematograph to surgical instruction, but was unable to overcome the difficulties referred to; the films were not sufficiently sensitive for the most powerful lenses then in use, and it was impossible to obtain satisfactory results with the apparatus of those days except in the case of a movement of very short duration. Operations on the dead body could easily have been photographed in the open air, but would have had no scientific interest or value. In all medical schools there is an amphitheatre for operative surgery where the use of instruments and technical details may be demonstrated by the professor at each lecture. The students practice on the dead body the ligature of arteries and the various sutures. It is even possible to imitate the flow of blood by connecting the aorta and the carotid with a raised recipient filled with coloured water. These practical experiments give but a very faint idea of true surgery. An operation on a dead body can never be compared to an amputation on the living subject. With a view, therefore, to supplementing this notoriously defective system of instruction, we must have recourse to the cinematograph and reproduce real operations. With the projections we shall be able to explain to our students the difference which exists between real and operative surgery, which has been rightly termed the "Surgery of the Dead."

If we go on to consider such operations as the removal of the kidney, of the thyroid gland, ovariectomy, hysterectomy, the difference becomes more marked, and operative surgery can only be considered the complement of topographical anatomy. The student will study, for instance, the different layers he must traverse to reach the kidney, its exact position, and the relations of its blood vessels. In thyroidectomy or hysterectomy he will appreciate the relations of the thyroid gland, the great vessels of the neck, and the

laryngeal nerves, the exact position of the ureter, the hypogastric, uterine, and vesical arteries. A certain amount of practice can even be obtained in the surgery of the stomach and of the intestines, and familiarity with the blood supply of these organs, the action of the various clamps, and the arrangement of the sutures. But operative surgery will never confer the gift of operating.

Do our books fill the gap thus left? Certainly not. The most detailed descriptions, the best diagrams or photographs of the various steps of an operation are inadequate. Take, for instance, the clamping of the broad ligaments in vaginal hysterectomy. Surgeons who have not seen my crushing forceps used cannot grasp its simplicity, and photographs of the various steps of the operation can only give them a partial idea. On the other hand, with the cinematograph we can make hundreds of people follow in one minute what a whole lecture could not make clear to a limited number of students. Thus there is accumulating in medicine a mass of more or less useless literature, descriptive and critical, and due appreciation of new methods becomes impossible. Surgeons themselves cannot derive the full benefit of visits to foreign schools, and only fifteen or twenty of those who assist at an important operation can follow with profit the details of the technique. The safety of the patient demands that spectators should be at a certain distance; the hands of the surgeon and his assistants conceal part of the field of operation, and the surgeon himself may be the only one to follow some of the more delicate steps. It is not sufficient to follow the operation, as it were, secondhand; but the author of the technique, the master himself, must be seen at work. The surgeon is judged by his work, and no text-books, however well illustrated, can sufficiently express his personality.

It has been with the object of completing our means of teaching the art of surgery that I have been led to study and employ the cinematograph.

The first operations taken by the cinematograph were a craniectomy and an abdominal hysterectomy. The films thus obtained by M. Clément Maurice with the Lumière apparatus, and by Monsieur Parnaland with his own invention, were sufficiently clear to show the value of the method. The first demonstration of the teaching of surgery by the cinematograph took place at the annual meeting of the British Medical Association in Edinburgh in July, 1898. Three films were shown:—

- (1) The manipulation of my operating table.
- (2) An abdominal hysterectomy.
- (3) A craniectomy.

This first demonstration was conclusive and so satisfied the physicians present that I was asked to give a second the next day.

And yet no one has shown a satisfactory series of films since July, 1898, the date of my first demonstration in Edinburgh, the priority of which has never been disputed. Since the meeting of the British Medical Association in Edinburgh I have added to

(a) Paper and demonstration given before the British Gynaecological Society, December 14th, 1899.

my collection of films, which will be issued in a few months for use in teaching faculties. With each film a full description, clinical and pathological, will be supplied. Surgeons who may wish to use the cinematograph themselves, either in operating or in teaching, are welcome to ask us for any details which may spare them errors and expense. Students abroad may thus follow the technique of the great surgeons of the world, they can compare methods and follow the progress of surgery. The historical value of such a possession can hardly be denied. What do we know of the prowess of Maisonneuve, of Lagenbeck, of Billroth or of Péan, who yet are, it may be said, of our own day? How valuable could we follow now with the cinematograph those marvellously rapid operations without chloroform, on the field of battle or in the operative theatre, and see once more the courage of the patient and the skill of the operator.

The progress of surgery is such that what is good to-day is improved upon to-morrow. Thanks, however, to the cinematograph, future surgeons will be better able to judge of the real progress accomplished.

Finally, and perhaps most unexpectedly, the surgeon himself may greatly benefit by the cinematograph. When I saw for the first time one of my operations reproduced on the screen, I recognised how far I fell short of my ideal. Many details of technique that had seemed satisfactory I now saw to be defective, and the cinematograph has thus enabled me considerably to correct and simplify, and to perfect my operative technique. My first films also show the personal progress that I have been able to make. Our films are so clear that the most delicate manoeuvres, such as the suture of the pelvic peritoneum in abdominal hysterectomy, and the opening of the dura mater in craniectomy, may be followed.

You will notice that each operation is done methodically. The patient, the movements of whose respiration can be followed on the screen, is anaesthetised; there is no suffering, and the loss of blood is trifling. The surgeon is calm; his movements are precise and calculated. When he makes a muscular effort you can see his biceps harden, his face contract, his whole body place itself in the most favourable position. The cinematograph registers the whole scene as it takes place, faithfully, rapidly, and in detail. Each step can thus be studied, analysed, criticised. The surgeon can assist at and calmly study his own operations. He can see in his face the anxiety of the moment. He can see himself superintending the respiration of the patient under the anaesthetic. He can see his whole mind set upon the successful execution of some movement, and almost anticipate the smile of relief that follows its accomplishment. Unnecessary gestures and movements may be noted and avoided. The cinematograph has more than once almost startled me in the resemblance I could not help seeing between myself and my late father, Dr. Octave Doyen.

The hours that I have spent with M. Clement Maurice and my assistants studying my technique with the help of the cinematograph have been of the greatest interest and value.

It is a help to all. The anaesthetist is surprised to see himself nervous and anxious at one moment, calm and attentive at another. The nurses who bring the thermo-cautery or who lift away the tumour removed, may see any clumsy movement and correct it.

There seems further no objection to the presence of non-medical spectators at these demonstrations. Members of ambulance societies are in the habit of going to hospital, attending operations, performing

dressings, and learning the principles of antiseptic surgery. Such persons may thus acquire knowledge which will be useful in the case of accidents before medical aid can be obtained.

The cinematograph could usefully be added to such a course of training, and first aid students might learn from it the duties they might later be called upon themselves to perform. And is it altogether to be regretted now, when all classes of society follow with such keen interest the progress of surgery, that the non-medical public should have other means of getting information than inaccurate descriptions? We hardly think so, and those who have seen operations as shown by the cinematograph admit that the calmness of the surgeon, the precision of his movements, the perfection of the operative technique, tend to diminish rather than increase the unknown horrors of an operation. The public will also learn this fact, that an operation as performed by one surgeon is a vastly different matter from the same operation by a different surgeon. There has been too great a tendency to believe that with the triumphs of anaesthesia and antiseptics, surgery has become all but inoffensive. It is time to protest against this error. The success of an operation depends much more upon the skill of the operator than upon the antiseptic care, which every surgeon ought of course to exercise. The cinematograph, registering the details of an operation with the proper speed and perfect accuracy, will show of what mettle the surgeon is made.

If you wish to publish a new procedure, add to your description several rolls of cinematographic films. Each original procedure can thus be compared with methods already published.

Those of my operations are short, and we have heard it said that the cinematograph "went more quickly than the operation." Turn the instrument yourself and you will see upon how little knowledge this criticism is based. If you turn too slowly the movement of the surgeon and his assistants are manifestly slowed; if you turn too quickly there is a rapidity and haste of movement that at once strikes the eye. The operation is only well reproduced if you turn at the same rate as at the moment of operating. My operations, therefore, last just as long upon the screen as during their actual performance. Most of them are not complete; the toilette of the field of operation, the completion of the sutures offer little interest, and would uselessly add to the difficulty and expense of the photographs. The projection that lasts five minutes appears extremely long. Thanks to the cinematograph, I have been able to defend myself against the reproach that I operated too quickly. Study several of the operations on the screen, and you will see that there is no haste and no useless movement, and that the operation is brief because the technique is simple and precise. Operate simply and you will operate successfully. "The more hurry the less speed," in French *hâtez-vous lentement*.

The progress of surgery during the last few years has been due far more to the improvement of technique than to the observance of the laws of antiseptics. The cinematograph will prove this better than descriptions or photographs. I have devoted myself for many years to the improvement of surgical instruments, to the simplification of hæmostasis and operative technique generally, and the cinematograph will make these methods known and permit colleagues abroad to judge of their value. I shall be sufficiently rewarded if I succeed in proving that operations should be simplified to the greatest possible extent, and every useless manoeuvre, every tedious and lengthy procedure, as far as possible

suppressed. In your hysterectomies, in your pylorectomies, in your craniectomies, adopt my technique, and you will be able to finish in a few minutes operations that by other methods will take you half-an-hour or hours. The loss of blood, which used to be considerable, will be trifling, the shock will be insignificant, the recovery rapid. What can the patient gain from a long operation? It would be judicious to operate slowly if slowness were one of the chief factors of success, whereas the contrary is the case. I have never sacrificed safety to speed. I operate at the same time more simply and more surely, whereas the prolongation of an operation adds to the gravity of the prognosis. Do in an hour a hysterectomy that I would do in ten minutes, and in those fifty minutes you will tax the patient's strength by useless movements that may irreparably compromise the vitality of the tissues. The prolongation of the anaesthesia, the increase of the loss of blood, will further injure your patients, and it is thus that operations of two or three hours duration have such a heavy mortality. "Time is Life."

Lectures with the cinematograph should be given as follows:—

(1) The professor briefly describes the operation, and shows upon the screen projections of the principal instruments to be used.

(2) Each step of the operation is shown in detail by fixed projections either of photographs or drawings.

(3) When the technique is thoroughly understood the operation itself is shown on the cinematograph.

If the professor has films of several cases of the same operation, he demonstrates the technique and the necessary modifications in the different cases.

The students need no longer crowd the operative theatres as more or less unintelligent on-lookers. They will be obliged to follow a preparatory course before they actually assist the surgeon. They will then be able to draw profit from his lectures and from the operations themselves.

The application of the cinematograph may be considered one of the greatest improvements in the teaching of operative surgery, since it will make known throughout the world the best methods and the surest means of saving part of humanity from suffering and from death.

THE HYSSOP:

ITS BOTANICAL HISTORY; ITS SYMPTOMATOLOGY; ITS TOXICOLOGY AND ITS THERAPEUTICS.

By JOHN KNOTT, M.A., M.D.,
CH.B., AND DIP. STAT. MED. (UNIV. DUB.);
M.R.C.P.I.; M.R.I.A.

ABOUT a year ago my attention was specially called to the subject of this paper by reading a short editorial on "A Case of Poisoning by Hyssop" in the pages of the MEDICAL PRESS AND CIRCULAR, which appeared January 15th, 1899. Before that date I knew of the therapeutic application of hyssop only from reading; and I believe, I had never heard or read of a case of poisoning due to its administration. Curiosity then induced me to "make up" the subject, and I collected notes from various sources with a view to possible publication. Other more pressing engagements, however, called away my attention from a topic apparently of minimum interest to the majority; with the natural result that my notes got mislaid. I turned them over a few days ago, in rearranging some papers; and, on glancing over their contents, they appeared to me, even after so long an

interval for the cultivation of second thoughts, to contain a sufficient proportion of mental nutriment to justify my bringing them under the notice of the readers of this journal.

The botanic and therapeutic literature of the modest plant which is (popularly) believed to have marked the zero level of the cerebral barometer of the wisest of men is, as we shall see, an extensive one. The foremost place in this selection I give to one of the most exhaustive and copious of British herbalists, John Parkinson. The first chapter of the vast *Theatrum Botanicum* of this writer is devoted to the study of the Hyssop—in all its varieties and their virtues. Those of my readers who have not an opportunity of consulting this great storehouse of antiquated botanical therapeutics may be glad to have an opportunity of perusing his descriptions.

"Hyssopus. Hysope."

"There are sundry kinds of Hysops, whereof the most are unknown to many: whose descriptions, names, and properties shall follow.

"1. *Hyssopus Vulgaris*, common garden Hysope. The common garden Hysope is so well known to all that have a garden, or that have been in a garden, that I shall but seeme *actum agere* to bestow my time in describing it to be a small bushy plant, that riseth up more than a foot high; with many woody branches, but tender; at the tops whereof are set at certaine distances, sundry small long and narrow greene leaves: at the tops of the stalkes stand blewish purple gaping flowers, in spiked heads one rowe above another: after which follow the seed, which is small and blackish; the roote is somewhat woody with many threddy strings; the whole plant is of a strong sweete sent.

"2 and 3. *Hyssopus foliis nireis*: & *foliis aureis*. White Hysope, and golden or yellow Hysope.

"These two sorts of Hysope are both of the same kinde with the common Hysope, but differre only in the party colouring of the leaves; the white having diverse leaves parted white and greene in the midst, and some all or most part white, and some wholly greene, or with some stripes in the greene; for all these sorts are seene together upon one Plant. The golden or willow sort, hath the uppermost leaves usually wholly yellow in the summer time, parted with greene; the lower leaves often abiding without discolouring.

"4. *Hyssopus foliis cinereis*. Russet Hysope.

"This russet hysope also differeth from the former in no other chiefe matter, than in the colour of the leaves, which are of a grayish or ash colour, which some call Russet; this is likely to be that sort that Bauhinus saith was sent him from England.

"5. *Hyssopus surculis densis*. Double Hysope.

"This Hysope groweth lower, and thicker set with slender and not so woody branches, bending somewhat downwards, and much more thicke set with leaves of a darke greene colour; in the flower and other things it differeth not from the first.

"6. *Hyssopus latifolia*. Broad-leaved Hysope.

"This also differeth not from the first here specified, but in having larger and broader greene leaves, upon more woody stalkes, keeping forme and substance.

"7. *Hyssopus foliis crenatis*. Jagged or dented Hysope.

"This difference of the dented leaves, maketh me to set it downe as another species hereof, as others have done.

"8. *Hyssopus moschata vel de cilissa*. Musk Hysope.

"Gesner in *Hortis Germaniæ* remembreth this Hysope to differre nothing from the ordinary Hysope, but in the sent, which is so gracious and pleasant, that it cometh nearest to the sent of Muske.

"9. *Hyssopus Arabum floribus rubris vel albis*. White or red flowered Hysope.

"The red or white flowered Hysope differ but a little from the garden sort, yet are distinguished from it in that they both doe usually beare red or white flowers, all on one side of the spike, yet continue not constant in that forme, but change into the forme of the ordinary kinde.

"10. *Hyssopus minor sive Hispanica*. Dwarf Spanish Hysope.

"This Spanish kinde is a smaller and lower sort, whose branches rise not so high as the garden Hysope, but bend a little downwards, the leaves also being smaller and thicker, and of a sadder greene colour, and the heads or spikes are also shorter, but the flowers are purple like the garden sort. Lobel calleth this *Hyssopus parva augustis foliis*

"11. *Hyssopus Coronatasive Comosa Clusii*. Tufted Hysope. Tufted Hysope is in leaves, flowers, and manner of growing somewhat like the common or garden kinde, but a little smaller and lower, the leaves being of a paler greene colour, and the top branches spreading a little broader, having shorter spikes of leaves and flowers growing as it were in tufts, which hath caused the name, and noted it for a difference.

"12. *Hyssopus foliis crispis*. Curld Hysope. Curld Hysope hath the leaves curled or crumpled at the edges, that each leaf seemeth to be composed of many; and herein consisteth the chiefest difference.

"13. *Hyssopus montana*. Mountaine wilde Hysope.

"Mountaine or wilde Hysope is very like unto the garden kinde for the manner of growing; but that the leaves which are not so many at a joynt, are somewhat harder and rougher, and a little hairie, and somewhat narrower also, which (as Matthiolus saith) being brought into gardens, and there cherished; will by time put off that roughnesse, and become more mild and gentle, the taste whereof is much more bitter, and nothing so hot or sweete as the common kinde: the flowers and seedes are like the garden sort, both for forme and colour.

"14. *Hyssopus angusti folia spicata*. Narrow leafed Hysope.

"Narrow leafed Hysope is a fine kinde, and hath many slender hard stalkes, whereon are set at distances, as in the common Hysope, many small greene leaves, but larger and narrower than they, and ending in a longer point: the flowers likewise grow at several distances, as it were in roundles, almost from the middle of the stalke up to the topes, of a blewish purple colour like the ordinary kinde, but much smaller and so is the seede also: the branches hereof will take roote and grow being laid into the ground, the roote spreading much in the earth.

"15. *Hyssopus foliis origani*. Pound leafed Hysope.

"This Hysope hath divers hard woody stalkes, whereon grow sundry small and almost round leaves, one against another, but pointed at the endes, the heads or spikes of flowers are like unto the common sort, of a blewish purple colour; the sent also differeth little from it.

"Gerard hath set forth an hysope with the leaves of Nummularia. Monyworte, which peradventure might bee this kinde, yet I never saw such an one with him.

"The Place—Pena saith that one common Hysope groweth on the hills of Romania about Verona, and neere unto Mount Raldus; the dwarfe kinde in Spaine, and the mountaine wilde kind, on the hills in many places of Germany, and as Matthiolus saith, on the hill Salvatin in the country of Goritia; the rest, with these also when they may be gotten, are noursed up in the gardens of the curious.

"The Time.—They doe all flower in the summer months of Iune and July, and their seede is ripe in the beginning or middle of August.

"The Names.—It is called in Greeke, *ὑσσωπος*, sic dici putant quasi *ὕμενον* (pro *χρυσομένον*) *ἐπιτον ὠρα* quia super vultus affunditur; in Latine *Hyssopus* & *Hyssopum*; of the Arabians, *Cyfe*, *Iufa*, and *Iaves*; of the Italians and Spaniards, *Hissopo*; of the French, *Hissope*; of the Germans, *Isop*; of the Dutch, *Japen*; and of us, *Hysope*. The names of every one of them are sufficiently expressed in the titles and descriptions of them. But there is a great controversie among our later writers, what hearbe should be the true Hysope of Dioscorides, and other the Greeke authors: for that our common Hysope is not it, but is the true Hysope of the Arabians, as all doe acknowledge except Matthiolus, who doth earnestly contend that our garden Hysope is the same of Dioscorides, whose arguments are too weake to perswade any to be of his opinion, for the description of Dioscorides his hysope hath no face or true resemblance with ours, his bearing tufted heads like *Chrysocome* or *Goldilocks*, as he compareth it, and ours in spikes: the leaves also of his are like unto the *Origanum Onitis*, which are somewhat round like *Marjerome*, as you may see heere shortly after, and are not narrow and long, as those of our Hysope are: therefore *Lugdunensis* setteth forth a round leafed Hysope, which he taketh to be the true Hysope of Dioscorides, but neither are the leaves thereof whitish, as those of *Onitis*, nor doe the heads much differ from the common Hysope: Lobel also propoundeth another, that is our pot *Marjerome* to be the right, in that it hath roundish leaves like *Origanum*, and tufted heads of flowers that are spread abroad like it also, this he saith, is the likeliest hearbe, comming nearest unto the true kinde, unlesse as he saith, it may be referred unto an *Origanum*: but *Fabius Columna* confuteth that of Lobel and *Pena*, as well for that the tufted heads, are more like unto wilde *Marjerome*, then unto *Chrysocome*, or garden *Marjerome*, as *Cratervas*, *Serapio*, *Isaack*, *Mesues* and others doe compare them, as also that the leaves of Dioscorides his hysope, are whitish like unto *Origanum Onitis*, which those of Lobels *Marjerome* is not; besides this, that it is a kitchen hearbe, fit for meate and sawce, and so is our ordinary Hysope also, and not a physicke hearbe as Dioscorides maketh his to be: and lastly, that neither Lobel his *Marjerome*, nor yet our Hysope, are equall in the properties unto that of Dioscorides and others, howsoever it is usually received in the steede thereof: thus saith *Fabius Columna*, and therefore by many reasons would perswade us to beleve, that our ordinary *Polium montanum* is the true hysope, as well for that the leaves are white, and the heades of flowers like unto *Origanum* and *Chrysocome*, as he saith, as also for that his vertues and properties by the bitterness thereof, are more effectuell in all the diseases, whereunto *Plinye* applies his Hysope, which are not remembered of Dioscorides; and that although Dioscorides maketh no bitterness in his Hysope, yet *Serapio* doth as he saith: thus much *Columna*. But let me say, seeing he himself saith, that our *Polium* is answerable in all the parts thereof, unto the *Polium* of the ancients I see no good reason why it should be their Hysope also, and therefore I think, we may as well refuse his *Polium*, as he doth Lobels *Marjerome*. Others, also, would make *Gratiola* to be the true Hysope which hath lesse likelihood than any of the former. *Bauhinus* in his *Pinax* would make our ordinary *Rosmary* to be the Hysope of the Hebrewes, taking peradventure his ground from the Scripture, in *Saint Johns Gospell*, the 19. chap. and 29. verse, where the souldiers bound a sponge wet in vinegar to the end of an Hysope stalk, to put it to our Saviour's mouth when he was on the Crosse, in that the ordinary hysope hath not so long a stalke, as might reach up so high: but both the Evangelists, *Matthew* and *Marke* say it

was a reede, and it may be that the Hysope stalke was bound therevnto, for Saint Iohn as an eye witness of what was done, calleth it as before : Now it is not likely that the Iewes had an other Hysope, divers both from the Greekes & Arabians; but rather that their Hysop was the same of the Arabians, being their neere neighbours, and as it should seeme, was so familiar to their country, that it grew on mudde-walles, as the Scripture saith that Solomon spake of it; which I verily thinke Rosemary doth not. But Hysope is often mentioned in the Scripture to be used in the Iewes ceremonies, which was not without material signification; for as Saint Paul saith, all was done among them in types and figures, and to bee rightly understood and well applied, were worthe of much observation and good use. Now although the true Hysope of Dioscorides, and the other Greekes, is not yet certainly knowne, yet assuredly this which is knowne, and generally received, may safely be used in the stead thereof, untill the true Hysope may be knowne.

"The Vertues.—Dioscorides saith, that Hysope boyled with rue and hony, and drunke doth helpe that that are troubled with Coughes, shortnesse of breath, wheesing, and rheumaticke distillations upon the lungs; taken also with Oxytel, it purgeth grosse humours by the stooles, and with hony killeth the wormes in the belly, and taken also with fresh or new figges bruised, helpeth to loosen the belly, but more forcibly, if the roote of the Flower deluce and Cresses (yet some copies instead of Cardamon have Cardamomum, which I never knew put into any purging medicine in our times, and Macer his verse doth intimate cresses thus: *Cardama si jungas his solves fortius alvum*), be added thereunto: it amendeth and cherisheth the native colour of the body, spoyled by the yellow-jaundice, helpeth the dropsie and the spleene, if it be taken with figges and nitre: being boiled with wine, it is good to wash inflammations, it taketh away the blew and blacke spots, and markes that come by strokes, bruises, or falls; being applied with warme water; it is also an excellent medicine for those, that are troubled with the Quinsie, or swelling in the throate, to wash and gargle it, being boyled with Figges; it helpeth the tooth-ach, being boyled in vinegar and gargled therewith; the hot vapours of the decoction, taken by a funnell in at the eares, easeth the inflammations of them, Mesues saith the singing noyse of them; Pliny addeth, that it is an enemy to the stomacke, and provoketh casting being taken with figges; being bruised, and salt, hony, and cumminseeds put to it, it helpeth those that are stung by serpents. Galen is very briefe herein and onely saith, it is hot and dry in the third degree and of thin parts. Matthiolus saith, that our Hysope is of thinn parts, and that it catteth & breaketh tough flegme, it rarifieth or maketh thinn that which is thick or grosse, it openeth that which is stopped, and clenseth that which is corrupt: the oyle thereof being annoynted killeth lice, and taketh away the itching of the head, it helpeth those that have the falling sicknesse, which way soever it be applyed, but more especially being made into pills in this manner. Take of Hysope, Horehound, and Castoreum, of each halfe a dragme, of the roote of Peonye (the male kinde is most proper in this disease) two drammes, of Assafetida one cruple, let them all bee beaten as they should be, made into seven pilles (or more if they be too great) with the juyce of Hysope, and one of the greater, or two small ones, taken every night going to bed is appointed, the best Physitians of our tymes, assuredly doe account it, to be hot and dry in the third degree, and of thinn parts; for being sharpe and a little bitter withall, they apply it effectually, for all cold griefes or diseases of the chest and lungs, helping to expectorate tough

flegme, that stuffeth or oppresseth them, being taken either in a *lohoc* or licking medicine, or in a Syrupe, or any other way, and in a decoction thus; take an handfull of Hysope, two ounces of Figges, and one ounce of Sugar candy, boyle them in a quart of Muscadine, untill halfe a pint be consumed, which being strained, taken morning and evening, availeth much for those that are troubled with an old cough, by causing the tough flegme the more easily to be avoided: it helpeth also to provoke urine being stopped, or that is made by dropes: it helpeth to breake winde, and to cause women's monthly courses, and easeth the sharpe fitts of agues; the greene hearbe being bruised, and a little sugar put thereto, doth quickly heale any greene wound or cut in the hand, or elsewhere being applied thereto."

(To be continued).

Clinical Lecture.

OTORRHEA AND ITS TREATMENT. (a)

By DR. PAUL RAUGE.

It is unnecessary for me to insist upon the great practical importance of the subject of otorrhœa and its treatment, as there is perhaps no symptom with which medical men have more frequently to deal, and no other affection is more apt to defy his skill and prejudice his professional reputation.

The two most salient features of discharges from the ear are their frequency and their tenacity. This double characteristic is however readily explained by a close examination of the conditions governing the development of otorrhœa and its persistence, that is to say, the bacteriological reasons for suppurative of the tympanum, and the anatomical reasons of its persistency for an indefinite period. No rational treatment of a continuous discharge from the middle ear or its accessory cavities is possible without a thorough appreciation of these two points in the ætiology of the affection. Why is this region more than any other exposed to suppuration, and why does this suppuration persist indefinitely when present? The answer to these questions logically involves the rules of both prophylaxis and treatment, for there is no way of preventing otorrhœa unless one knows how it originates, and no possible means of stopping it, if the reason of its duration is not clearly understood.

The middle ear appears at first sight to be admirably protected against pyogenic microbes, were it not that the tympanum is in communication with the outer air by the Eustachian tube. The existence of this canal deprives the tympanum of all the benefits which it otherwise would derive from its isolation.

The danger is the greater, because the canal opens into a particularly unhealthy region, the naso-pharynx, in which all kinds of micro-organisms abound, even under normal conditions. As long as the lumen of the tube remains as narrow as it is normally, so as to prevent the liquids of the pharynx from passing through with the air, when it is opened at each deglutition, in other words, as long as the functions of the apparatus are regular, the middle ear is protected, and the presence of the tube is no more a source of danger than is the well corked opening of a glass bulb for the purity of a culture.

But if, for some reason or other, the impermeability of the tube is defective, so that some of the microbes in the pharynx get a chance to pass through, mischief results. When pus from an otitis media is collected aseptically and examined immediately after incision of the tympanic membrane, it is as a rule found to contain only a single species of microbe (Zaufal, Netter, Moos), which occupies the field alone as long as the cavity is closed. The moment an artificial or spontaneous opening

(a) Translated for the MEDICAL PRESS AND CIRCULAR from *La Semaine Médicale*.

in the membrane occurs or is created secondary infection becomes possible.

As long as the pus formed in the middle ear remains shut up in the cavity, protected from outside contamination by the still intact tympanic membrane, cultures of this pus present the character of purity and homogeneity, to which attention has been called above. But when communication has been established between the primary focus and the exterior, either through spontaneous perforation or a surgical incision, secondary infections follow in rapid succession, saprophytic species mingling with the pathogenic micro-organisms, and the original invaders in many cases disappearing before the advance of fresh hosts. The microbe of old-standing otorrhœa is the staphylococcus pyogenes, which is as frequently met with at this advanced stage, as it is rare at the onset of the affection. The white variety is the most common, but whether white, yellow, or straw-coloured, whether penetrating through the Eustachian tube or the auditory meatus, whether propagated by the air, cultivated in the cerumen, introduced by the fingers of the patient, or originating in a septic dressing, the staphylococcus unquestionably, in old-standing otorrhœa, occupies the same place as the pneumococcus or the streptococcus at the onset of the affection. It appears, therefore, that, though clinical forms of otitis cannot, as Zaufal suggested, be distinguished by the presence of this or that microbe, their successive appearance, at any rate, marks the different stages of the disease.

Now as to the peculiar conditions which cause suppuration, when once established in the middle ear, to persist with a tenacity, unknown in respect of any other natural cavity, the explanation thereof is to be found in the anatomical features of the middle ear and its accessory cavities which are the sole cause of the persistence of otorrhœa.

Three conditions especially contribute to make this region a sheltered nook, in which pyogenic microbes are enabled to increase and carry on their mischief undisturbed, viz., the irregular form of the cavity, the extent of its walls, and the difficulty of gaining access to it. At the extreme end of the narrow passage, formed by the auditory meatus, is the tympanic membrane, and on the other side of this is a larger cavity, the tympanum properly so called. Although the difference in size between this region and the passage leading to it extends to all parts, it is much more marked above than below, the floor being barely a millimetre lower, so that, on entering the tympanum from the auditory meatus, the floor is almost on a level with the latter, whereas the roof suddenly rises at the point of junction between the two cavities, as soon as the tympanic membrane has been passed. The middle ear, therefore, in respect of the auditory meatus, occupies the same position as the dome or steeple in respect of the nave of the church, whence the name of cupola or attic has been given that part of the tympanum which is situated above both the auditory meatus and the tympanic membrane. It is obvious that this high region must necessarily be inaccessible to ordinary methods of exploration, and that it is as impossible to see the roof of the tympanic cavity through the auditory meatus, as it is from the porch of a church to see the dome towering above it at the other end.

The attic representing, as I have stated, the region of the tympanum which reaches above the tympanic membrane, it follows that its external wall is not formed by this membrane, but by a plate of bone, separating it from the auditory canal, the plane of which, slanting downwards and inwards, forms with the membrane an obtuse angle with the apex turned inwards and upwards. This osseous wall is the obstacle which prevents the attic from being seen, and it is this wall that must be demolished, in order to reach the chamber of the auditory ossicles, whether this be done through the auditory canal, or a wider path be opened by incision of the soft parts behind the pinna (Stacke).

The portion of the tympanum, which is not only hidden from view, but inaccessible to therapeutical measures, is of capital importance in the history of otorrhœa. As a matter of fact, this is the place

where the mischief lurks in the majority of cases of inflammation of the tympanum, and in all observations of otorrhœa "caries of the ossicles, suppuration of the attic" are standing headings. The almost invariable association of these two conditions shows that one is the consequence of the other, and that the frequent occurrence of suppuration of the attic, far from being accidental, is the result of the fact that it lodges the two larger ossicles, which are so often affected by caries in suppurating otitis. It is, in fact, in this upper part of the cavity of the tympanum that the joint is situated which unites the head of the malleus to the body of the incus. Being thus concealed in the dome, there is nothing seen of the ossicles below, except their descending processes (the handle of the malleus and the long process of the incus), hanging down like the bell ropes in a steeple.

Although, from a physiological point of view, the tympanum is the really active part and the centre of the middle ear, it does not by any means represent the entire cavity, which is the seat of the pathological phenomena under discussion. As a matter of fact, it constitutes only a comparatively small part of the irregular space hollowed out in the temporal bone, which in addition comprises the antrum and the mastoid cells. From a pathological point of view, this cavity must be considered as a whole, without taking into account the subdivisions which anatomists have seen fit to make, for the various parts of which it is composed communicate freely with each other, and inflammatory lesions are therefore not limited to any particular portion. It may even be truthfully asserted that the tympanum, properly so-called, is of less importance pathologically than its accessory cavities, on account of the large extent of surface presented by the labyrinth of mastoid cells.

At the postero-superior angle of the tympanic cavity is situated the large orifice by which this cavity is continued into the alveoli of the mastoid process. This orifice leads to a slightly ascending canal (the petromastoid or tympano-mastoid canal, or aditus ad antrum), which opens, behind and above, into a large egg-shaped cavity, the axis of which is antero-posterior and forms the continuation of that of the canal. This is the mastoid antrum. Hollowed out in the base of the mastoid process, and separated from the outer surface by the shell, the cells of which surround it on all sides, the antrum is in reality only the largest of these cells, forming a sort of central hall, around which the secondary cavities are arranged, and into which they all open. On section, therefore, this part of the temporal resembles a wasp's nest, though the alveoli do not open toward the outside, but into a central cavity, around which they form a radiating layer, thicker toward the outside, and especially below. This summary description is sufficient to show that, in the mastoid cavities, the conditions are eminently favourable to copious and lasting suppuration; copious because the secreting surface is enormously increased by the innumerable lamellæ forming the partitions in the alveolar tissue; lasting because each and every cell affords a hiding-place for infective agents. The only effective treatment consists in laying siege, as it were, to each separate alveolus.

Modern anatomo-pathological researches, and the more and more numerous operations performed of late on the mastoid process, have completely changed the views formerly prevailing as to the frequency of this association. Instead of regarding secondary mastoiditis as exceptional and merely as a complication of otitis, it is generally admitted nowadays that it is the almost inevitable consequence of every inflammation of the tympanum (Politzer, Tillaux, Duplay, Luc, Lubet-Barbon, and Broca). It is exceptional, however, for otitis media to stop at the aditus, without overstepping the artificial boundary-line drawn for the purpose of anatomical description between two cavities which are continuous, lined with the same mucous membrane, and obviously exposed to the same pathological influences. There is no doubt that the inflammatory process almost invariably begins in the tympanum, and that it may remain limited to this part of the

cavity as long as it is acute and recent; but when it becomes chronic, one may be assured that the entire cavity is affected, and that the inflammation has been propagated, in a more or less latent manner, to the base of the mastoid cells. All operators have therefore arrived at the practical conclusion that a surgical intervention, to be efficacious, must not be limited to opening the tympanum, as Stacke thought might be done, but that it is necessary to continue the path through the bone, along the aditus, as far as the mastoid antrum and cells.

Although there are as many varieties of treatment as there are forms of otorrhoea, the whole matter may be summed up, I think, for practical purposes under four heads, viz.:—

1. There is as yet no otitis, but an affection in the neighbourhood, such as purulent coryza, pharyngitis, adenoid tumours, and hypertrophy of the tonsils, or a constitutional disease, such as measles, scarlatina, typhoid fever, or tuberculosis, renders this complication imminent. Precaution and prevention are then called for, in other words, the treatment should be prophylactic.

2. There is pus in the tympanum, but the membrane is intact, and thus insures isolation of the abscess.

3. The tympanic membrane is perforated, and the door opened for secondary infection; the acute otitis is becoming chronic, and has changed into otorrhoea.

4. The irritating action of the pus has gone beyond the mucosa, the bones being affected, the incus and malleus necrosed, the carious walls contain sequestra, and the lesions, passing along the aditus, have reached the antrum and mastoid cells.

Such are the various conditions which may call for intervention in the course of suppuration of the ear. I shall now discuss them in detail, in connection with the treatment adapted to each.

Prophylaxis against Abscess of the Tympanum—According to Moos, there are four ways in which pyogenic microbes may enter the ear, viz., through the vessels, the petro-squamous fissure, the Eustachian tube, and the auditory meatus. The latter, which, as I have shown, does not become permeable until at a late period when a perforation of the membrane permits the morbid germs to pass, plays no rôle at the initial stage of otitis, as long as the tympanic membrane is intact. With regard to the vascular and osseous entrance gates, they are so theoretical and apparently so rarely brought into play, while at the same time they are so inaccessible to any prophylactic measures, that it is safe to leave them out of the question in a practical discussion.

Thus only remains the Eustachian tube, to the capital importance of which in primary infection of the tympanum I have already called attention. It constitutes for the microbes of the pharynx the high road to the ear, the only one, in fact, which is always free and open. The orifice of the tube being the regular and normal path, so to speak, along which almost all suppurations without exception proceed, it is at the entrance to this canal that watch should be kept, in order to bar the access to it the moment danger threatens. Above all, the medical man should not forget that he is frequently himself the involuntary cause of a microbial invasion of the ear. An inopportune nasal operation, an imprudent catheterisation, or even a simple palpation of the pharynx or the use of the air douche, when the tube happens to be very wide or its orifice somewhat relaxed, may be sufficient to open the gate to the enemy. It is of the greatest importance therefore to exercise every possible care in any operation directly or indirectly involving the region about the opening of the Eustachian tube, and never to touch this dangerous spot without resorting to the most rigorous aseptic precautions.

The cavity of the naso-pharynx being the storehouse from which the infective elements passing through the tube into the tympanum are derived, it is self-evident that the condition of the pharynx must be carefully looked after, in order to protect the ear. Under normal conditions, it is true, the micro-organisms of this region are inoffensive, owing to the bactericidal properties of the mucus secreted as a measure of defence (Wurtz and

Lermoyez); but under the influence of a constitutional disease, such as influenza and eruptive fevers, or a localised lesion, such as tonsillitis, adenitis, and scrofulous rhinitis, the fluids existing in this region assume an infective character with which the natural defences are unable to cope. The organism then requires assistance in order to be able to keep off the enemy, and preservative measures must be resorted to at once. They consist in carrying away by irrigation the secretions of the pharynx and nose, neutralising the danger by antiseptic measures, such as nasal ointments and powders, and the application of antiseptic fluids to the pharynx, or better still, removing the cause entirely by a suitable treatment of the local affections, ablation of any adenoids which may exist, extirpating in whole or in part the hypertrophied tonsils, re-establishing the permeability of the nose by resection or cauterisation of the turbinates. In short, the treatment called for during this period consists in unremitting care in respect of the cleanliness of the pharynx so as to protect the orifices of the Eustachian tubes. Many cases of otitis, perforation of the tympanic membrane, and subsequent deafness would never have occurred, had the medical man protected the ears of his patients before they were affected, and remembered that prevention is the best treatment of otitis.

In my next lecture I shall deal with the treatment of special phases of these affections.

Clinical Records.

WESTMINSTER HOSPITAL.

Anuria—Transfusion of Saline Fluid—Nephrectomy—Death.

Under the care of Dr. MURRELL.

J. G., a married woman, æt. 47, was admitted on November 22nd, 1899, in a semicomatose condition. No history could be obtained from her friends except that she had passed no urine for two days. She was drowsy and stupid, but could be roused to answer questions, although her answers were monosyllabic and not to the point. She presented an alcoholic appearance. The temperature was subnormal, the pulse 60, there was no paralysis of the face or of the extremities. There was some hypertrophy of the left ventricle and a few scattered râles were heard over the bases of both lungs. The pulse was hard, the tension increased, and the vessels thickened. She made one or two ineffectual attempts at vomiting, but there was nothing peculiar in the odour of the breath. There were no convulsions. The pupils were equal, normal in size, and reacted to light. No ophthalmoscopic examination could be made. The trunk and limbs were covered with old indurated eczema, there was no œdema of the legs, but there was a little œdema about the loins. No urine was passed and there was none in the bladder. Much doubt was entertained as to the diagnosis, but it was thought to be a case of toxic uræmia. Two pints of saline fluid were infused by Mr. E. J. Stilwell into the vein of the right arm, and although the pulse improved in quality her general condition remained unchanged and no urine was secreted.

On the following day some tenderness was detected in the right kidney region and the patient was able to indicate this as the seat of pain. It was thought that possibly it might be a case of anuria due to blocking of one or probably both ureters by fragments of renal calculus. Mr. Walter Spencer, who saw her in consultation, advised right nephrectomy with the view of relieving obstructive suppression. Anæsthetic having been administered by Mr. Frank Bond under circumstances of considerable difficulty an incision was made over the region of the right kidney. There was more than an inch of œdematous fat from which a large quantity of serous fluid exuded. The kidney was found to be soft and vascular, and after incising the capsule Mr. Spencer made an aperture in the pelvis, with dressing forceps and finger. There was a free escape of serous fluid mixed with venous blood. The condition of the patient being unsatisfactory no further exploration was attempted.

and the wound was dressed with iodoform, and stuffed with antiseptic gauze. The patient on the following day was brighter; there was less œdema of the loins, and the abdomen, which had previously been tense, was softer. On passing a catheter into the bladder about a drachm of urine was drawn off, mixed with blood. The patient was unable to retain food or stimulants, and died six hours after operation.

At the post-mortem examination it was found that there was much hypertrophy of the left ventricle, and that the right ventricle was dilated and somewhat hypertrophied. The valves were normal, and there was much atheroma of the aorta over the whole length to the bifurcation. The liver weighed 51 ozs., and was nutmeg in character. The kidneys weighed 3½ ozs. each, and were markedly granular in appearance. Microscopically they were typically fibrotic and highly congested.

Transactions of Societies.

BRITISH GYNÆCOLOGICAL SOCIETY.

MEETING HELD DECEMBER 14TH, 1899.

The President, Dr. MACNAUGHTON-JONES, in the Chair.

Dr. E. DOYEN, of Paris, gave a

CINEMATOGRAPHIC DEMONSTRATION OF GYNÆCOLOGICAL OPERATIONS.

Before proceeding to the demonstration itself, he said:—Gentlemen,—Before giving you my ideas on the use of the cinematograph in the teaching of surgery, allow me to express my thanks to the eminent president of the Gynæcological Society, and to all the members, for the great honour they have conferred in electing me an honorary member. I shall never forget that it was in England at last year's meeting of the British Medical Association, that the cinematograph as applied to surgery was first shown. I had a certain dread in showing my English colleagues my first films. I felt that the idea of the application of the cinematograph to the teaching of surgery might appear strange to them, and I feared that they would view it rather as an exhibition without practical interest, or a vain attempt to make use of the ordinary cinematograph otherwise than a recreation.

The hearty welcome that my colleagues gave to the demonstration in Edinburgh, the public congratulation and encouragements given me by Professor McEwen, Prof. Simpson, and Prof. Chiene satisfied me that the members of the British Medical Association approved of the innovation. There is, however, yet more to acknowledge. After the cordial welcome of my colleagues at Edinburgh, after the great honour of being elected LL.D. of the University, it is once more on English soil that I am officially asked for the first time to give a demonstration of my operative technique as shown by the cinematograph. This century, so rich in great discoveries, will be memorable to the physician of the future as the century of bacteriology and of serum-therapeutics. The surgeon will know it as the century of anæsthesia and of antiseptics, that doubly solid basis of present-day surgery. And in the front rank of the pleiad of men who represent the surgery of the nineteenth century will stand for ever the name of the benefactor of humanity, the father of that antiseptic method without which which anæsthesia had been vain. Need I mention by name Lord Lister?

Initiated in the Listerian method in 1882 in Paris by Lucas-Championnière, practising surgery independently in 1885, my first object was to simplify operative technique and to shorten the duration of major operations which, even at that date, gave a heavy mortality. I set myself to apply to abdominal surgery the established principles of the operative surgery of the extremities as practised by the pre-antiseptic surgeons. My efforts were crowned with success. I have largely transformed surgical instrumentation, suppressed the lengthy and objectless steps of each operation, and by simplifying

the technique have shortened their duration. I have thus had the satisfaction of reducing to an almost unhopèd-for extent the death-rate of certain operations. The mortality of abdominal hysterectomy, in which my technique has been widely adopted, has fallen from 30 per cent. to 5 per cent., and the operation is completed in a third to a quarter the time.

Cranioectomy, by the flap operation, is performed in a few minutes. The duration of vaginal hysterectomy, of nephrectomy, of thyroidectomy seldom exceeds five to ten minutes, and, lastly, the use of my clamp forceps has considerably simplified the arrest of hæmorrhage from thick or vascular pedicles, and the technique of operations upon the stomach, the intestine, and more recently the gall-bladder.

This technique, gentlemen, which is the result of years of care and study is often so delicate in its details that the best description fails to make it clear. The most careful drawings or photographs from nature give but a feeble idea of the reality they are meant to convey. The cinematograph alone enables us to reproduce new methods and to show them abroad. Surgery is based first of all on the principles of anæsthesia and of antiseptics, which may be learned by all who bring the necessary patience and zeal to the task. The work of the surgeon is most difficult. Each day brings new operative procedures, more and more delicate, and more and more the idea spreads that in the future the most skilful surgeons, the best hand-workers, as the word means, will alone be worthy of the name. The teaching of operative surgery for such operations as cannot be demonstrated on the dead body has always been much inferior to the teaching of clinical surgery and of surgical pathology. Too few students could follow with profit the details of such operations in the operating theatre. The cinematograph will fill this blank and complete the surgical training we give to the students of the future.

Proceeding then with the demonstration, Dr. Doyen remarked at the outset that as he was addressing surgeons, the demonstration would be more summary and less detailed than if he had been explaining his technique to students. The method followed in showing each operation was by first projecting a certain number of fixed slides showing consecutively the instruments, &c., required, the various steps of the operation one by one, and second, following this up by showing the operation in entirety as recorded by the cinematograph.

I. Fourteen slides showing the steps in an *ovariotomy* and the details in the use of Doyen's lever-clamp forceps:—

Incision and opening of abdomen.	The lever open.
Incision of cyst.	The forceps closed.
Evacuation of cyst.	The lever opened.
Cyst drawn out.	The lever released.
Examination of pedicle.	Clamping effect of forceps.
Pedicle clamped.	Ligature of pedicle.
Crushing forceps applied.	Section with thermo-cautery.

A complete cinematographic representation of an *ovariotomy* was then shown.

II. Twenty-four slides were then shown illustrative of Dr. Doyen's method of *abdominal hysterectomy*:—

Operating-table in Trendelenburg position.	Section to right of cervix.
Instruments required.	Section to left of cervix.
Further instruments required.	Forceps on uterine arteries.
Abdomen opened, forceps in vagina.	Cervix entirely free.
Tumour raised with corkscrew.	Right broad ligament sectioned.
Section of left broad ligament.	A complicated case, adhesions.
Neither ligament cut.	Same case.
Both ligaments cut, in order to reach cervix.	Orifice of vagina, after cervix was cut.
Cervix seen through opened vagina.	Suture of peritoneum begun.
Incision of posterior cul-de-sac.	Suture of peritoneum completed.
Cervix seized by tenaculum.	Peritoneum closed. Simple case.
Cervix drawn up.	Peritoneum closed. Complicated case.

Cinematographic reproductions of three abdominal hysterectomies were then shown.

The first, taken December 8th, 1899, by artificial light. The second, a case of multiple fibroids with adhesions. The third, showing the suture of the peritoneum completed; all therefore showing the same general method of operating applied both to simple and to complicated cases.

III. Thirty-eight fixed slides were then shown illustrating the technique in *Vaginal Hysterectomy*—

Operating table, special leg pieces.	Extraction of uterus.
Instruments required.	Extraction of left appendages.
Further instruments required.	Forceps on left broad ligament.
Drawing of relations of uterus.	Drawing of same step.
Cervix drawn down.	Section of left broad ligament.
Incision posterior cul-de-sac.	Same from photograph.
Scissors opening Douglas' pouch.	Forceps on right broad ligament
Exploration with finger	Section of right broad ligament.
Incision of anterior cul-de-sac.	Toilet of the peritoneum.
Drawing of relations of uterus at this stage.	Forceps left on broad ligaments.
Cervix drawn down.	Left broad ligament clamped.
Isolation of bladder.	Right broad ligament clamped.
Bladder pushed aside with finger.	Ligature
Diagram of this stage.	Toilet of peritoneum with compress.
Right broad ligament clamped.	Aspect of vulva after operation.
Left broad ligament clamped.	Hysterectomy for fibroid.
Anterior median section of cervix.	Extraction of large fibroid.
Opening of anterior peritoneal cul-de-sac.	V-shaped incision.
	Uterus drawn out at vulva.
	Extraction of a cyst above uterus.

Four vaginal hysterectomies were then shown as they had been recorded by the cinematograph, showing the possibility of demonstrating to hundreds what half a dozen could not see so well in an operating theatre. After the gynecological demonstration, Dr. Doyen showed, at the request of the president, a cinematograph of a nephrectomy, and incision of a goitre. In conclusion, Dr. Doyen thanked the members for their courtesy and attention, and begged to assure them of the sympathy of French scientific men for their English brethren and for the English nation. Dr. Doyen's lecture on the subject will be found at page 1.

Dr. C. H. F. ROUTH, who spoke in French, said:—Monsieur le Président et mes confrères,—C'est un privilège qui m'a été conféré de présenter nos remerciements bien sincères et bien mérités à l'illustre professeur, M. Doyen, qui est venu vous voir de la France pour nous charmer avec une lecture illustrée par le cinématograph sur les opérations gynécologiques, pratiquées par lui-même à Paris et autre part. De faire cette traversée à cette saison, n'est pas très agréable en hiver, surtout lorsque le temps est aussi orageux qu'il l'a été dernièrement. Mais l'amour de la science l'a inspiré à faire ce voyage, et ce soir nous avons eu un très grand plaisir, une instruction parfaite, que nous n'oublierons jamais. Une instruction nouvelle, et qui, avec la lanterne magique, nous a permis de voir toutes ces opérations comme si nous avions les personnes elles-mêmes devant nous. C'est donc un très grand privilège d'avoir non seulement entendu cette superbe lecture, mais de voir M. Doyen opérer devant nous, et suivre par la photographie chaque mouvement de ces mains agissant avec tant d'aise et si exactement. En plus vous savez tous que M. Doyen est un opérateur très distingué parmi même tous les maîtres de la gynécologie chirurgicale. A Paris il est reconnu comme chef dans son art, mais le nom de Doyen est connu partout aussi. La France entière lui fait honneur dans les premières places. Allez où vous voulez, en Angleterre, en Amérique, en Allemagne, en Russie, en Asie, aux Indes, en Afrique, même dans les parties du monde les plus éloignées, comme l'Australie, il est connu, honoré, et apprécié. C'est un citoyen du monde tout entier, et un des plus fameux chirurgiens. Ce que j'ai remarqué dans ces illustrations, c'était la rapidité avec laquelle M. Doyen paraissait opérer. Ensuite chaque instrument préparé, arrivé au moment exact, point de retard, tout à temps, et succès complet de l'opération. Son aide-de-camp à son côté préparé à assister, la nurse à sa place toujours juste; et le chloroformiste marquant chaque mouvement de la malade avec exactitude; on pouvait partout voir que tout était arrangé en ligne, en un mot que M. Doyen était un parfait opérateur. Nous avons, donc, bien raison de remercier, M. Doyen à tout cœur. Nous éprouvons un sentiment de gratitude parceque nous avons entendu une lecture des plus charmantes, et qui nous a enseigné beaucoup. Un autre sentiment c'est celui d'admiration d'un chirurgien si célèbre. Au nom donc de notre distingué Président, et de celui de chacun parmi nous, nous désirons publiquement le remercier avec le plus grand empressement

de reconnaissance et de ravissement satisfait qu'il nous a fait grand honneur en venant parmi nous, et que nous avons écouté et apprécié sa lecture avec le plus grand plaisir.

Mr. SPANTON, in seconding the vote of thanks to Dr. Doyen, observed that one of the pleasantest features of scientific life is the welcome accorded to foreign scientists; and on this occasion the society might deem itself fortunate in having so distinguished a surgeon as Dr. Doyen among them. The exceedingly beautiful and brilliant cinematographical representations had been so well described by Dr. Doyen that it was quite easy to follow every step in the various operations shown; but he thought they ought to bear in mind that an operation so shown and described by one surgeon may be a very very different matter to the same operation performed by another surgeon. Dr. Doyen had initiated a new mode of demonstration which had a great future before it; and Mr. Spanton felt that he was expressing the feeling of all present in saying that the Fellows were greatly indebted to Dr. Doyen for his delightful address, to which everyone had listened with the keenest interest, and in the name of the provincial Fellows more especially, he seconded with the utmost pleasure the vote of thanks so admirably proposed by Dr. Routh.

Dr. GODSON said:—"May I be permitted as a past president to say a few words to express my accord with all that has fallen from the lips of Dr. Routh and Mr. Spanton, and my sense of the deep obligation our society is under to our distinguished Honorary Fellow for having come over from Paris to give us such a pleasing demonstration. To all of us Dr. Doyen has long been known by repute as the king of hysterectomists, and many of us have longed for the opportunity to see him operate. Thanks to the realistic character of the living pictures which he has shown us this evening, I feel sure there is not one of us who will go away this evening without feeling that he has been present at Dr. Doyen's operations, that he can testify to his extraordinary dexterity and skill from what he has himself witnessed, and that he has learnt some useful lessons. I am glad of this opportunity of personally thanking Dr. Doyen for his kindness."

THE PRESIDENT, in conveying the vote of thanks to Dr. Doyen for his most interesting demonstration, said that those who had seen it must remember that these operative methods had not been quickly achieved, but had been arrived at by a true evolutionary process in the progress of gynecology within the last few years. He pointed this out in the various modifications of operative procedure in abdominal and vaginal hysterectomy in which Dr. Doyen himself had played a considerable part. It was one thing, Dr. Doyen performing the operations as he had demonstrated them, it was another that those who were unacquainted with such procedures should go away and fancy they were as simple as they appeared in his hands. If they tried to put this belief into practical effect they would find themselves in a very awkward position. Dr. Doyen was not only a distinguished gynecologist, but he was also one of the most brilliant of French general surgeons, and the Society was proud of the fact that he had been for some time one of its Fellows. On its behalf he tendered to him the warmest thanks for the brilliant demonstration he had given that evening, and for the trouble and pains he had taken in bringing from so great a distance all the necessary apparatus, as also for the special films which he had prepared to show to the Society.

ROYAL ACADEMY OF MEDICINE IN IRELAND SECTION OF MEDICINE.

MEETING HELD FRIDAY, DECEMBER 15TH, 1899.

The President, Dr. J. W. MOORE, in the Chair.

DR. J. LUMSDEN exhibited a case of "Pseudo-hypertrophic Muscular Dystrophy."

Dr. O'CARROLL read a paper on "The Pulmonary Second-sound," and dealt chiefly with the significance of

accentuation of the second-sound in the pulmonary area.

Dr. LANGFORD SYMES read a paper on "The Examination of Sick Children," which we published in our last week's issue.

In the discussion which followed, Dr. DOYLE said that very often in examining sick children it was necessary to resort to an anæsthetic, as he experienced in a recent case of his of hæmorrhage from the bowel. On making a rectal examination under chloroform he discovered a polypus, which was subsequently removed. One of the first things he would look to was the condition of the mouth and pharynx, and all the openings of the body. The possibility of feigned disease should always be borne in mind.

Dr. O'CARROLL said that, as the previous speaker had hinted, the complaints of children might in many cases be due to the suggestive influence of the parent. Children were also quite as liable to hysteria as adults. He did not consider reflexes of much value in examining children under two or three years of age, as the lateral tract was then ill-developed. He emphasised how important it was for a young practitioner to know the times of temporary and permanent dentition.

The PRESIDENT said that it was necessary to gain the confidence of the child before laying a finger on it. He was, therefore, inclined to criticise the recommendation about undressing the child in an out-patient department.

Dr. SYMES, in reply, alluded to the lack of properly organised teaching in diseases of children, and thought that the subject should no longer be neglected. The frequency of disease, its high mortality, the strangely different diseases which are peculiar to children, and, above all, the advantage of the study as a training ground for senior students, combine to strongly recommend it as a most profitable course for the fifth year.

The Section then adjourned.

LIVERPOOL MEDICAL SOCIETY.

MEETING HELD DECEMBER 21st, 1899.

Dr. MACFIE-CAMPBELL, President, in the Chair.

GRATUITOUS ATTENDANCE OF THE FAMILIES OF RESERVISTS.

The following resolution was moved by Dr. J. MOORE DAWSON, seconded by Dr. J. J. O'HAGAN, and carried.

"Owing to the fact that the present war in South Africa has necessitated the calling out of our reservists and volunteers for active service, many of whom have left behind them wives and families in straitened circumstances, we, the members of the Medical Institution, are willing to give our professional services gratuitously to the said wives and families, provided that the cases are authenticated by some recognised authority, and that our services do not interfere with the relations of such families and their present medical attendant."

Dr. CARTER read a note on "Digestives."

Dr. GRIMSDALE related a case of "Fibroid Tumour of the Uterus," causing ascites. The patient was a frail old woman of 67. She had known of the tumour for years. The menopause occurred at 50. For 12 months or so her abdomen had increased much in size so that she had much difficulty in getting about. The abdomen was tense, skin shining, girth measurement 40 ins. Solid tumour could be felt in the fluid. The diagnosis of uterine tumour was easy. The abdomen was opened, two gallons of straw-coloured fluid released from peritoneum. Hard solid tumour nearly as large as the adult head was removed, its attachment to the uterus was two inches by half an inch. This was sewn up with the continuous suture and abdomen closed. Patient made a good recovery. The points of interest were the advanced age of the patient at which it was necessary to remove a uterine fibroid; the occurrence of a large amount of ascitic fluid with a simple uterine fibroid; the roughened surface of the tumour, which had evidently irritated the peritoneum by friction.

Dr. MACALISTER related two cases of "Chronic Paren-

chymatous Nephritis," with the results of prolonged treatment in the Home for Incurables.

Dr. GEMMELL read a paper on

ECTOPIC PREGNANCY.

Taking as a basis of classification that all cases were primarily tubal, he discussed the changes taking place in the peritoneum, muscle and connective tissue of the tube, following the impregnation of the ovum, noting particularly the change in the abdominal ostrum during the first four weeks, and its patency, up to the eighth week, as predisposing to tubal abortion, rather than to rupture of the tube. The uterine deciduum was described, with the characteristic points distinguishing it from an early uterine abortion. Cases were related, and drawings and lantern slides exhibited of the specimens from several recent cases upon which he had operated, illustrative of the termination of tubal pregnancy (a) by destruction of the fetus, or (b) by rupture, extra and intra-peritoneal. The formation of the tubal mole, its analogy to the uterine molar pregnancy, the lamination of the clot and eccentric position of the ovum were noted, and cases of tubal abortion, partial and complete, related. The destruction of the embryo by hæmato-salpinx and pyo-salpinx was questioned. The great essential of accuracy in diagnosis of these cases was the finding in the blood clot or *debris*, microscopic evidence of gestation—viz., chorionic villi and decidual cells, and the very nature of the process of suppuration and degeneration of blood-clot proves the only trustworthy information. Two of his cases he hesitated to class as tubal pregnancy destroyed in this way, for the reason that whilst the clinical evidence was complete, the microscopical was absent. Extra-peritoneal rupture occurring into the meso-metric tissue was the most favourable termination, limiting the hæmorrhage to a broad ligament hæmatoma, and rarely requiring operation. Of the cases of intra-peritoneal rupture the most interesting was one in which the gestation sac with blood clot and placenta, was found in the abdominal cavity, above the uterus, the fetus extruded from the sac, and undergoing mummification, lying between the sac and the abdominal wall. The left tube was cicatrised and blocked at its middle third, and on microscopic examination, proved to be young fibrous tissue being evidently scar tissue. Dr. Gemmell believed this to have been a tubal gestation which had ruptured and extruded the fetus and membranes as a whole, the sac then forming adhesions to surrounding structures, and becoming abdominal. The variations and in many instances want of symptomatology, were referred to; and the treatment described as expectant and operative, the latter being preferred as being in accordance with surgical principles, and with aseptic methods, was eminently satisfactory. Dr. Gemmell had only operated in these cases by the abdominal route, and in the choice of time for operation preferred to wait for the primary collapse to pass off, or in urgent cases, to use an intra-venous saline injection at the time of operation.

Drs. WILLETT, J. J. O'HAGAN, GRIMSDALE, and BUCHANAN took part in the discussion. Dr. GEMMELL replied.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

MEETING HELD AT OWENS COLLEGE, MANCHESTER, DECEMBER 17TH, 1899.

The President, Dr. DONALD, in the Chair.

SPECIMENS.

Dr. J. E. GEMMELL (Liverpool) showed a fetus and placental sac from a case of abdominal pregnancy. The mass was removed by abdominal section, the patient making a good recovery. Microscopic sections of the Fallopian tube were shown. The rupture had occurred close to the uterine end of the tube, and the placenta had developed mainly in the expanded and everted Fallopian tube.

Dr. J. B. HELLIER showed (1) a uterus with multiple fibroids and double pyosalpinx removed by pan-hysterectomy carried out by the "combined" method. The patient made a good recovery. (2) A case of vesicular disease of the great omentum.

Dr. D. LLOYD ROBERTS showed a cyst of the kidney the size of an adult head. The tumour was successfully removed by abdominal section.

The PRESIDENT (Dr. Donald) then gave a Presidential address, entitled "Minor Gynæcology."

In reviewing the changes which had occurred in the practice of minor gynæcology during the last fifteen years, he dwelt especially on the following four points: (1) The use of pessaries; (2) the use of the uterine sound for diagnosis and treatment; (3) caustics and other irritants in the treatment of cervical catarrh; and (4) the methods adopted in out-patient practice for the management of minor gynæcological ailments. He thought that there was considerable divergence in our practice from that which prevailed widely in the early eighties.

SOCIETY OF ANÆSTHETISTS.

Dr. J. FREDK. W. SILK, President, in the Chair.

IMPROVED METHODS IN ANÆSTHESIA.

At the last meeting of the Society the PRESIDENT read a communication from Mr. Walter Edmunds describing a paper inhaler for use with Junker's apparatus for the administration of chloroform, the object being to use a new paper to every case.

Mr. COPESTAKE (Derby) read a paper on "A New Inhaler for Ether, Chloroform, or Mixture," the face-piece of which was made of celluloid.

Dr. FLUX read a paper on a small contrivance for use in the administration of chloroform. A small metal cylinder was attached at the upper end to the inlet of a ball bellows, the delivery tube of which led directly to a face-piece. The cylinder contained cotton wick, and chloroform was poured on it through the lower open end. The instrument was light, portable and easily managed, and possessed the advantage that both the strength and the amount of the mixture were absolutely under control.

A discussion followed, in which Mr. Rickard Lloyd, Mr. Carter Braine, Mrs. Dickinson Berry, Mr. Edgar Willet, Dr. Dudley Buxton, and the President took part, the consensus of opinion being that the suggested improvements were unreliable and difficult of application.

Mr. MCCARDIE read notes of a case of respiratory and cardiac failure during administration of chloroform to a patient probably of so-called lymphatic diathesis, and Mr. RICKARD LLOYD narrated the facts of a case which was under his care.

The President, Dr. Dudley Buxton, Mr. Carter Braine, and Mr. Grant Morris took part in the discussion which ensued, and Mr. McCardie and Mr. Rickard Lloyd having replied, the President concluded the meeting by announcing that on February 2nd the Society would discuss the sequelæ of ether and other anæsthetics more especially with regard to pulmonary complaints.

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, December 30th, 1899.

At the last meeting of the Free Society of Surgeons, Hr. Reichard reported on

THREE CASES OF PARENCHYMATOUS GASTRIC HÆMORRHAGE,

in which at the autopsy no other disease was found that could clearly explain the origin of the hæmorrhage. The first case was that of a man who for several months had been jaundiced, and who showed all the signs of

chronic closure of the choledochus. Laparotomy was performed, the gall-bladder and bile passages were dilated, but no stones were found. Hr. Lindner, the operator, did a cholecysto-jejunostomy; the operation was simple and did not last long. For five days the patient did well, but on the 6th excessive hæmorrhage took place from the bowel, and again on the two following days, and the patient died on the 8th. The autopsy showed the stomach and the whole of the intestines filled with blood, but no visible source of it was anywhere found. The papilla of the duodenum were embedded in a fibrinous mass that pointed to carcinoma. Although the hæmorrhage was favoured in this case by the jaundice, it was not so in the two others. These were two young women, who were admitted into the Augusta Hospital with symptoms of grave anæmia from hæmorrhage from the stomach. One of them had a typical history of ulcer, and she was transferred to the surgical side for operation. Vomiting of blood took place even whilst the patient was on the table. Laparotomy was performed; the stomach, which was filled with bloody mucus, was opened and palpated, but no source of the bleeding was found. The stomach was tamponaded with sterile gauze, and a tube introduced into the duodenum for feeding purposes. The hæmorrhage did not return, but the patient soon died of the persisting anæmia. On section an old cicatrix was found on the lesser curvature of the stomach, but no ulcer.

The other patient had a similar history, and several times when in hospital had hæmatemesis. Laparotomy was performed, and the stomach opened, blood was found in it, but no visible source of it. Death took place in this case also, and section showed no erosion of vessels.

Hr. Ewald said he had known such cases for a number of years. They were to be distinguished from those in which stasis from cirrhosis of the liver favoured hæmorrhage.

Hr. Rinne related a case of

SPONTANEOUS RECOVERY FROM TRAUMATIC RUPTURE OF THE URETER.

The patient from whom the preparation was removed had a gynæcological operation performed only two years previously, during which the operator had the misfortune to cut a ureter across. He made an attempt to repair the damage by suture. For two days the whole of the urine came away through the bladder; after that a part came through the abdominal wound. When the patient came to him she was suffering from severe sepsis; there was pus in the pelvis and an urinary fistula in the abdominal wound. He first of all drained the purulent collection through the vagina, and soon urine began to come that way, and on measuring it the quantity was found to equal to that coming through the bladder. The abdominal wound closed, but the fistula remained in the vagina. After the patient had recuperated somewhat, an attempt was made to get at the ureter extra-peritoneally, but only the central end could be found; the peripheral end could not be traced. The central end could not be implanted in the bladder. The speaker then decided to extirpate the kidney, but before that could be done collapse came on, and the operation had to be deferred. Gradually the discharge of urine through the bladder became less, and one day it ceased altogether. For three weeks the whole of the urine came through bladder, when the abdominal wound opened again, and

urine escaped from it. This continued for fourteen days, when the urine again came altogether through the bladder, and from that time continued to do so.

The patient from that time showed no symptoms of mischief arising from block of the urinary tract.

In November of this year, she again went into hospital with uræmic symptoms, from which she died. Double-sided renal calculus was found to be the cause. The cut ureter had united spontaneously, and was quite permeable.

Hr. Israel read a paper

EXPERIENCES IN DISEASES OF THE PANCREAS.

He said that although cysts of the pancreas, with the exception of those developing in the tail part, and of those with pedicles, were quite immovable, he had observed one belonging to neither of the above categories, which was as movable as a wandering kidney. A woman in the thirties began with headaches and pains in the stomach, which latter sometimes amounted to colic, with vomiting and increasing weakness. On examining in the dorsal position he found a slightly prominent tender and tense elastic tumour under the left ribs. It was about the size of an orange, and when she lay on the right side it sank to that side and could be felt over its whole circumference. When the stomach was empty it could be felt plainly, when full only a small segment could be distinguished.

Laparotomy was performed. After separation of the gastro-hepatic ligament, he came upon the cyst, which was covered with fibrous and glandular structures. These were ligatured and separated in sections, the tumour exposed and removed. It was then seen that the whole pancreas possessed such liberty of movement that it could be drawn out of the abdominal opening. The contents of the cyst were a slightly turbid fluid that changed sugar and emulsified fat. Recovery was uninterrupted.

In another case a cyst of the pancreas had been mistaken for intermittent hydronephrosis, with attacks of pain at intervals of some weeks, the tumour disappearing after the attacks, which generally lasted six days. Finally the attacks became more frequent, but distinct intervals of freedom still remained, although shortened. There was a tumour behind the stomach, as shown by blowing up of this which moved very freely on respiration.

On laparotomy the tumour was found covered by the gastro-colic ligament, and closely attached to the colon. In separating the attachments the cyst ruptured, and in consequence could not be removed *in toto*, but had to be sutured. The fluid which escaped did not possess the ferment properties of ordinary pancreatic cysts. The fluid continued to escape from the wound for 18 days, when the opening began to close. The case was important as showing that exploratory puncture might not yield a fluid corresponding to what would be expected from such a cyst.

Sometimes exploratory puncture alone, of such a cyst resulted in permanent recovery, as shown in one of his cases. The fine needle passed through both walls of the stomach, and did no harm. This was five years ago, and the man had had no return of trouble. Possibly a calculus of the pancreas had been the cause of illness.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, December 30th, 1899.

A NEW TRAUMATIC SPINAL DISEASE.

At the "Doctoren Collegium" last week, Schlesinger repeated his convictions of having discovered a new disease resembling, as he admits, Marie's "Spondylorhizomelique" but, not exactly coinciding with it. After rehearsing all the diseases and authors on the subject of traumatic affections of the vertebræ, he made a differential diagnosis of his new disease that many of the members could not accept. Becteren's disease, he said, differed from his in having a rheumatic origin, while an infection was to be traced to the primary cause of Strümpel and Marie's cases. In Strümpel's an hereditary tendency with individual disposition could be perceived. Another marked difference in the Strümpel-Marie cases was the progress of the ankylosis from below upwards. He would not press this as a constant in the symptoms of the disease, as he had seen cases progressing in the same order.

In the post-mortem room no difference in the "Wirbelversteifung" can be observed. In all the ligaments of the vertebræ ossified, particularly the ligamentum flava and ligamentum apicum. The articulations of the vertebræ are also changed, but if a fresh specimen before maceration be carefully examined, arthritis deformans can easily be diagnosed. He finally admitted that the principal differences in his cases were to be found in the ætiology, distribution, and course of the disease.

Kümmel's cases of spondylitis traumatica were here brought under notice, which he said differed from his own in having the phenomena of shock, after which came a stage of latency followed by motor and sensory paralysis; yet, grave as these symptoms appear, recovery is frequently recorded, which have led to the conclusion that Kümmel's disease is tuberculous in nature, though immediately excited by an injury. However, from the diversity of symptoms recorded in the cases reported Schlesinger is inclined to believe in several diseases being blended in Kümmel's spondylitis traumatica which are not properly isolated.

It has been suggested, Schlesinger said, that the cases I have reported are some form of traumatic spondylitis tuberculosa, or probably a carcinomatous condition in which there may be some truth as it is possible that an injury where such a predisposition exists may localise the tuberculosis, or induce a neoplastic condition, but before we admit this conclusion we must first discover the tuberculous tendency which does not exist in the cases I have reported; neither does radiography assist us in such a conclusion.

OVARIAN TRANSPLANTATION.

At the Gesellschaft Knauer reported the results of his experiments on guinea pigs in which he had transplanted thirteen ovaries. (a) He found that when the ovale was extirpated and placed in a fold of the mesometrium or between muscle and fascia, the animals made excellent recoveries; (b) that the transplanted ovaries three years later were healthy and active functionally, and several of the cases when impregnated at that late period produced three normal young animals, and

no alteration could be observed by the operation. In eleven of the cases, however, the ovaries healed up perfectly, but were somewhat badly nourished, while the uterus and mammae became atrophied.

GUY'S HOSPITAL.

TWO CASES OF SUPPURATING KIDNEY. FIRST CASE TREATED BY EXCISION. SECOND CASE TREATED BY INCISION AND DRAINAGE.—1st. Mr. ARBUTHNOT LANE operated on a fat woman, æt. 65, who had a large tumour in the right loin, clearly nephritic, and giving a history of a discharge of pus at frequent intervals in the urine. It would appear that the condition was one of pyo-nephrosis, originating in the kinking of the ureter in a very mobile kidney. The sensation given to the finger by the tumour, and the length of time during which it had existed, suggested very considerable destruction of the secreting substance of the kidney. The tumour was exposed by means of a long oblique incision, which extended through the loin forwards and downwards on to the abdomen. On cutting into the tumour there was very little kidney substance to be seen in its wall, and as the quantity of pus contained in it was abundant, it was decided to make an attempt to shell it out from its peritoneal surroundings. This entailed much time and trouble, especially in the removal of that part that extended up beneath the ribs. Stout ligatures were then placed round the pedicle, most of the wound closed and the interval filled up with iodoform gauze. Except for a good deal of chronic bronchitis which necessitated her being placed in sedentary posture in bed immediately after the operation, the convalescence was satisfactory and she has now left the hospital. The second case was that of a woman, æt. 35, who suffered from a tumour in the right loin, also renal in origin, and clearly starting in a movable kidney, whose mobility had followed rapid loss of flesh after a confinement. In her case the chief symptom was pain associated with the intermittent passage of quantities of very foul urine in which there was a variable amount of pus. The sensation given by the tumour to the fingers, together with the comparatively short history of the case and the amount of pain experienced during each attack, suggested that there was a considerable quantity of secreting substance left; this encouraged Mr. Lane to hope that by draining the kidney, which would now be fixed in its normal position by the inflammatory process going on about it, the passage might be restored and the remaining kidney substance saved to the patient's permanent advantage. Events turned out precisely as he had hoped. After cutting down on the kidney the wall was found to be thick and to contain much kidney substance. It was drained, and although an abundant discharge took place for some time, it was rapidly reduced in quantity, and at present a sinus alone remains, almost all the secretion from the kidney passing into the bladder. Mr. Lane said he could not protest too strongly against the custom which has arisen among many surgeons of removing hydro or pyo-nephrotic kidneys indiscriminately without making a determined effort to save them. He had known patients exposed to the risk entailed from the operation, and deprived of a considerable quantity of good secreting

material, which he believed could have been saved by more conservative and skilful methods of treatment. Surgeons are often, he said, too apt to trade on the knowledge that life can be carried on by a fraction only of the secreting substance normally provided, and too readily have recourse to the clumsy method of excision rather than fall back upon the various means that may be adopted for re-establishing a free passage between the pelvis of the kidney and the ureter. He had no doubt that a very large proportion of cases of hydro-nephrosis were consequent upon an abnormal mobility of the kidney, and this should, he thought, be taken into consideration in the treatment of movable kidney, in which there is evidence of obstruction, however slight and however intermittent.

ST. THOMAS'S HOSPITAL.

OPERATION FOR UNUNITED FRACTURE OF THE LEG.—Mr. BATTLE operated on the case of a man, æt. about 60, who had been admitted about three months before for compound fracture of both legs. The right one had become firmly healed, but the left continued ununited, although the wound had closed; the fracture was an oblique one about two inches below the middle of the shaft of the tibia, the fibula having been broken at a higher level. The wound had probably been made by the lower end of the upper fragment which was very sharp, and sloped from without inwards and downwards. There was free mobility of the lower part of the leg on the upper at the seat of fractured tibia, but movement on the outer side was at the level of the upper tibio-fibular joint. The limb was of course shortened. After the leg had been thoroughly cleansed and rendered bloodless an incision was made along the front of the tibia, and another inwards from the middle of this to the posterior edge of the same bone. It was then found that the upper end of the lower fragment had been forced under the muscles of the anterior part of the leg, and had become united to the lower end of the upper fragment of the fibula, the upper end of the lower fragment of the fibula was changed by the deposit of callus round it, but had not become united by bone. In order to reduce the upper end of the lower fragment of the tibia, it was necessary to deepen the incision by the side of the upper fragment, so as to permit of stretching of the muscles this incision was carried through muscle, so as to permit the attachment of tibia to fibula being divided; after this had been done and the muscular tissue with fibrous adhesions had been separated from the fragment to some extent an oblique section was made of the broken ends where they came into contact. Before this was done a piece of the upper end of the fibula required removal with a chain saw, so that it might be opposed to the lower end of the upper fragment. A screw was passed from without inwards through these, placed in contact, and, as one screw held them in position nothing further was put in. The bleeding points, which were not numerous, were secured, and the wound closed with interrupted fish-gut sutures. No drainage tube was used. The limb was afterwards placed in a Nevill's splint. Mr. Battle pointed out that although it was rare nowadays to find an ununited fracture of the leg that required operation, still this showed the usual combination found in a large percentage of ununited fractures, for the fracture had been a compound one in the first

instance, and there had been muscle interposed between the ends.

It is satisfactory to state that a fortnight after operation the patient was doing well, there having been no suppuration or interference with the circulation of the limb.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, JANUARY 3, 1900.

THE PAST CENTURY.

To review the past century from a medical point of view is not an easy matter. We are taken back to the time when those who lived were influenced by the work of the Hunterian School; the brothers who set an example which the best men followed, and when in every department of art and science it was a time to be regarded with reverence and esteem. The influence of a great mind such as that of William Hunter's made itself felt. Truth above all things was the aim of those who were with him. It was not for fame or money that men worked, and it was not on the *vulgus profanum* that they relied for support. We pass from them to the next generation, when the troubles on the Continent were subsiding, and attention was being given to the discoveries of Humphry Davy, Wollaston, Jenner, Thomas Young, Matthew Baillie, and their friends. Pathology became of the greatest interest, and was resorted to for the aid it gave in understanding better the causes of symptoms observed during life. The physics of auscultation were brought over from Paris, and the work of Laennec was regarded with the deepest interest. There was no rush after ephemeral ideas in those days, though there was active contest when opinions differed. To the science of chemistry both medicine and surgery owed much. The separation of the alkaloids, morphia, quinine, and others, supplied the physician with valuable aid; while chloroform gave the surgeon an advantage which he was perhaps slow

in appreciating. Certain instruments by which the eye, the ear, and the throat could be examined, were the outcome of improved knowledge in optical science; and the improvements in the microscope enabled the pathologist to see how many morbid processes commenced, and which, without its help, the naked eye or ordinary lenses could not explain. The patient industry of Bright, the energy of Marshall Hall, the originality of Sir Charles Bell are not yet consigned to the pages of history, for there are some still living who remember them. In these days when biographies are the fashion, it is strange that very few appear of those who have worked as physicians or surgeons during the past century. The life of the traveller, and the actor or the politician will naturally interest the public more than that of the man of science; but this is to be regretted, for it is to science that all our progress is due. It is for the profession to show their appreciation of the men to whom they owe their knowledge, and not let their memories fade away. The public cannot judge of the merits of our best men in matters medical and surgical, and it is for the profession to uphold those who benefit it. There is no doubt but that during the last half century the great principle of antiseptic treatment is the most important addition to the art and science of surgery. In medicine the nature of those fevers which were the cause of serious trouble has been studied to much advantage, so that typhus and typhoid are no longer the cruel scourge of the people, and the principle that prevention is better than cure is now recognised most fully. In Sanitary work great reforms have been effected. The importance of proper drainage, and the supply of pure water is admitted on all sides. This practical work was the outcome of the labours of a few rare observers long before the middle of the Century. It would be well to be careful not to obstruct the progress of knowledge by too much devotion to the past. Let the Twentieth Century be commenced in a spirit of ready reception of the work that truly scientific men are offering, and let not the wild outcomes of investigation attract as they are liable to do from the straight and narrow path of Truth. Let the profession realise the duties it undertakes, and let it follow the example of the courage that our soldiers are exhibiting, while it is careful not to allow misguided enthusiasm to mislead.

THE CINEMATOGRAPH IN THE TEACHING OF OPERATIVE SURGERY.

WE are all familiar with the cinematograph as an instrument of amusement; as an instrument of scientific investigation, also, it has had its triumphs, notably in the analysis of the movements of animals. The practical application of the principle of moving pictures to surgical teaching is, however, a comparatively unexplored province, and to the eminent French surgeon, M. Doyen, is due the credit of originating and carrying out the idea. His first demonstration was in our own country, and will be remembered by all who were present at the Edinburgh meeting

the British Medical Association in 1898. The demonstration was repeated before the Third International Congress of Gynæcology and Obstetrics at Amsterdam in the summer of 1899. At the last meeting of the British Gynæcological Society a few days since, a third demonstration was given, and as the Society hospitably threw open its doors, many members of the medical profession in London had the opportunity of witnessing this most interesting new auxiliary to the teaching of surgery. Hitherto, students and practitioners had three ways of learning how to perform an operation; it could be read up in text-books, it could be practised in the dissecting room, and it could be witnessed in the operating theatre. It is a truism that even the best written description of an operation may be a very unsatisfactory guide to its actual performance; the steps of the process usually require to be seen in order to be properly understood. There are some operations of which a fairly satisfactory idea can be obtained by practice on the cadaver, notably the ligature of arteries, amputations, excisions, &c.; but abdominal operations belong to a different category, since in most cases the performance of the operation on the dead body can teach nothing beyond the incision through the parietes. Therefore for this class of cases the operative surgery class-room is practically useless; and the third way has hitherto proved the only way of learning how to perform them. But those who have diligently followed this course, who have strained on tiptoe trying to catch a glimpse of the operator, over the shoulders of more favoured spectators in front, who have been jammed by less favoured spectators behind, or who have found themselves looking on from the sixth row of a gallery, know full well that this way of learning surgery is better in theory than in practice. Scores of onlookers can see the tumour or the limb borne away in a basin after its removal; about three persons can see the steps of the operation in such a way as will enable them to go away and do the operation themselves, and those three are usually the surgeon's assistants. With the cinematograph it is otherwise; during the progress of the operation the instrument comes under the "most favoured" clause, and is placed in such a position as to get a perfect view of the whole operation, and when its impressions are faithfully reproduced lifesize on a screen, the operation as originally performed can be witnessed by hundreds. *A priori*, then, we might expect the cinematograph to prove a really valuable addition to the equipment of a class for the teaching of practical surgery, especially when dealing with abdominal and gynæcological operations. This is the claim made for it by M. Doyen and those who have seen his admirable demonstrations will grant that his claim is well-founded. We shall not be surprised to see some of the larger medical schools introduce this whilom plaything into their own classrooms, pressing it into the service of sound learning; nor can we doubt that in some cases it will have a less soporific effect on a warm summer's day than the soothing voice of the professor. M. Doyen boldly claims for the cinematograph other uses, to which we

can refer only in hushed whispers. He says that it may be used with advantage to show prospective patients what an operation is really like, in order that it may be shorn of its terrors when their own turn comes; further, and more astonishing still, it will prove most useful in showing this prospective patient the calmness, skill and rapidity with which Mr. So-and-so performs this operation, in contrast by inference with Mr. So-and-so, who is not up to date. But we must not pursue this fascinating train of thought. We have been specially favoured with Doyen's lecture and notes of his latest demonstration; these will be found in our present issue, and will doubtless afford our readers much food for reflection.

THE MODERN SURGERY OF GUNSHOT WOUNDS OF THE ABDOMEN.

AT the present moment when the eyes of the whole nation are turned to the war in South Africa, there is, perhaps, one feature thereof which claims more attention than any other, and that is the casualty list which from time to time is issued by the War Office. That this should be the case is only natural, seeing how largely the heart of the nation is bound up with those now fighting for Queen and country against the rebel Boers. But apart from the matter of sentiment, the same casualty lists have a close interest for the medical profession, inasmuch as this is the first occasion, upon an extended scale, in which the officers of the Army Medical Department have been called upon to deal with the wounds inflicted by modern weapons of warfare. Probably, therefore, when the medical history of this war comes to be written, a great many new facts will be forthcoming, and a good many theories exploded. *Apropos* of the harvest of facts which can be reaped from actual warfare, one example may here be mentioned, namely, the experience gained in the late Hispano-American war in respect to gunshot injuries of the abdomen. An interesting paper upon this subject was read last month before the Southern Surgical and Gynæcological Association at New Orleans, by Dr. Grant, of Louisville, in which the experience of the surgeons gained during the war is reviewed. The lessons which that experience teaches is significant. In the first place, Klemm's analysis of 152 cases shows that in nearly all of those in whom penetrating wounds of the abdomen were established, who did not die of immediate effects, eventually succumbed to exhaustion from sepsis, and later, from suppuration; that is to say, as a rule, the only chance of saving life after penetrating gunshot wounds of the abdomen is to operate, for otherwise the victims will either die of hæmorrhage, peritonitis or sepsis. In further proof of this statement the author points to Parkes' statistics, which show the undoubted advantages of operating early in such cases. A study of Parkes' tables renders manifest such variations in the mortality succeeding complicated and uncomplicated wounds of the various viscera, all

of a fatal character without operation, as to indicate that in uncomplicated wounds in some situations the early operations will save from seventy-five to eighty per cent. of what would otherwise be fatal cases. The necessity, then, and urgency of early interference in gunshot wounds of the abdomen seems to be one of the lessons taught by the Hispano-American war, and the experience is such as to bear significantly upon the treatment of our wounded in South Africa. It has been pointed out that extravasation of the contents of the intestines is not so likely to occur in soldiers suffering from abdominal gunshot wounds, as in civilians, inasmuch as the former have generally been without food for many hours before receiving the injuries, and the intestines are consequently practically empty. But abdominal surgery is of necessity special surgery, requiring special skill, and it is hardly to be supposed that the majority of the officers of the Army Medical Department would feel themselves justified in attempting operative procedures of the kind, however necessary such procedures might happen to be. It is evident, then, that the Government should long ago have made preparations for a contingency of this nature by freely accepting the offers of well-known operating surgeons attached to London and other hospitals, which have been made. The announcement has just appeared that four more surgeons have been appointed to proceed to the Cape; but what are they "among so many" of our troops? At least forty and four would be nearer the mark.

Notes on Current Topics.

The War and the Medical Service.

A CORRESPONDENT of the *Times*, with the signature of "R. A. M. C.," points out that at the present moment practically the entire strength of the Royal Army Medical Corps has left the United Kingdom, thus placing the Government in the position of having no medical officers for the seventh and eighth divisions, now in course of mobilisation, to say nothing of the requirements of the Militia, Volunteers, and Yeomanry proceeding on active service. He also directs attention to two recent acts of the War Office, showing want of tact and opposition to the interests of the service. "Surgeon-General Nash, the late P.M.O., Netley, had to retire under the age clause on November 8th last. He could have been retained on full pay for any period up to two years, and he even offered to remain as P.M.O., Netley, after he was retired, and carry on the duties; but, no, he was turned out and another officer nominated to the charge. At the same time one of the ablest Surgeon-Generals in the service (Surgeon-General Evatt) was sent down to Devonport to take charge of the Western District, from which all the troops have been withdrawn." The correspondent also complains that the War Office have invited the retired officers 'liable to be recalled to service' to return to active duty, which means that instead of resuming their

former status in the service they are called upon to rejoin and serve under officers many years junior to themselves, besides losing their right to promotion and further pension. The Royal Warrant, on the other hand, lays down that such retired officers, in cases of national emergency, can be recalled and the opportunity afforded them of resuming their original places in the army list, and that all full-pay service, while so recalled, would count for further promotion and higher pension. These are only some of the ways which the War Office adopt to render the medical service of the army unpopular. But it is quite likely that the present "clique" at the War Office will find themselves arraigned before the nation after the present hostilities have ceased, both for sins of omission and commission, and then will be the time to show up their animus and spite against the Army Medical Department.

The Influenza Pest.

THIS dreaded disease has not only disappointed all hopes of its disappearance but has returned with greater vehemence than ever. It may be doubted whether any previous outbreak has attacked so many persons as the present, although, happily, the mortality has not been nearly so high as that met with in some of the earlier epidemics. Christmas Day all over the United Kingdom was more or less blighted by the advent of this unwelcome visitor, and in many cases both guests and hosts rose from bed to keep their dinner engagements. The unwisdom of such a proceeding, especially in such inclement weather as that which characterised Christmas Day, cannot be too strongly insisted upon. Yet we doubt if many of the foremost offenders have not been medical men, whose disregard of influenza is not a little remarkable, considering their knowledge of the course of the disease. As everyone should know by this time, a slight attack of influenza is just as dangerous as a sharp one. The average individual is absolutely safe if he stay warm abed, but if he go about his condition is at once shifted from security to danger. These facts have been demonstrated again and again until they are mere household maxims in ordinary medical practice. The infectiousness of the disease was well illustrated by the remark of a chemist, who said that when he got one prescription from a large household he knew that sooner or later he should send physic to every one else in the house, including the servants. There has been a famine of nurses, greater perhaps than has been experienced in any previous outbreak. Another feature has been the number of members of hospital Staffs attacked by the malady, so that many institutions have been for a time almost entirely deprived of the services of their resident and visiting Medical Staffs. In one case the popular surgeon of a London Hospital was married to a lady who actually left the sickroom, where she had been kept by a sharp attack of influenza, to attend the church. What between the "flue" and the war at the Cape, the Christmas season has been anything but festive.

Enteric Fever at the Cape War.

NOT the least of the serious questions that have been raised by events at the Cape with regard to army medical administration is the large number of deaths from enteric fever. In a properly administered army service, even on campaign, the disease should be almost if not quite unknown. It is small excuse to say that sanitation is absent in many or most parts of South Africa away from the large towns. Typhoid fever is preventible, and is practically a water-borne disease. What steps have been taken to keep the infection away from an army invading an admittedly fever-stricken country? Have arrangements been made for guarding the water supply in every detail? Have tubular wells been plentifully distributed, together with means for sterilising stream and well water, and pocket filters of the Pasteur type? Unless these things have been done we should say the Army Medical Department has not adopted reasonable precautions to prevent enteric fever decimating our troops in this South African campaign. It is much to be feared, however, that the spirit of enterprise has been hopelessly dwarfed long ago in the Army Medical Department, whose entire reconstitution, with a full recognition of status and responsibility, is urgently demanded. It is with cholera and enteric fever in India as with enteric fever at the Cape. An Army Medical Department alive to modern scientific methods and allowed a tolerably free hand would, in neither place, have permitted pestilences to stalk, practically unchecked, through the ranks committed to their charge.

The Discovery of Scabies.

ALTHOUGH, as far back as the twelfth century Avenzoar described a disease of the skin characterised by the presence beneath the epidermis of animalcule resembling lice, so small as scarcely to be visible, which, he remarked, could be extracted by scratching the skin, the disease now universally known as scabies was, even as recently as this century, regarded as a constitutional affection associated with cachexia and inflammation. It appears, however, that Rabelais, who, though a doctor of medicine is better known as a political writer than as a physician, was well acquainted with the disease, and was perfectly cognisant of its nature, contagiousness and treatment. It is narrated indeed in his famous work that one of the ancestors of Pantagruel was "exceedingly expert in removing worms from the hands," and elsewhere Rabelais laments the death of a medical friend who died in consequence of his having accidentally wounded himself in removing one of these worms with a paper knife. The rediscovery of itch in France dates from 1835, when a medical student demonstrated to Alibert, incredulous, how in his native land of Corsica the peasants withdrew the parasite by the aid of a needle, a feat which he repeated in Alibert's clinic. In a recent monograph on the subject it is shown that the disease has been discovered and rediscovered some half-dozen times, at intervals of centuries. How often is this the case

with medical discoveries? The worst of it is that treatments which have been again and again discovered and dismissed as useless or injurious are from time to time once more brought forward only to excite and cause fresh disappointment. If contemporary discoverers would only take the trouble to consult Neale's Digest or the "Index Medicus" before launching their fancied innovations, they would often be dissuaded from encumbering medical literature with their "mare's nests."

Humidity and Disease.

THE quantity of water vapour contained in the air varies within very wide limits according to the temperature and the direction of the prevailing winds. It is, however, not so much the absolute quantity of water vapour in the air that exerts an influence on health as the proportion in relation to the saturation point of the air, in other words it is the degree of interference with cutaneous and respiratory evaporation that is of importance. Sudden and extreme variations in the proportion of atmospheric humidity exert a well-marked influence on the absorption, transmission, and reflection of heat, light, and electricity, and these variations affect in a marked degree the activity of the vital processes. According to M. Chiais, the proportion of water vapour has a pathogenic influence whenever it falls below five or six grammes per cubic metre, or rises above twelve to thirteen grammes. If the air contains less than five grammes the tendency is to diseases of the congestive type and the mortality returns are increased by maladies affecting chiefly the respiratory tract though this circumstance acts prejudicially on sufferers from chronic cardiac disease and enhances the tendency to cerebral congestion, apoplexy, &c., in the aged. If, on the other hand, the air contains more than fourteen grammes per cubic metre of water, the tendency is to inflammatory affections of the intestinal tract, gastro-enteritis, and the like. There is reason to believe that it is less the relative abundance of water vapour that tells than the occurrence of sudden variations, these variations placing the organism at a disadvantage, only the physiologically active being able to adapt themselves to the change.

The Bacteriology of Holy Water.

AN unscrupulous Italian bacteriologist recently took the trouble to obtain supplies of holy water from the *benitiers* of sundry churches in Turin and subjected them to bacteriological investigation. As might be imagined, in a country where personal cleanliness is not a very marked feature, he reaped a rich harvest of microbes. He describes the samples as "extraordinarily rich in mobile and immobile bacteria, infusoria and various animal and vegetable organisms." Guinea-pigs inoculated with the centrifugated liquid died, for the most part with symptoms of septicæmia, one, however, dying of tuberculosis. Not to be without a moral, our observer urges that steps should be taken to ensure the periodical cleansing of the recipients, and the passage of

a current of fresh water through them. How he imagines that water, even if rich in infusoria, could possibly prove injurious to the faithful by merely coming into contact with the skin he does not explain.

General Hospital Dentistry.

THE most obvious anomaly in the medico-educational system is the ostentatious neglect of some of the subjects which are manifestly most necessary for the general practitioner. Who ever heard of a candidate at examination being asked to pass a catheter, or to show how a leech should be applied, or to apply a cupping glass or even to put in a hypodermic injection? A practitioner may be sent out into the world without knowing how to adjust a head bandage or splint a broken clavicle, but not unless he is familiar with the latest views on the pathology of some disease (or to detail the symptomatology of exaltative monomania), neither of which he will probably ever see in a life time. This neglect of a speciality is, perhaps, more obvious in the case of dentistry than in that of any other of the requirements of the general practitioner. The first case he meets with is likely to be one of tooth extraction, and his attendance on such cases is measured by scores of hundreds in the course of the year. Where does he learn to operate? In an extern dispensary with a bundle of out-of-date old instruments and without any one to tell him even which tool is wanted for a particular tooth. He is, in his first or second year, let out on the unhappy sufferers from toothache, and is lucky if he manages to extract the offending tooth instead of breaking off its crown or splintering the alveolus. In this way he acquires, before his fifth year comes, some limited experience, while his patients' vile bodies are the only instructors from which he learns. It is always possible, no doubt, for him to pay a high fee and spend much valuable time in attending a special dental hospital, and, if time and money are of no importance, he will derive benefit from doing so, but the drilling out and filling of cavities and the making of plates and sets are not what he wants for general practice, and therefore the great majority of students never seek to be instructed therein. We say nothing of the tortures which the out-patients suffer under this method of instruction in dentistry. That is a negligible detail.

The Death-roll of Aged Persons.

DURING the past week or more the announcement of deaths in the daily newspapers has assumed an unusual proportion, and the most noticeable feature thereof has been the large number of elderly persons who have died. For example, during the first four days of last week the death column of the *Times* recorded the deaths of no fewer than ninety-one persons of upwards of seventy years of age, fifty-three of whom were eighty and upwards, and eleven were over ninety. It is impossible to doubt that the changeable and trying climatic conditions to which we have been subjected of late has had much to do with this death roll. Cold, damp, foggy weather is especially destructive to feeble old persons,

disposed to catarrhal attacks. A few of the octogenarians who have recently died may have succumbed to an attack of influenza, but it is worthy to note that the fatal cases of this disease have, so far, not been numerous during the pre-ent season.

"A Hero of the Red Cross."

IN our contemporary, the *Graphic*, of this week a full page engraving appears of a pathetic scene with the above description. A wounded soldier is lying on a stretcher on the field of battle. On his left hand side is a hospital assistant holding a tray of instruments; the surgeon is on the right of the patient just about to begin an operation. But he has been struck by a bullet, and the engraving shows him to be falling backward over the prostrate form of his patient. The hospital assistant has a look of horror and dismay upon his countenance, and his feelings can be readily imagined under the sad circumstances. The scene vividly depicts the risks to which officers of the Army Medical Staff are exposed during the present war. The Boers have been repeatedly proved to be no respecters of ambulance parties, and consequently the casualty lists of the large engagements already fought have always contained the names of medical officers who have been killed. At all events, at least three officers of the Army Medical Service have been shot dead while attending to their duties on the field of battle during the present war.

Pigeon Messengers.

IN country districts where the telephone is not as yet available, patients often find it very difficult to convey messages to the doctor's house in case of need. A French country doctor, it seems, has for some years past made use of carrier pigeons for the purpose. When he is in charge of a serious case at a distance he leaves one or two pigeons at the house by which means he is enabled periodically to receive information which will enable him to decide whether or not it is necessary to make a subsequent visit on the same or the following day. The trustworthiness and promptitude of these winged messengers appear to have left little to be desired, messages from a distance of seven miles arriving within from one-half to three-quarters of an hour. Pending the generalisation of wireless telegraphy it is possible that assistance may occasionally be derived from this novel method of "ringing up the doctor."

"The Dioptric and Ophthalmometric Review."

THE British Optical Association, whose president is Mr. John Browning, the optician, possesses a journal with the above title. It is, of course, devoted especially to the interests of the trade, and to those members thereof who seek to provide the public with spectacles independently of the ophthalmic surgeon. In a copy, therefore, of the journal in question forwarded to us by a correspondent, we were somewhat surprised to see an article contributed by a member of the profession, Dr. Clements Hailes, of the Bristol Eye Hospital. The subject of the article

is "Tobacco Amblyopia," a subject which we altogether fail to see can have anything to do with the trade of spectacle making. It is not usual for medical men to contribute signed articles to lay publications, and still less so to those which seek to pose as organs of professional opinion. We doubt not that Dr. Hailes has inadvertently fallen into the error of contributing a professional article to a trade publication, and, under these circumstances, it is not necessary to say anything more upon the matter. Perhaps the Ophthalmological Society will enlighten the medical world as to its position in relation to this Society, of which one of the members is, we believe, an examiner.

The Charity Organisation Society and the War.

WHATEVER may be thought of the principles upon which the Charity Organisation Society has been founded there can be no doubt whatever as to the unpopularity of the methods adopted by that body. Their latest feat has been to stir up the anger of the public by staying the hand of relief stretched out to the wives and families of soldiers who are gone to fight our battles at the Cape. Money must not be given to any such person, forsooth, until the Society has satisfied itself that the antecedents of the absent soldier have been without a flaw. The temper of the British public must break forth at once in a blaze of indignant protest against such mean and paltry censoriousness. By freely offering their lives in the present strait our soldiers have more than purged any offences of the order that apparently stinks in the nostrils of this pharisaical Charity Organisation Society. Besides, are innocent women and children to suffer for the past peccadilloes of their soldier fathers? It is to be hoped that no distribution committee will be influenced by any reports received from this officious society, unless it be to increase the grants forthwith of all who are thus singled out as the victims of a misdirected principle. The proceedings of the Charity Organisation Society have long been a rock of offence to the noble spirit of philanthropy that permeates Great Britain. To regulate indiscriminate alms-giving and to check active roguery is one thing, to persecute the poor with harsh severity, as though poverty and past offences were crimes, is another. A Parliamentary inquiry into the work, the revenues, the cost of administration and the achievements, past and present, of the Charity Organisation Society would be a not altogether unadvantageous step.

A Remarkable Escape.

DR. LIVINGSTONE, a district surgeon at Ingwavuna, Zululand, has arrived at Durban, and tells a remarkable story of his escape from a Boer commando which invaded Zululand, and effected his capture. The commando, which numbered 275, took possession of the magistracy, and cut the telegraph wires. The *St. James's Gazette* reports that the officials took to their heels and bolted into the bush, but Dr. Livingstone was caught. He stumbled unexpectedly upon the Boers, who promptly covered him with their

rifles, took his horse, rifle, and ammunition away from him, and marched him off towards Vryheid. Some of the Boers in the commando had been previously medically treated by Dr. Livingstone, and with these the prisoner was on fairly good terms. When the commando encamped for the night four men were mounted guard over Dr. Livingstone, but about midnight the prisoner, who knew almost every inch of the country, quietly rolled up his mackintosh and made a sudden rush for a neighbouring ravine. Before his astonished guards had thoroughly grasped the situation the prisoner had gained a good start; but the whole commando was soon in hot pursuit. In the darkness, however, Dr. Livingstone eluded all his pursuers, and made his way to a Kaffir kraal where he was kindly treated and provided with an escort and scouts. He eventually reached the Ingonia Magistracy in safety, purchased a horse, and made for the Lower Tugela, where he has been congratulated on all hands on his daring escape.

Surgical Millinery Again.

THE cuckoo patiently incubating the hedge-sparrow's egg is not a more interesting spectacle than the austere Council of the Royal College of Surgeons of England engaged in the hatching out of the millinery details of the famous "Member's gown." This garment, we are told, is to be appropriately constructed of "a black stuff (and nonsense)," and it is to have "a plain unlooped sleeve, and the facings are not to extend to the back or be more than two inches in the widest part." We put it to the Members of the College that they are publicly branded with ignominy by being compelled to wear an unlooped sleeve and a beggarly two inch facing, and we doubt not that the great gown riot will be resumed if the Council does not forthwith decree a looped sleeve. "Who dares this pair of boots displace, Must meet Bombastes face to face."

A New Method of Killing the Tænia Solium.

AN American practitioner has discovered a new way of ensuring the death of the tapeworm, viz., by injecting it with a solution of morphia. Obviously it is indispensable for the practicability of this method that the worm should have been unguarded enough to escape in part from the anus. When this is the case all we have to do is to apply a ligature and inject a solution of morphia into the remainder, whereupon the worm, as a whole, dies and is expelled within a short time. So far so good, but the process is perilously like that of putting salt on a bird's tail, and this drawback is likely to militate against general recourse to the method.

The Newest Stimulant.

AN inquest was held recently on the body of a woman resident in the North of Ireland, aged 30. She had driven from a distance on a very cold night, and finding no more agreeable calorifier in her house than some vitriol, took some of it mixed with water

and as she found the effects unpleasant she followed the dose with some laudanum which she happened to have and then incontinently died. Apparently the pharmaceutical schoolmaster is not abroad in the North of Ireland.

THE West London Medico-Chirurgical Society have arranged to devote the February meeting of the Society to a discussion on syphilis, which will be opened by Mr. Alfred Cooper, F.R.C.S. Visitors, introduced by members, will be welcomed by the President and Council, and will be invited to take part in the proceedings.

THE Executive of the Dublin Port and Docks Board has appointed a committee to advise as to the future arrangements for the duties of Medical Officer to the Board vacated by the death of the late Mr. Hamilton. It is scarcely needful to observe that there is a wide and close competition for the position, which is a fairly lucrative one.

A TRANSATLANTIC hygienist calls attention to the danger to the public health entailed by the practice of waving handkerchiefs on occasions of public excitement. At a recent popular reception given to President McKinley he estimates that there were 20,000 persons, of whom at least 4,000 were tuberculous, and he wisely declines to form even an approximate estimate of the myriads of tubercle bacilli that the ovation must have been the means of setting afloat.

PERSONAL.

By invitation of His Excellency, Sir William Stokes had a farewell interview with the Lord Lieutenant of Ireland before leaving for South Africa last week.

THE Royal Society having selected Drs. Stephens and Christophers, who have recently returned from Central Africa, to serve on the Commission of Investigation of Malaria, those gentlemen left this country last week for Sierra Leone.

HULL has lost one of its leading citizens by the death from pneumonia of Mr. Henry Thompson, L.R.C.P.Lond., M.R.C.S. He was highly popular with all classes, held several honorary appointments, and was in possession of an extensive private practice.

DR. LIONEL WEATHERLY, of Bath, has handed the sum of £150 to the Mayor's Transvaal Fund for the sick and wounded as the proceeds of his company of amateurs, who recently gave a performance of "Our Boys" at the Theatre Royal, Bath.

MR. WILLIAM CADGE, F.R.C.S., the well-known surgeon of Norwich, whose death was announced in most of the newspapers as having occurred on December 23rd, has written to the *Times* a letter of thanks for kindly expressed references, which, however, at present are premature. We would echo the wish that their need may long be deferred.

A GENTLEMAN, who for the present wishes to remain anonymous, has generously offered to equip at his own expense a field hospital for South Africa, sufficient to afford accommodation for 100 patients, the hospital staff to consist of four civil surgeons, four nurses, and the usual complement of ambulance men, and other supernumeraries. The offer is greatly appreciated by the authorities, and has been accepted.

FROM South Africa two items of medical interest reach us. Sir William MacCormac has left the camp at the Tugela River and gone to the Western Border to inspect the medical arrangements; whilst Surgeon-Major Burtchall, M.B., B.Ch., who was captured under a flag of truce at the Orange River, has been released by General Cronje.

THE post of Principal Medical Officer to the Local Government Board, which has become vacant by the death of Sir Richard Thorne-Thorne, carries a salary of £1,200 per annum, rising after five years to £1,500. It is expected that Mr. William H. Power, M.R.C.S., who has been for some years assistant Medical Officer to the Board, will receive the appointment.

DR. ED. TAYLOR JONES, D.Sc., has been appointed professor of physics in the University College of North Wales. In 1892 he took the B.Sc. degree with first-class honours at the University of London. With the aid of a Research Scholarship he proceeded to Berlin, where he carried on research work at the Physical Institute, which he embodied in 1895 in a thesis entitled "Electro-Magnetic Stress," and obtained the doctorship of science from the London University as his reward.

THE medical profession is moderately represented in the list of New Year's honours for the last year of the century. Dr. Lauder Brunton, and Surgeon-General F. K. Lovell, of Trinidad, have been created knights. The Hon. J. A. Cockburn, M.D., Agent-General for South Australia, has been created Knight-Commander of the Most Distinguished Order of St. Michael and St. George. Mr. John Pringle, M.B., Member of the Privy Council of Jamaica, has been appointed Commander of the same order, together with Dr. Patrick Manson. A similar distinction has been conferred upon Wordsworth Poole, Esq., M.B., for services rendered as Principal Medical Officer of the West African force on the Niger.

Of the foregoing the name best known in the medical world is undoubtedly that of Thomas Lauder Brunton, whose well-deserved promotion will be hailed with pleasure by a large circle of friends. Dr. Brunton originally took the M.B. of Edinburgh University in 1866, and he now enjoys the almost unique distinction of holding the degrees of LL.D. (Aber.), D.Sc. (Edin.), and M.D. (Edin.). He is the oldest lecturer on *Materia Medica* in London, and for many years acted as Assistant-Physician to St. Bartholomew's Hospital, but has comparatively recently received the post of full physician. He has held various examinerships at the Universities of Edinburgh and London, the Victoria University, and the Royal College of Physicians. He is the author of many well-known books on *materia medica*, therapeutics, and medicine generally. Among other accomplishments Sir Thomas Brunton has a perfect

command of the German language, which serves him in good stead at the International Medical Congresses, where he is a constant attendant. He is to be heartily congratulated in this latest recognition of a life that has been dedicated to sound professional work.

No little surprise has been occasioned in some quarters by the omission of Professor T. R. Fraser's name from the New Year's list. There are two possible explanations for this omission of a name that is in some ways one of the most distinguished in medicine. The first is that it may be forthcoming in a supplementary list. The second that a higher honour than that of knighthood is under contemplation.

THERE are, or will be, several vacancies in the staffs of London general hospitals. Owing to the resignation of Sir Douglas Powell a physician will shortly be required at the Middlesex. Within the next few months, by the retirement rule, both Dr. Sidney Ringer and Mr. Christopher Heath will leave University College Hospital, so that a surgery and a physiciancy will be vacant there. The sudden death of Sir Thorne Thorne will leave a lectureship open at St. Bartholomew's Hospital College.

THE "PURSER" TESTIMONIAL.

THE present and past pupils of Professor Purser, of the University of Dublin, together with a number of the leaders of the profession in Dublin, entertained him on Thursday last at dinner at the Shelbourne Hotel, Dublin, and he was then presented with the first copy of the medal established in his honour by the subscribers for the candidates who score the highest marks in physiology and histology at the University M.B. examination.

The Chair was occupied by J. W. Moore, M.D., President of the Royal College of Physicians in Ireland. After the usual loyal toasts had been proposed and responded to,

Sir CHRISTOPHER NIXON proposed the health of Dr. Purser in a most eloquent speech. Sir Christopher dwelt on the fact that although in the Dublin School clinical teaching had been always of a high order of excellence, yet teaching in its scientific aspects could only be said to date from the appointment of Dr. Purser to the chair of the Institute of Medicine, in the University of Dublin, some 25 years ago. Scientific Physiology and Histology were really first taught in Dublin by Purser. Besides this, for many years he voluntarily gave a course of Practical Pathology to the students, which was characterised by his usual thoroughness, and fully justified the saying that he has devoted his life to his pupils.

The toast was received with great applause.

Professor PURSER in reply said that his heart was full of emotion from the kind way his health had been received, and from the kind things which had been said of him. Still he thought that he would be other than human if he did not feel proud of the honour which had been done him. He felt that it was certainly the highest honour which had ever been paid to him in his life, and must he thought mark the climax of his career. Perhaps it might be thought that some account of his stewardship during this last twenty-five years might be required of him. He thought that physiology was far from occupying that place in the University which it should do, but there appeared to be better times in store for it. He could not enter on the retrospect which might possibly force him to introduce a discordant note which he would like to keep far from this meeting. However, that better things were in store for physiology he felt sure, but he was equally sure that they were not for him. He would be satisfied if he could but see the land of promise from the far side of the valley, and know that the students of the future were enjoying it. He felt that he had failed in many things, but he had always tried to

do his best. He thanked the students, his friends, and all concerned for the very high honour they had paid him.

The President then handed the first copy of the medal which had been founded by his past pupils to Dr. Purser.

The medal, a bronze brass, has a striking portrait of Dr. Purser on one side, and on the other the college arms.

It is to be given annually at the half-yearly M.B. examination in Trinity College to that student who, at the June examination gets highest marks in histology and physiology.

Obituary.

SIR JAMES PAGET, BART.

ON Saturday night, December 30th, Sir James Paget died peacefully in his house at Regent's Park. His end came at the ripe age of 85, and for many years past he had been regarded as the leading figure in the medical world. His honours were many and varied, his intellect and acquirements of a high order, and his interest in religious and philosophical matters no less sincere than profound. On the whole it may be safely said that in Sir James Paget the medical profession has lost one of its most interesting personalities.

The deceased baronet was son of a merchant of Great Yarmouth, where he was born on January 11th, 1814. He received his medical training at St. Bartholomew's School, and took the membership of the Royal College of Surgeons in 1836. Seven years later he was made an honorary Fellow of the same body when that distinction was first created. In 1866 he was elected honorary Fellow of the Irish College of Surgeons, and M.D. of Dublin in 1887. Among other distinctions he was created D.C.L. Oxon.; LL.D. Cambridge; LL.D. Edinburgh; Fellow of the Royal Society; and Fellow of the Royal Society of Edinburgh. After 1884 he was for some time Vice-Chancellor of the University of London. About the year 1860 he was appointed Surgeon to the Prince of Wales, whom he attended in 1872 during the attack of enteric fever that caused great national anxiety at the time. In 1871 he was created a baronet, and six years later the Queen conferred upon him the crowning honour of his professional career by appointing him her serjeant-surgeon. He was President of the Medical Society in 1875 and 1876.

Sir James married a daughter of the Rev. Henry North in 1844. He leaves three sons, Mr. Stephen Paget, who, as a surgeon, inherits much of his father's insight and literary ability; the Rev. Luke Paget, an eloquent and earnest clergyman; and Mr. John Paget, who succeeds to the baronetcy at the age of fifty-one.

Sir James Paget had a wide range of intellectual life, which carried him into many literary and philosophical directions. His power of expression, whether by the pen or in words, was unrivalled for clearness and grace. His eloquence, indeed, was of the first rank, but his speeches, it is interesting to note, were always carefully prepared beforehand and committed to memory. Many of his magazine contributions were perfect specimens of soundly informed and well-reasoned essays in perfect literary form. His best-known contributions to medical literature were "Lectures on Surgical Pathology," and "Clinical Lectures and Casebooks." He also drew up the first of the famous catalogues of St. Bartholomew's Museum.

As a surgeon Sir James was sound, conscientious, and painstaking. He never fully attained, however, the standard of brilliancy in operation that has been associated with most of our brilliant surgeons. At the same time his powers of diagnosis were of a rare and almost intuitive nature. For many years past he had given up all operative work, and since he left the well-known house in Harewood Place some years ago he abandoned altogether the practice of his profession.

The death of this distinguished surgeon, kindly and genial in his private relations, will leave a gap in many circles, professional and social, that will not readily be filled. His connection with St. Bartholomew's Hospital was a

long and close one. He filled the posts of Warden, assistant-surgeon, and surgeon, besides being lecturer upon anatomy, physiology, and surgery at various times. Upon severing his connection with the school in 1873 his portrait was presented to Lady Paget, who gave it to the hospital, where it now hangs.

At the Royal College of Surgeons Sir James served all the offices of importance with the exception, curiously enough, of that of examiner. In 1847 he was Arris and Gale Professor of Human Anatomy and Surgery; in 1865 he was elected a member of the Council; in 1873-4 he served as Vice-President; and in 1875 filled the presidential chair. From 1876-81 he represented the College on the General Medical Council; he delivered the Hunterian Oration in 1877, the first Bradshaw Lecture in 1872, and the first Morton Lecture on Cancer in 1887. He was appointed a trustee of the Hunterian Collection in 1885. A fine bust of this ornament of the medical profession was executed by Boehm in 1886, and stands in the College of Surgeons.

Correspondence

We do not hold ourselves responsible for the opinions of our Correspondents

THE EMPLOYMENT OF EMMENAGOGUES.

To the Editor of THE MEDICAL PRESS AND CIRCULAR

SIR,—As a medical practitioner of some experience I must protest against the tone of your paragraph under the above title in your issue of the 27th instant. Excluding pregnancy, ovarian disease, and mechanical obstructions, there are many cases of functional amenorrhœa that fall within the scope of treatment by drugs. The anæmia or other abnormal blood condition often present is possibly, as pointed out by Dr. Murrell, in your own columns a few weeks since, a symptom rather than a cause, just as in the parallel case of the anæmia that goes with constipation.

If by "emmenagogues" we understand substances that stimulate the non-gravid uterus, and turn to the list of such drugs given in any ordinary materia medica we find myrrh, aloes, ergot, alcohol, cantharis, digitalis, cimecifu, purgatives, hæmatinics, and tonics. As a general rule the administration of any of the foregoing will prove disappointing, and to that extent there may be some small excuse for the editorial attitude of doubt. It does not follow, however, that other drugs are not capable of remedying functional amenorrhœa.

The list given above is taken from a standard work on *Materia Medica* (a), but for all that it is like the play of "Hamlet" without the noble Dane, for it leaves out the most efficient, if not the only efficient remedies of the kind. The active drugs are manganese and senecio. Permanganate of potash, as an emmenagogue, has been before the profession for some fifteen years or more, but there is no doubt that the citrate of manganese introduced by Dr. Murrell is a much more trustworthy preparation. Senecio is the common ragwort; one of the class of composites. It is given in the form of a tincture made with proof spirit in doses of one to two drachms. Dr. Murrell's paper upon the action of those two drugs in functional amenorrhœa, backed as it was with numerous cases, forms one of the most suggestive and valuable contributions ever made to our knowledge upon an obscure yet most important subject. The appearance in the same journal a fortnight later of editorial views apparently of so contradictory and inconsistent a nature, has seemed to the present writer to require some further explanation.—I am Sir,

A BELIEVER IN DR. MURRELL'S EMMENAGOGUES.

Warwick, December 31st, 1899.

[Our paragraph does not traverse Dr. Murrell's conclusions, but was intended to emphasise the worthlessness of emmenagogue remedies—so called—as usually prescribed. We regard the question as still open.—ED. M. P. & C.]

Literature.

ROSE AND CARLESS'S SURGERY. (a)

THE phenomenal event of an annual re-issue of a text-book of surgery in this era of unlimited competition among authors—as well among other candidates for public favour—is in itself a very striking fact in the progress of scientific evolution. The extremely prepossessing volume before us appears to have secured this enviable success. The first edition appeared last year, and judging from the rate at which the present issue is being bought up at the schools of which we have some knowledge, there can be little doubt of its correspondingly rapid exhaustion. The history of this text-book has well justified the ambition of the authors, who state in their modest preface to the first edition that "we have endeavoured to meet what we think is at the present time a genuine need." Highly as we thought of the volume then, we confess that we did not anticipate—in presence of the boundless competition which existed, and the number of failures, and very limited successes in the same department with which our memory supplied us—that it was destined to become, as it has, the guide-book of the present generation of students and practitioners. We are now, of course, wise after the event, and can easily see why it is so. The authors themselves stated that it had been their "aim to present the facts of surgical science in a concise and succinct form, so as to satisfy the needs of the student, even of those who are preparing for the higher examinations. At the same time, the requirements of the general practitioner have not been overlooked. . . ." Such having been the aim of the authors we have only to admire the skill by which the goal has been obtained. We cannot refrain from paying our tribute of respect to the good sense with which "historical and bibliographical references have to a large extent been omitted, whilst diseases of special regions, such as the eye, ear, and female genital organs, are also practically excluded, except in so far as they encroach on the domains of general surgery." The busy, impatient student and the busy anxious practitioner have no time for such information in their every-day *vade-mecum*, and the judicious omission has rendered much valuable space available for a better purpose.

With regard to the special features of the present edition the authors inform us that "The whole of the text has been most carefully and thoroughly revised; many slips, necessarily present in a first edition, have been removed; a considerable amount of new material has been incorporated, so that we trust this edition may be looked upon as fully up to date. Many of the illustrations have been redrawn, others omitted, and new ones have been added." The result now placed before us is a tastefully bound, beautifully printed, and richly illustrated volume of 1,190 octavo pages. The last eighteen of these are occupied by an excellent index—a most important feature in the reference volume of the student and busy practitioner. The illustrations number 400: they are well-chosen, well-executed, and admirably suited for the elucidation of the text in which they are respectively placed; whilst the publisher's department is beyond praise.

Within the circumscribed limits of text books like the volume now under discussion it is, of course, utterly impossible to attempt to deal with varying opinions on the very many topics of surgical uncertainty. The authors have done wisely and well in the interest of their readers in skimming the cream from the still fluid mass of surgical debate and serving it up in the most inviting form for the mental nutrition of their disciples. Every captious critic will, of course, be able to persuade himself that some of the sections with whose subject-matter he happens to be more familiar than with the rest of the volume, might be easily improved by slight

(a) "A Manual of Surgery for Students and Practitioners." By William Rose, M.B., B.S. Lond., F.R.C.S., Professor of Clinical Surgery in King's College, London, and Senior Surgeon to King's College Hospital, &c.; and Albert Carless, M.S. Lond., F.R.C.S., Surgeon to King's College Hospital, and Teacher of Operative Surgery in King's College, London, &c. Second edition. London: Baillière, Tindall, and Cox. 1899. 21s. net.

alterations and additions. But upon the whole the effect upon our own mental vision is almost unqualified admiration. If there is any portion of the work which we would like to receive special attention when preparing the next edition, it would be the part which deals with the very familiar subject of fractures and dislocations. "Dupuytren's fracture" is hardly defined with sufficient clearness, and the figure given does not indicate the displacement which actually occurs. (Pp. 440-441). The paragraph which deals with "Displacement of a Semilunar Cartilage" should—in the light of recent literature—have been more carefully revised. But remarks of this kind are merely a suggested paring of the nails, to show our anxiety to contribute a very little to the almost perfect toilet of an ideal scientific text-book. Accordingly, we will not encourage ourselves to proceed further in this direction. Judging from the conscientious care which the authors have very obviously expended in correcting the small blemishes of the former edition, and making the present issue in every way worthy of the appreciative patronage which its predecessor received, we will anticipate in the coming edition the nearest approach to an ideal handbook for the over-worked student and the busy practitioner, of which our profession has hitherto been able to avail itself. We cannot help contrasting—with some bitter recollections—the volume before us with the corresponding one of our own student days. We heartily congratulate the authors on the well-merited success of their joint labours, and have no hesitation in predicting that with the continued exercise of the same care and judgment they will continue to be the most responsible apostles of surgical doctrine in the opening years of the twentieth century.

HEALTH RESORTS OF EUROPE (a)

THE fact that Dr. Linn's little guide is now in its seventh year of publication, forms ample evidence that it fills a distinct place among the numerous guides purporting to be of service in the selecting of a suitable health resorts.

The book is evidently intended for the ordinary layman as well as for the physician. It is addressed to "invalids going to some European watering-place, or intending to winter in one of the health resorts abroad." Such, however, are warned to "see a medical man before doing so, and not to take counsel of some kind friend who may have been benefited by taking such and such waters, or by living in a certain climate." It is comforting to find that "the family doctor can form a pretty accurate opinion from analysis of waters or meteorological data as to the locality indicated in each case; and no person should come abroad without having competent professional advice, with a written diagnosis or history of his case as well as a probable prognosis."

The "introductory hints and advice" on such points as the time to select for travel, preliminary treatment, clothing, beverages, cost of living, fees, &c., are sensible and suggestive, and will prove useful to inexperienced voyagers.

An alphabetically-arranged list of the various kinds of "cure" is given, and there is also a "Therapeutical Index and Dictionary" from which one can choose a station suitable to the special malady.

The descriptions of the various health resorts and their particular features and beneficial influences are arranged alphabetically under the heads of the different European countries. The actual information respecting the places is, in many cases, somewhat meagre, but the details as to length of journey and travelling expenses from London are given in practically every case, and for this alone the book will prove of the greatest convenience for ready reference.

As far as we have been able to ascertain the information given is fairly accurate. From the invalid's point of view it will form a useful supplement to Bradshaw.

The appendices are somewhat curious. They consist of a list of the officials of the British Balneological and Climatological Society; lists of hydropathic establish-

ments, sanatoria, and private clinics in Austria, France, Germany, Great Britain, Italy, and Switzerland; names of members of the Continental Anglo-American Medical Society and the American Dental Society of Europe; and, lastly, an alphabetically arranged list of the homes in England for the cure of intemperance.

There is an all-too-brief index. Needless to say there are many pages of advertisements, which, it must be admitted, are not without considerable interest to the reader, as well, doubtless, as of some value to advertiser and publisher.

The volume, in spite of its advertisements and business style, cannot but prove of service to the physician, and assistance to the invalid traveller.

Medical News.

The Gresham Lectures.

DR. E. SYMES THOMPSON, Gresham Professor of Medicine, will deliver a course of lectures on "The Perceptions," on January 16th, 17th, 18th, and 19th, 1900, at 6 p.m. each day, at Gresham College, Basinghall Street, London. These lectures are free to the medical profession and to the public generally.

Vital Statistics.

THE deaths registered last week in thirty-six great towns of England and Wales corresponded to an annual rate of 27.5 per 1,000 of their aggregate population, which is estimated at 12,786,832 persons in the middle of this year. The deaths registered in each of the last four weeks in the several towns, alphabetically arranged, corresponded to the following annual rates per 1,000:—

Birkenhead 22, Birmingham 28, Blackburn 19, Bolton 23, Bradford 21, Brighton 35, Bristol 25, Burnley 19, Cardiff 24, Croydon 22, Derby 20, Dublin 42, Edinburgh 19, Glasgow 23, Gateshead 21, Halifax 23, Huddersfield 17, Hull 23, Leeds 18, Leicester 24, Liverpool 33, London 29, Manchester 23, Newcastle-on-Tyne 24, Norwich 22, Nottingham 25, Oldham 21, Plymouth 38, Portsmouth 42, Preston 36, Salford 26, Sheffield 23, Sunderland 29, Swansea 36, West Ham 20, Wolverhampton 35. The highest annual death-rate per 1,000 living, as measured by last week's mortality, were:—From measles, 2.3 in Birkenhead, 2.4 in Hull, and 4.9 in Preston; from whooping cough 1.7 in Leicester, and 1.8 in Liverpool; from "fever" 1.1 in Portsmouth and in Nottingham, and 1.3 in Preston; and from diarrhoea, 1.4 in Burnley. In none of the large towns did the death-rate from scarlet fever reach 1.0 per 1,000. The 128 deaths from diphtheria included 54 in London, 15 in Sheffield, 8 in Leeds, 5 in West Ham, 5 in Portsmouth, 4 in Cardiff, 4 in Manchester, 4 in Birmingham, 4 in Blackburn, and 3 each in Dublin, Brighton, Swansea, Leicester, and Bradford. Eight deaths from small-pox were registered in Hull, but not one in any of the other large towns.

Lifebuoy Soap for the Troops in South Africa.

WE are asked to publish the following item of news:—Messrs. Lever Brothers, Limited, of Port Sunlight, have offered, and the Secretary of State for War has accepted, 5,000 tablets of Lifebuoy Royal Disinfectant Soap for the use of our troops in South Africa. The soap has accordingly been despatched to the Red Cross Commissioner at the front. The hospital and ambulance department of the Canadian contingent was also supplied with Lifebuoy Soap from the Toronto branch of Lever Brothers, Limited. The value of a disinfectant soap of such a recognised reputation and efficacy for use in our field hospitals is self evident, and the gift is sure to be much appreciated.

The Mortality of Foreign Cities.

The following are the latest official returns, and represent the last weekly death-rate per 1,000 of several of the populations:—Calcutta 27, Bombay 58, Madras 43, Paris 20, Brussels 17, Amsterdam 15, Rotterdam 15, The Hague 15, Copenhagen 16, Stockholm 15, Christiania, 15, St. Petersburg 25, Moscow 24, Berlin 16, Hamburg, 16, Dresden —, Breslau 22, Munich 24, Vienna 17, Prague 23, Buda-Pesth 17, Trieste 28, Rome 21, Turin (11 days) 19, Venice 24, Cairo 31, Alexandria 25, New York (including Brooklyn) 16, Philadelphia, 17.

(a) "The Health Resorts of Europe. A Medical Guide to the Mineral Springs, Climatic, Mountain, and Seaside Health Resorts; Milk, Whey, Grape, Earth, Mud Sanit. and Air Cures of Europe." By Thomas Linn, M.D. Pp. 271. London: Henry Kimpton, 1899.

Notices to Correspondents, Short Letters, &c.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

DR. CURTIN.—Yes, we regret to say that the evil reptile that has its being under the name of Christian Science is still to the fore in the United Kingdom. It is nevertheless somewhat surprising that it should have penetrated into so remote a hamlet as that mentioned. An American writer has summed up the tenets of this very peculiar faith in the sentence: "It received its name in 1876, and was a conglomeration of spiritualism, homoeopathy, mesmerism, deceit and avarice." There is much to consider in your contention that a more efficient General Medical Council and an amended Medical Act would soon rid the country of such pests and parasites.

A CLEVER YOUNG DOCTOR!

A CORRESPONDENT sends us the following clipping from the *Christian Budget* for December 29th:—"The very clever young doctor who attended Lady Salisbury, at her special desire, is only twenty-seven years of age, but he has already a very large practice." The world is probably listening with bated breath to hear the name of this "clever young doctor of twenty-seven." Will some reader send enlightenment?

ENQUIRE.—We understand there are over 400 medical men in Toronto, so there can be no great opening there. Our correspondent, however, had better write to someone living on the spot.

THE "MEDICAL DIRECTORY" FOR 1900.

We are asked by Messrs. J. and A. Churchill, publishers of the "Medical Directory," to announce that a disastrous fire at the printers has caused the destruction of the sheets and type. Steps are being taken to replace these, but a delay in sending out the subscribers' copies is inevitable. They hope, however, to publish the volume for 1900 early in February.

DR. DESPREZ.—It has been estimated that the provision of light for school purposes should be equivalent to that admitted by a window 1 yd. square for every 10 sq. yds. of floor, but this of course must be taken in conjunction with the proper distribution of the light.

ARMY MEDICAL DISPENSERS.

In our annotation last week we are made to state that the pay of army dispensers under the new arrangements would be ls. 6d. per day. The amount should have been stated as 5s. 6d. per day.

ERRATUM.—In the review of "Campbell on the Nervous System," in our last impression, please read "Campbell Thomson on the Nervous System."

OUR PARIS CORRESPONDENCE.—Owing to the irregular nature of the Channel service, occasioned by the stormy weather our weekly budget from Paris only arrived as we were "at press," too late for present issue.

DR. E.—De Sanctis states that the result of a large number of observations has been to show that dreams are more frequent in women than in men. Out of 160 men 50 dreamed rarely, 27 often, and 13 constantly; of 100 women 50 dreamed constantly, 45 often, and 13 rarely. Commenting on the expression to "sleep the sleep of the just," he remarks that the greater the criminal the better he sleeps, in fact, the ability to sleep is in inverse proportion to "cerebrality," and from this point of view professional criminals are low down in the scale.

Meetings of the Societies and Lectures.

WEDNESDAY, JANUARY 3RD.

OBSTETRICAL SOCIETY OF LONDON.—8 p.m. Specimens will be shown by Drs. Eden, Macnaughton-Jones, John Phillips, and others. Paper—Dr. Herbert Spencer: Four Cases of Rupture of the Uterus successfully treated by Packing the Tear per Vaginum with Iodoform Gauze.

THURSDAY, JANUARY 4TH.

HARVEIAN SOCIETY OF LONDON.—8.30 p.m. Clinical evening. **HÖNTEGEN SOCIETY** (20, Hanover Square, W.)—9 p.m. Mr. Chisholm Williams: The Interpretation of Skiagraphs.

FRIDAY, JANUARY 5TH.

LARYNGOLOGICAL SOCIETY OF LONDON (20, Hanover Square, W.).—4.30 p.m. Annual general meeting. Lantern demonstrations of Normal and Pathological Preparations of the Nose and Throat will be given by Dr. Watson Williams and Dr. Jobson Horne. Cases will be shown by Sir Felix Semon, Mr. Waller Spencer, Dr. Fitzgerald Powell, Dr. Herbert Tilley, Mr. L. A. Laurence, Mr. Stephen Paget, Mr. Lake, and others.

MONDAY, JANUARY 8TH.

ODONTOLOGICAL SOCIETY OF GREAT BRITAIN.—Special meeting for the purpose of considering the following proposed new bye-law, which has been recommended by the Council:—"That the Council be empowered to make Grants in aid of Scientific Research in connection with Dentistry." After disposal of the above, the meeting will be made ordinary for the adjourned discussion of Mr. J. F. Colyer's Paper on "Some Notes on the Treatment of Superior Protrusion."

Appointments.

FAGAN, A. St. L., L.R.C.P.Lond., M.B.C.S., Medical Officer for the Upper Holloway Central District, London.
FLEMING, G., M.B., C.M., M.B.C.P.E., Medical Officer for the Omberley District of the Droitwich Union.
GOUGH, J. Harley, F.R.C.S.Ed., L.R.C.P.Lond., Honorary Physician to the Western Hospital for Consumption, Torquay.
HILL, A. A., L.R.C.P., L.R.C.S.Ed., L.F.P.S.G., Certifying Surgeon under the Factory Acts for the Urban District of Tunstall.
LYDD, E. E., L.R.C.P.Lond., M.B.C.S., Assistant Medical Officer for the Infirmary of the Parish of Fulham.
ROSE, GEORGE, M.B., C.M., D.F.H.Aberd., Surgeon to the Royal Aberdeen Hospital for Sick Children.
ROWLANDS, W. H., L.R.C.P.Lond., M.B.C.S., Medical Officer of the Workhouse, Bromsgrove Union.
STURROCK, A. Corsar, M.A., M.D. Ed., Resident Medical Officer to the Royal Infirmary, Manchester.
THOMPSON, WALTER, F.R.C.S.Eng., L.R.C.P.Lond., Honorary Surgeon to the Hospital for Women and Children, Leeds.
WOOD, E. STANLEY, L.R.C.P., M.B.C.S., Medical Attendant at the Borough Infectious Diseases Hospital at Cambridge.

Vacancies.

Central London Ophthalmic Hospital, Gray's Inn Road,—House Surgeon. Salary at the rate of £50 per annum, with board and residence in the Hospital.
City of London Hospital for Diseases of the Chest, Victoria Park, E.—Second House Physician for six months. Salary at the rate of £30 per annum, with board and residence.
City of York.—Medical Officer of Health. Salary £400 per annum. Apply to the Town Clerk, Guildhall, York.
County of Sutherland.—Medical Officer of Health for the County of Sutherland. Salary £300 per annum, and £50 in lieu of travelling and other expenses, with certain exceptions. Applications to the County Clerk, Golspie.
Leicester Infirmary.—House Physician for 12 months. Salary £100 per annum with board, apartments, and washing.
Middlesex Hospital, W.—Assistant in the Cancer Research Laboratories. Salary £100 per annum, with an honorarium of £50, after second year of office.
National Hospital for the Paralyzed and Epileptic, Queen Square, Bloomsbury, London.—House Physician. Salary £100, with board and apartments.
Parish of St. Mary, Islington.—Medical Superintendent for the new Infirmary at Highgate Hill. Salary £500 per annum, with unfurnished residence, coals, gas, and washing. Applications to the Clerk to the Guardians, St. John's Road, Holloway, N.
St. Mary's Children's Hospital, Plaistow, E.—Senior Resident Medical Officer for one year. Salary £90 per annum, with residence in the hospital, board, and washing.
St. Marylebone General Dispensary, London, W.—Resident Medical Officer. Salary commencing at 100 guineas per annum, with furnished apartments, attendance, coals, &c.
Three Counties Asylum, near Hitchin.—Second Assistant Medical Officer. Salary £150 per annum, with board, apartments, washing, &c. Apply to the Clerk, St. Neots, Hunts.

Births.

BOKENHAM.—On December 25th, at Devonshire Street, Portland Place, London, W., the wife of Thomas J. Bokenham, M.B.C.S., of a daughter.
BROWN.—On December 27th, at 6, Gibson Square, London, N., the wife of George Brown, M.B.C.S.Eng., of a son.
HOLT.—On December 27th, at 18, Anglesey Crescent, Alverston, Hants, the wife of Surgeon-Captain Holt, R.A.M.C., of a son.
RUTHERFORD.—On December 30th, at 12, Newton Place, Glasgow, the wife of Henry Rutherford, M.B., of a daughter.
WHITE.—On December 30th, at 100, Lewisham Road, Lewisham, S.E., the wife of Malcolm White, M.B.C.S., L.R.C.P., of a son.

Marriages.

KYLE—WIGHT.—On December 29th, at the Anglican Church of St. John the Baptist, Buenos Aires, Juan Macdonald Kyle, M.D., of Conchillas, Uruguay, eldest son of Dr. J. J. Kyle, of Buenos Aires, to Margaret, youngest daughter of Henry P. Wight, of Bournemouth, formerly of Newcastle-on-Tyne. (By cable.)

Deaths.

CURTIS.—On December 29th, at Thanet House, Staines, Albert Curtis, M.B.C.S., L.S.A., second son of the late Frederick Curtis, in his 65th year.
LOCKETT.—On December 30th, of pneumonia, at 76, Herbert Road, Woolwich, John A. Pope, M.B.C.S., L.R.C.P., aged 38.
MEADE.—On December 24th, at Mount Royal, Bradford, Yorks., Richard Henry Meade, F.R.C.S., J.P., aged 85 years.
Ogilvy.—On December 23rd, suddenly, at Frimley Lodge, Frimley, Surrey, Surgeon-General John Ogilvy.
ORR.—On December 29th, at Wollaston, Wellingborough, James Wm. Orr, M.B.C.S., L.R.C.P.
PAGET.—On December 30th, after a few days' illness, Sir James Paget, F.R.C.S.Eng. and I, M.D.Dub., D.C.L.Oxon, LL.D. Cantab., F.R.S., Surg.-Surgeon to H.M. the Queen, Surgeon to H.R.H. the Prince of Wales, aged 85.

The Harben Lectures.

DIPHTHERIA

By PROFESSOR WILLIAM R SMITH, M.D., D Sc.,

F.R.S.Ed., BARRISTER AT-LAW,

President of the Royal Institute of Public Health, Harben
Lecturer for 1899.

ABSTRACT OF LECTURE I.

In the course of the three lectures which it is my privilege this year to give under the terms of the Harben Trust of our Royal Institute, I shall endeavour to deal as exhaustively as I can with that most interesting disease diphtheria—interesting to us from whichever point of view its study be approached, whether from the standpoint of its spread, its etiology, its treatment, or its prevention. And in thus dealing with the subject I shall have occasion to draw largely upon the experience I have obtained first as Medical Officer to the School Board for London, and secondly as chairman of the Medical Sub-Committee of the Metropolitan Asylums Board, to which sub-committee was entrusted the superintendence of the bacteriological examination of the diphtheria cases admitted into the hospitals of the Board over a prolonged period, and also the arrangements in connection with the preparation and supply of the antitoxic serum for the treatment of diphtheria cases.

From a study of the history of this disease there would appear to be no doubt that the disease has been known for many centuries, and, further, that one decided remission occurred (at the close of the eighteenth century) which was, however, followed by a sudden outbreak over a very greatly extended area.

In England the Registrar-General has only separately abstracted diphtheria deaths since the year 1855; up to that time such deaths as occurred were classified under the head of scarlet fever.

On examining the death-rates per million from diphtheria in England and Wales since 1855, and in London since 1859, we find that the deaths rose gradually during the years 1855, 1856, 1857, and then with a bound in the years 1858 and 1859; but during these latter years it should be noted that scarlet fever also was prevalent, and there may have been some inaccuracies in diagnosis. In 1860 the mortality fell nearly one-half, and after a recrudescence between 1861 and 1864 it fell almost continuously until it reached a minimum in 1872. There was a slight rise in 1874 to 1876, after which the rate again became very low both for all England and for London. From 1878, however, there was a steadily increasing prevalence, slow at first, but afterwards more rapid, especially in London. In 1893 the all-England rate reached 318 per million, which is the highest since 1859, and the London rate was as high as 761 per million, or more than double the rate in London in any previous year except 1892. Since 1893 the rates have shown a tendency to decrease; this has been most marked in London, and may be partially if

not wholly accounted for by improved methods of treatment

The diphtheria death-rates in England and Wales, and in London, in various periods up to 1897, for each of the first five years of age, and for groups of ages afterwards, show an enormous increase in the mortality for ages up to five, that in the London area during the periods 1881-90 and 1891-98 being most noticeable.

Diphtheria is more prevalent in temperate and cold regions than in the tropics, and in London both the mortality and the prevalence are greatest during the quarter ending December and lowest in the quarter ending June. Hirsch has shown that the same seasonal relationship exists in Sweden, Berlin, St. Petersburg, Vienna, and Philadelphia.

I now propose, in the first place, to draw particular attention to the evidence which can be obtained from statistics bearing upon the mortality from diphtheria in the past, so far as such statistics affect the country at large; I shall then deal more particularly with the statistical evidence available for London; and thirdly with that of other large European and American cities.

In the early history of the disease there is a distinctly marked tendency for the higher mortality rate to prevail in the less densely-populated districts; this Dr. Longstaff showed in a report published in 1887. The report reveals also an important change in the incidence of the disease, as judged by its mortality, in the latter periods for which the observations were made.

Death-rates from diphtheria according to density of population:—

Period.		Sparse.		Medium.		Dense.
1855-60	...	248	...	182	...	123
1861-70	...	223	...	164	...	163
1871-80	...	132	...	125	...	114

Dr. Longstaff obtained this table by grouping the registration districts of England and Wales under the headings of sparsely, medium, and densely populated, according to the relationship of the acreage to the number of the inhabitants, and it will be seen that, whereas in 1855-60 the rate in the sparsely-populated areas was more than double that in the dense districts, the rate in the decennial period 1871-80 had markedly fallen in sparsely populated localities, whilst it was almost at the same level as in the period 1855-60 in the more crowded parts of the country.

From a communication which I have received from Dr. Longstaff in this connection, I find that sometime ago he commenced to analyse the returns for the ten years 1881-90, with the result that he found considerable changes in the geographical distribution of the disease, but that so far as he went the figures did not seem to point to any very definite conclusions. He also informs me that the researches of Dr. Eig nbrodt, of Darmstadt, confirmed his principal result—viz., that diphtheria in its first incidence chiefly attacks rural districts—which he explains conjecturally as the consequence of hereditary pre-

disposition to throat disease intensified by breeding-in.

Not only, however, has the disease during the period for which observations have been recorded varied in its incidence on locality according to the density of population, but it has also varied in its incidence in England and Wales as a whole.

Looking at the figures for the whole country, we find that a sharp fall in the rate occurred in the decade 1871-80 as compared with the preceding period; in 1881-90 a rise occurred, but not sufficient to bring the rate to its level in 1861-70; but in 1891-98 a further rise took place, bringing the mean rate for the eight years to a higher figure than had been reached in any previous single year since 1864. The mean rate in 1860-64 was, however, slightly higher than that in the last eight years, and the rates in the two years 1858 and 1859 were higher than the rate in any one of the years 1891 to 1898. For the whole country, then, the diphtheria mortality in recent years has been high, but not so high as it was a generation earlier.

Turning, however, to the separate counties, remarkable variations are at once apparent. It is true that the decrease of mortality in 1871-80 was, with a few insignificant exceptions, shared by the whole country. But not so the increase of mortality of the periods 1881-90 and 1891-98, which was very considerably greater in the southern than in the northern parts of the country. This will be well seen if a line be drawn across the map of England, starting from Yarmouth, passing north and west of Suffolk, then south of Cambridgeshire, Hunts, Northamptonshire, Warwickshire, and Worcestershire east and north of Herefordshire, and along the line separating South from North Wales. In every one of the twenty-two counties to the south of this line the diphtheria rate was higher, either in 1881-90 or in 1891-98, than it had been in 1861-70; on the other hand, only five of the twenty-three counties to the north of the line—viz., Leicester, Staffordshire, Worcestershire, Lancashire, and Durham—had higher rates, either in 1881-90 or in 1891-98, than they had had in 1861-60.

A convenient method of showing the *distribution* of diphtheria through the country independently of its special severity at any time is to represent the rates of mortality in the various counties by the proportions they bear to the rate in the whole country at the same period. One of the most significant of the facts thus made prominent, is that certain counties have, in each of the four periods, had diphtheria death-rates exceeding that for the whole country. These counties are Surrey, Kent, Sussex, and Essex. The rate for London and for one other county (Middlesex) was less than that for the whole country in 1861-70, but greater in each of the other periods; and the rates for Shropshire and North Wales were greater than the rate for the whole country in the first three periods, but less in 1891-98.

If, with the aid of coloured and shaded maps, we attempt to trace the spread of diphtheria in the south-eastern corner of England, we find that in 1861-70 London—with a rate slightly less than that of the entire country—was partly surrounded on the east and south by counties whose diphtheria mortality was relatively high. In 1871-80 the mortality in London still remained practically equal to that of England and Wales (which had fallen by one-third), but the ring of relatively diphtheritic counties had become complete around it, and in the two following periods the mortality in London itself increased enormously. Another point which is clearly brought out is that although the death-rates from diphtheria in several of the northern counties exceeded the rate in the whole country in 1861-70 and 1871-80, the excessive mortality has, during the last eight

years, been confined to the south-eastern part of the country and to Monmouthshire and South Wales.

A general statement that the *southern counties* of England have suffered their highest diphtheria rates since 1881, and that the *midland and northern counties* (excepting Leicester, Lancashire, and Durham) had suffered theirs before 1871, is very near the truth; and it must be noted that this southern area includes not only London and the immediately surrounding counties, but a number of agricultural counties, which cannot by any stretch of the imagination be supposed to be constantly infected from London; and, on the other hand, the northern area of low diphtheritic rates since 1871 comprises thickly-populated towns and congeries of towns, in which all the influences of mere aggregation in the spread of the disease are likely to be more active than in London, and *far more active* than in such agricultural districts as Bucks, Oxfordshire, and Suffolk, counties whose recent diphtheria rates exceed those shown in any of the four periods in Lancashire.

Speaking generally we find that the mortality from measles, like that from diphtheria, declined in the decade 1871-80, and rose in 1881-90. Only four counties (Devonshire, Monmouthshire, and North and South Wales) showed *greater* mortality in 1871-80 than in the previous decade; and only seven (Devonshire, Monmouthshire, North Wales, Shropshire, Leicestershire, Lincolnshire, and Westmoreland) showed less mortality in 1881-90 than in 1871-80.

When, however, we inquire more closely into the matter we find a remarkable difference of behaviour between diphtheria and measles. The mortality in certain counties was greater than in the country as a whole during each of the four periods. These counties were London, Monmouthshire, Staffordshire, Lancashire, and Durham. The relative freedom of the southern counties from measles is as remarkable as the liability of several of them to diphtheria. The measles rate in Northamptonshire and in Cornwall exceeded the rate in England and Wales during 1861-70, and the rate in Devonshire was excessive in 1871-80, but these are the only cases in which the rate in any southern county except London has exceeded the rate for the whole country in *any one* of the four periods.

Applying the same line of reasoning to cases of scarlet fever, we find that the changes in scarlet fever mortality have been altogether of another kind, indeed the tendency throughout the country has been towards a rapid and continuous decline. In the country as a whole, the mortality in 1891-98 was only a little more than one-sixth of what it had been in 1861-70, and every single county shows a much lower rate in 1891-98 than in 1861-70. Indeed, only three counties fail to show a *successive* decline of mortality in the four periods covered by the table. Of these exceptions, the increase in the scarlet fever mortality of Middlesex in 1891-98 is probably accounted for by the establishment of the Metropolitan Asylum Board's Northern and North-Eastern Hospitals in Tottenham, while the others are too small to be of real importance.

Statistics show that the mortality in Staffordshire, Lancashire, the West Riding, Durham, and South Wales was in excess in each period, and in Cheshire, Northumberland, and Monmouthshire in three periods out of the four. It will be noted that Staffordshire, Lancashire, Durham, and Monmouthshire, occupy a similar unhappy pre-eminence in regard to measles also: while, on the other hand, Staffordshire, Lancashire, the West Riding, and Durham are among the counties whose diphtheria rates have in each period been below those of the whole country. The similarity of the local distributions of measles and scarlet fever, and their contrast with the loca

distribution of diphtheria, will be still more clearly seen by mapping them out, and by comparing the maps relating to diphtheria and measles with that of diphtheria.

The general result of such an examination appears to be that, although the spread of every infectious disease must necessarily be favoured by bringing together large numbers of those most liable to it, yet the conditions most favourable to the diffusion of measles and scarlet fever are not those most favourable to the diffusion of diphtheria. In other words, if we wish to explain why Sussex is comparatively free from measles (one of the most infectious, if not the most infectious, disease among children) and scarlet fever, but suffers from excessive diphtheria mortality, while Staffordshire is comparatively free from diphtheria but suffers excessively from measles and scarlet fever, we must look for some conditions which are not common to the two counties.

It may be suggested that such a condition is found in the fact that Sussex is much nearer to London than is Staffordshire; but this suggestion fails entirely to meet the case, since the special liability of Sussex to diphtheria began several years before that of London; and, moreover, Staffordshire shares the liability of London to excessive measles mortality, while Sussex does not. Again, if school infection is the chief cause of the mortality from diphtheria in Sussex, why should Staffordshire escape? And if school infection is the chief factor in the spread of measles and scarlet fever in Staffordshire, why should Sussex escape? It is evident that several agencies must be at work in spreading zymotic diseases among children, and it may be taken as highly probable that the vicinity of infected centres is one, and school infection is another of those agencies. But the comparison of the geographical distributions of three of these diseases strongly suggests that special local causes other than school attendance, or the neighbourhood of infected centres, have a potent influence in selecting the disease and promoting its diffusion.

Dr. Arthur Newsholme, in his book on epidemic diphtheria, demonstrates two facts very clearly: first, that London compares very favourably with the majority of these towns in regard to its diphtheria death-rate; and, secondly, that all towns, whether endemic centres of this disease or not, are liable at varying intervals to epidemic outbursts of a severe character, lasting over a period of several years. The value of the statistics thus brought forward is somewhat diminished from the fact that the only evidence attainable of the prevalence of the disease from year to year is from the number of deaths per 100,000 of the population, although the case mortality must have been subject to considerable variations, and is therefore not a true measure of incidence. As the author points out, however, notification has been in force for too short a period to afford trustworthy evidence of the prevalence of the disease over any considerable period of time. Again, it has been necessary in some cases to group together the mortality from diphtheria and croup, that from diphtheria alone not being forthcoming. In many cases, however, the death-rates from diphtheria alone are also available.

This author shows that:—

	Mean death-rate for	per 100,000,
New York ...	27 years of	109
Berlin ...	27 "	101
Boston ...	34 "	100
Christiania ...	33 "	80
Chicago ...	35 "	77

While the greatest mortality for any year in London was 76, this occurring in 1893. With regard

to the maximum annual diphtheria mortality in these towns, the figures are still more striking:

In 1887 the death rate of Christiania was 303 per 100 000; in 1883 the death-rate of Berlin was 220 per 100,000; in 1877 the death-rate of New York was 208 per 100,000.

While Boston and Chicago in America, Frankfort-on-Maine in Germany, Buda-Pesth and Vienna in Austria-Hungary, St. Petersburg and Moscow in Russia, Gothenburg and Stockholm in Scandinavia, all furnish death rates of considerably over 100 per 100,000. The highest corresponding figure for London, as previously stated, being 76.

When the combined death-rates from diphtheria and croup are examined, similar results are obtained, and the list of excessive mortalities is swelled by the returns from Buenos Ayres, Paris and Marseilles, Milan, Florence and Rome, Brussels and Antwerp, Dresden and Munich, and Trieste, in addition to those towns already mentioned.

In the case of Florence, the maximum mortality from these two diseases reached 422 per 100,000 in the year 1871, while the death-rate in New York, Chicago and Buenos Ayres, Milan, Dresden, Trieste, Christiania, and Gothenburg was above 250.

With regard to the maximum epidemic years of the different towns, Dr. Newsholme's figures show that not only were epidemics prevalent during different years in the different countries, but they occurred in different years in the various towns of the same countries; and in the case of Brussels there was a difference in this respect even between the city and its suburbs, for in the course of an epidemic which reached its height in 1862, the decline was some years later in the suburbs than in the city itself, and in fact, was scarcely over when a second epidemic over-ran the whole district, culminating in the year 1885.

Taking these figures into consideration, it is evident that, so far from there being at the present moment a formidable death-rate from diphtheria in London, this city has been spared in a remarkable manner from the lot which has fallen to most American and European cities of importance. Moreover, it seems possible that the present increase in the diphtheria death-rate may be accounted for by the occurrence of a period of epidemicity of the disease, mild at present as compared with that which has been experienced by the towns of other countries in previous years, this epidemicity being due to general causes, of which we have at present no knowledge, and which we therefore cannot hope to control until that knowledge is obtained.

Now what is the nature of this disease we call diphtheria? We recognise it to be a disease of a specifically infectious character, primarily affecting mucous membranes, and most commonly the upper portions of the respiratory and digestive tracts. At first it is a purely local inflammation, characterised by the formation of a false membranous deposit, the system only secondarily becoming affected. The disease is occasioned, as we now all know, by the reception at a particular point of the affected surface of the Klebs-Löffler *bacillus diphtherie*, which micro-organism must be considered as the specific and essential cause of the local complaint, whilst the general system is subsequently implicated owing to the absorption of the chemical poison or toxin, which is formed during the growth of the organism in the throat.

This organism is always found in connection with the false membranes associated with diphtheria, and for this reason, therefore, it becomes a question of prime importance that bacteriological tests should be applied in all cases of suspected diphtheria. The bacillus is extremely polymorphic, but two varieties may be noted—the long and the short.

Usually no difficulty occurs in recognising the diphtheria bacilli either upon the surface of the nutrient media or under the microscope, but occasionally a difficulty arises, for organisms closely resembling Klebs-Löffler bacilli are found in healthy and non-diphtheritic sore throats, which have been described as pseudo-diphtheria bacilli. Some observers give this name to organisms bearing a superficial resemblance to the true diphtheria organism, whilst others apply the term to organisms which morphologically cannot be distinguished from the typical bacillus, but which differ from it in so far as they fail to produce any pathogenic properties when injected into guinea pigs. The exact connection of these organisms with the true bacillus is not clearly understood.

The evidence justifying the assertion that the Klebs-Löffler bacillus is alone the cause of diphtheria is of a very interesting nature. True diphtheria apparently never arises spontaneously in the lower animals, with the single exception of the cat. In this animal, Dr. Klein, to whom we are much indebted for many able researches on the subject, has described a disease characterised by broncho-pneumonia, cardiac disease and ophthalmia, whilst in the consolidated portions of the lung he has found the diphtheria organism in considerable numbers. He consequently concludes that cats are susceptible to human diphtheria, and that in them the disease principally affects the lungs. He has also shown that inoculation of the conjunctiva or of the mucous membrane of the mouth of the cat with diphtheritic material is followed by changes closely resembling the disease in the human subject.

Our bacteriological knowledge of the disease has been greatly advanced by the enlightened policy of the Metropolitan Asylums Board, of whose work in connection with the treatment of infectious disease in London it is impossible to speak too highly. Consequently upon representations made to the Board, in which this Institute played no insignificant part, it was determined that not only should bacteriological tests be instituted in all cases of suspected diphtheria, but that so far as possible these tests should—at least, in the first instance—be made upon a uniform basis, the responsibility being centred in one person.

During the three years covered by the statistics kindly placed at my disposal, out of 12,173 cases, diphtheria bacilli were found at the last examination in no fewer than 4,052, or 33.28 per cent.; and if we note the figures for the different years, we find that:

In 1894 there were 25 such cases out of 45, or 55.5 per cent.

In 1895—1,594 such cases out of 5,296, or 30.1 per cent.

And in 1896—2,433 such cases out of 6,832, or 35.6 per cent., with the specific organism still in the throat at the last examination, and although it would be unfair to assume that all these cases had bacilli in their throats when discharged from hospital, yet doubtless in a fair proportion of the cases there can be no question that the organism was present, ready to be transmitted to those to whom the patient might come in contact. Bearing in mind the prevalence of diphtheria in London, and the fact that diphtheria can readily be transmitted by patients apparently well, this point would appear to have great importance from the danger to which such cases may expose the public. There, is, however, another practical point to be observed. It will be noted that there were a certain number of cases in which bacilli were not found at the first examination, but were demonstrated subsequently. From this it must be concluded that the diphtheria bacillus, though present, was overlooked. Occasionally infection may have taken place after the first examination, and a subsequent examination confirmed the

diagnosis, but the importance of making more than one examination is demonstrated in all cases where a doubt exists, especially in those where a negative bacteriological diagnosis is given.

There exist differences of opinion as to the influence on the course of the disease of different forms of diphtheria bacilli when present alone or in combination with streptococci and staphylococci. As regards the diphtheria bacillus alone, the highest mortality appears to be associated with the long bacillus, and in cases of mixed infection the most fatal form occurs when the bacillus is associated with the streptococcus group. The short bacillus would appear usually to have such slight virulence that it merely gives rise to a mild attack of sore-throat, but we must be careful to guard ourselves against the assumption that such cases do not contain specific infection, or that the throats in which they are found are not sources of infection; but in 148 cases in which the short bacillus was alone found there were only five deaths. In all cases it appears that mixed infections give rise to graver lesions than simple infections, even with the most virulent form of diphtheria bacilli.

In respect of the cases for 1895 and 1896 in which no diphtheria bacilli were found after repeated examinations it is worthy of note that in 3,236 cases, or 26.5 per cent. of the total cases examined during the two years 1895-96, no diphtheria bacilli were found, so that even allowing for errors of observation, over 20 per cent., or some 3,000 cases, were admitted to the Asylums Board's hospitals which offered no evidence, clinical or bacteriological, of diphtherial infection. The importance of these observations cannot be overstated, if only from the point of view of beds being occupied which could more properly be filled by genuine cases of diphtheria.

In that most fatal form of diphtheria, viz., hæmorrhagic diphtheria, the long and irregular forms of diphtheria bacilli were demonstrated in the throats of the patients, and in a large proportion of the cases there were staphylococci present either alone or in combination with the streptococci.

As a result of the observations made, the persistence of the diphtheria bacillus for periods up to eight weeks was of common occurrence, whether treatment by antitoxin was adopted or not, whilst the majority of cases seem to retain bacilli in the throat from two to nine weeks. After the ninth week the number appears to fall very rapidly. In the year 1895 two cases were found to have the infective bacillus present beyond 200 days—in one of these antitoxic serum was used; and a considerable number remained infective beyond 100 days.

In 1896 no cases were found in which diphtheria bacilli were present after the 189th day among the injected cases, and after the 169th day among the non-injected cases. Ninety-four still contained bacilli on the mucous membranes after the 100th day among the injected cases,

OTORRHOEA AND ITS TREATMENT.

By DR. PAUL RAUGE.

(Concluded from page 7.)

Treatment of Suppurative Otitis before Perforation of the Tympanic Membrane.—In spite of these precautions, supposing they have not been neglected, the microbes may pass through the Eustachian tube, determining infection and suppuration of the tympanum. As long, however, as the tympanic membrane is intact, the suppuration is going on in a tightly corked bottle, so to speak, the microbe to which the condition is due forming cultures in a state of purity, without any secondary

infection. This is the monobacillary stage, with which a suppurative otitis invariably begins. The question then presents itself, whether it is better to follow the old rule of evacuating pus wherever found, or, on the contrary, preserve the protective membrane which wards off the danger from outside. If this protection could be kept up indefinitely, and the contents of the tympanum were likely to be absorbed, there would be no doubt of the best course to be adopted. As a rule, however, an abscess which one hesitates to open to-day will open of its own accord to-morrow, and, such being the case, it is certainly preferable to have recourse to surgical means for evacuating the pus under the best possible conditions, rather than to run the risk of a spontaneous evacuation, which can neither be directed nor controlled.

There is perhaps no surgical operation which a medical man is so unwilling to perform as paracentesis of the tympanic membrane; yet, it is one of those which should be done most frequently, in the first place because it is an extremely easy one and absolutely harmless, and secondly because there are few operations which exert so marvellous an influence on the existing symptoms and threatening dangers. This operation, which after all is nothing more than a puncture with a needle, instantly alleviates the excruciating pain, saves the hearing of the patient, and prevents complications which may seriously threaten his life.

There is therefore no need for me to dwell upon the indications of paracentesis, for in my opinion there is but one, viz., the presence of pus in the tympanum. If the tympanic membrane is tense and yellowish, if it bulges toward the auditory meatus, and if severe pain exists, there is only one thing to be done, and that is to open the abscess without delay. The cavity of the tympanum being as yet but slightly infected, this simple incision should be performed under as rigorously antiseptic conditions, as if it were a question of entering the peritoneum or the pleura. The auditory canal should be carefully washed, first with soap, then with alcohol, and lastly sprinkled with a 1 : 1,000 mercury perchloride solution. The speculum and the needle should be sterilised either in an antiseptic bath or, better still, in the stove or by flaming. The needle used for the paracentesis consists of a simple steel rod, more or less inclined with reference to the handle, with an enlargement at the tip in the form of a lancet. The cutting edge of this tip should be subjected to a preliminary examination, either by a magnifying glass, or by trying it on a tightly stretched piece of an old kid glove, as is done with cataract knives, for on the condition of this edge depends the success of the perforation, and more particularly the degree of pain it causes. Moreover, although it is generally admitted that cocaine has no effect on the tympanic membrane lined with its epidermis, it is always well to instil, before the operation, a few drops of a strong solution (10 or 20 per cent.) of this anæsthetic.

With regard to the operative technique, it is sufficient to remember that the incision should always be made in the infra-umbilical region, where there is no important organ to look out for. The umbilicus corresponds exactly to the promontory, and as the width of the tympanum at this spot is only from $1\frac{1}{2}$ millimetres to 2 millimetres, the puncture should always be made lower down, near the floor, where the distance between the membrane and the inner wall of the tympanum is at least 4 millimetres. It is a matter of indifference whether the puncture be made in the anterior or posterior region of the lower half, whether the incision be horizontal or vertical, although the latter is somewhat better adapted to facilitate escape of the pus, and conforms better to surgical rules. The ear being well lighted and the head of the patient being held firmly by an assistant, the operator selects the spot for the incision, and with a sudden, determined movement the point of the needle is pushed in to the depth of 2 or 3 millimetres, and then withdrawn in a slightly inclined direction, in order to effect an enlargement of the opening as it is pulled out. Evacuation of the fluid is facilitated either by Politzer's douche, or by aspiration through the auditory meatus either with Siegle's pneumatic speculum or Delstanche's rarefactor. The dressing consists simply

in the introduction of a cotton pad, soaked in carbolic acid dissolved in water or glycerin, or preferably a strip of sterilised or iodoform gauze, which is frequently changed, in order to prevent stagnation of the fluids. Care being taken to thoroughly dry the auditory canal each time.

Treatment of Simple Otorrhœa.—After paracentesis of the membrana tympani, three conditions may present themselves; the surgical traumatism and the lesions which have necessitated it may heal immediately and completely; or the incision heals, but the abscess is reproduced, and the operation must be repeated, possibly several times, as long as the tympanic cavity still contains pus; lastly, the wound may remain open, the discharge persisting. Whether the fistula follows an incision or, as is more frequently the case, spontaneous perforation of the membrane, it shows that the affection is becoming chronic, and that the discouraging stage is entered upon, of which it is impossible to foresee the termination, no relief being obtainable except at the cost of a serious operation.

The treatment of otorrhœa is not only one of the most difficult tasks which may fall to the lot of the medical man, but also a source of continual anxiety. It is certainly humiliating to see a discharge from the ear continue for months in spite of all that may be done to stop it, and it is terrible when one knows that, as long as this suppuration persists, there is danger of its leading to complications with a fatal issue. Not that there are no means of combating the affection itself. On the contrary, they are too numerous, and we have only to choose between them, but the difficulty of the matter lies in being able to recognise when the moment comes for giving up dressings and irrigations, and having recourse to the knife and the curette. However much the various measures for treating otorrhœa may differ in detail, there are in reality only two distinct methods, diametrically opposed to each other, of dealing with this affection.

One is based on expectation, leaving the organism to drive back the pyogenic germs, eliminate the necrosed parts, and repair the loss of tissue, while medication is simply limited to sanitation of the battlefield, so to speak, carrying away the dead, sweeping out the morbid secretions, and barring the access to the diseased cavities by suitable dressings. This is the method of antiseptic defence.

The other is the method of active attack, in which the medical man does not content himself with merely insuring evacuation of the pus, doing away with its irritating effect, and preventing septic transformation, but endeavours also to destroy its source by chemical action on the mucous membranes which furnish it, or by removing by the aid of surgical operations the sequestra and necrosed tissues, which, here and elsewhere, by efforts at spontaneous elimination keep up the inflammatory reaction and persistent suppuration.

A beginning is invariably made by the application of an antiseptic treatment, which may be abandoned at any time sooner or later, according to the persistency of the lesions, the character of the symptoms, and the impatience of the patient. There are, in fact, only two things to do, to destroy the culture medium by removing from the affected cavities the fluid as it is formed, and to forestall complications by preventing the micro-organisms of secondary infection from gaining access to the tympanum. The treatment in this case is therefore reduced to cleansing of the ear and the application of a suitable dressing.

In spite of the severe criticism that has been made of irrigation of the auditory meatus, it remains the simplest and most generally employed method of cleansing the ear. Non-aseptic irrigations, which affect the tympanum, instead of cleansing it, are of course to be condemned under any and all circumstances; but it is well understood nowadays that any fluid introduced into the auditory meatus must be thoroughly sterilised, as well as the instrument used for the injection.

Pure boiled water answers very well for the merely mechanical effect of an injection of this kind, but it is customary to add certain substances for antiseptic purposes. I do not propose to weary the reader by a

list of the innumerable mixtures employed for irrigation of the ear; but as it is of importance to keep a few of them on hand, in order to be able, when one appears to lose its effect, to substitute another I shall mention those which practical experience has shown to be most efficacious:—

There are in the first place the three antiseptic solutions generally used, arranged in the order of their potency; the saturated boracic acid solution, the 1 per cent. carbolic acid solution, and the 1 : 1,000 mercury perchloride solution. These are indeed sufficient for the large majority of cases, provided one knows how to handle them and takes into account the peculiar deficiencies of each, viz., the weakness of the first, the irritating local action of the second, and the toxicity of the third.

A large number of other antiseptic substances are also employed, which, however, present no other advantage over those mentioned above than that they are new, and may occasionally replace them when a change is desired. The principal ones of these are: creolin (1 or 2 : 1,000), lysol (1 or 2 per cent.), phenosalyl (1 per cent.), resorcin (from 1 to 4 per cent.), salicylic acid (from 1 to 4 : 1,000), hydrogen peroxide, pure or diluted with from one to five times its volume of water, oil of turpentine (20 drops in one litre of water, Politzer). This, I think, is more than will ever be needed for varying the treatment at pleasure.

Whatever solution may be used, it is of the greatest importance to dry the auditory meatus well after each irrigation, either by insufflation of warm air, or with a cotton swab attached to a metal probe or held by a pair of forceps. It need hardly be stated that these tampons should be sterilised, that is to say, be passed through the disinfecting stove and preserved in closed glass jars, or flamed by the method described by Lermoyez and Helme, which consists in steeping the cotton swab in a saturated solution of boracic acid in alcohol and setting fire to it, the boracic acid preventing the cotton from burning. After a few seconds, the flame is extinguished, and the swab is then completely sterilised, or at any rate its surface is rendered sufficiently aseptic to do away with the danger of introducing into the meatus any germ of secondary infection.

Of late, however, irrigation of the middle ear has been the object of very unfavourable criticism. In the first place, the objection has been made that this irrigation is doomed to be incomplete, as it does not reach either the attic or the mastoid cells, and that on the whole it is only a surface irrigation, affecting principally the auditory meatus and but very little the deep cavities. This argument is not without force, for it is certain that a jet of liquid, however forcibly applied, can never be made to wash out thoroughly a blind duct, especially when the cavity is irregular. What is the result, for instance, of trying to wash out a bottle, without turning it upside down, simply by means of a continuous jet, passing through the neck? For irrigation of the ear to be really efficacious it would be necessary to have a counter-opening so as to permit the fluid to pass through it from one end to the other, and thus to clean out the contents. An attempt has been made to obtain this result by injecting through a catheter or a Weber-Liel sound introduced into the Eustachian tube, a quantity of fluid, passing through the tympanum and out through the auditory meatus. The attic is reached by inserting through the opening in the tympanic membrane one of Hartmann's bent catheters. In spite of these artifices, however, it must be admitted that the results of irrigation of the ear are not entirely satisfactory. It has even been alleged that this manœuvre merely results in driving the germs existing in the auditory meatus into the tympanum, and is therefore so dangerous that it is better not to employ it. Politzer long ago proposed to replace the liquid by a current of gas, and clean out the tympanic cavity with an air douche through the Eustachian tube. This measure, however, to which Gruber has long objected, has in its turn been accused, not only of removing much less pus from the tympanum than is generally supposed, but also of introducing into it microbes from the nasal cavities and pharynx. The opinion is therefore gaining ground that

no attempts should be made at cleaning out the tympanum either with water or air, simply "replacing all that" (Pes and Grad-nigo) by aseptic dressing of the auditory meatus. This dressing itself, like irrigation of old, tends to become more and more simple. Formerly it was the rule, after washing out and drying the ear, to blow in an antiseptic powder, boracic acid having been much used for this purpose on the recommendation of Politzer. The objection made to it, that it forms a paste and thus prevents the pus from escaping, does not hold unless it be employed in too large quantities. Very little should be used, only just enough to barely whiten the wall of the canal. The feeble antiseptic power of boracic acid has led to its being replaced by other, more active, substances, such as iodoform, which is indicated especially in tuberculosis, in spite of its disagreeable odour, aristol, dermatol, and salol. Like irrigation, however, insufflation of powder is gradually going out of fashion. A strip of iodoform or simply sterilised (Hamon du Fougeray) gauze, which is introduced to the farther end of the auditory meatus and drains the tympanic fistula, on top of this a layer of gauze, and, lastly, a bandage to keep it in place, such is the modern dressing of suppurative otitis, described by Pes and Gradnigo under the name of the "rational treatment."

The antiseptic dressing represents only an armed expectation, so to speak, or a respite accorded to the otorrhœa before combating it by operative measures. Before resorting to this *ultima ratio* of treatment, however, another series of local measures is usually tried, which are more potent than a simple dressing, but less aggressive than operation, being a sort of compromise between these two extremes. This is instillation of astringent or caustic fluids, constituting the modifying treatment, the aim of which is to change the structure of the secreting surfaces, to reduce the hypertrophied mucosa, to check its granulation, and possibly even to facilitate detachment of sequestra and cleansing of the carious surfaces. Among chemical caustics used in otology, silver nitrate is the one most frequently employed, either in strong solutions, graduated from 2 to 10 per cent., or in the form of a stick, or rather a small lump attached to the end of a metal rod. It unquestionably possess the property of reducing a too exuberant mucous membrane, and checking the production of fleshy granulations. The only drawback is the fact that it sometimes determines excruciating pain, especially when it touches a denuded bone or passes into the mastoid cavities. It is necessary, therefore, to gradually lead up to the use of strong solutions of this caustic, and to always take the precaution of first applying cocaine to the mucous membrane. To get the full effect of the remedy, it is not enough to use two or three drops, but the auditory meatus should be completely filled with fluid, the head of the patient being held in a suitable position, so as to produce the effect of a genuine ear bath of from two to ten minutes' duration. The pinna and the skin in the neighbourhood should be coated with vaselin (Lermoyez), in order to do away with the black stain which the light would otherwise produce in the deposit formed by the reduced silver.

The modifying substance employed for instillation in the ear are without number, those most frequently resorted to being alum (2½ per cent.), zinc sulphate (1 per cent.), aluminum aceto-tartrate (1 per cent.), carbolic acid (3½ per cent.), phenosalyl (10 per cent.). As vehicles are used water, glycerin, oil of vaselin, or alcohol, the last of which possesses modifying properties of its own which have suggested the use of pure alcohol for this purpose. In a recent article Dr. Couetoux has discussed certain details of alcohol dressing, showing that it exerts its action less on the tympanum than on the auditory meatus, the inflammatory swelling of which it rapidly reduces. Moreover, the susceptibility of the meatus, and not that of the tympanum, prevents employing alcohol of greater strength than 95 degrees, which Dr. Couetoux recommends for use in all dressings of the ears. He also calls attention to the fact that heat is an indispensable factor for the auditory meatus to be able to bear alcohol dressings, and he therefore advises in such cases

invariably to warm, not only the fluid, but also the ear of the patient.

Whatever their effect on the diffuse lesions of the mucous membrane may be, these instillations are powerless when it is necessary to destroy granulations or polypi, which frequently form in the tympanum in the course of an old-standing otorrhœa. Though alcohol, as Politzer claims, sometimes gets the better of granulations of small size, its action is so slow as to necessitate in most cases the use of more active substances, such as a bulb of silver nitrate or chromic acid at the tip of a probe, iron perchloride in its natural state, liquid, or crystalline trichloroacetic acid, and, in the tuberculous form of the disease (from 10 to 50 per cent.) or pure lactic acid. Any of these caustics destroys in a comparatively short time the granulations in question, but nothing equals the prompt and efficacious results of applying the galvanocautery, or, if the polypus is accessible, removing it by dividing the pedicle with Wilde's polypus snare or Politzer's cutting ring. When the tumour is sessile, it should be removed by abrasion with a curette. To complete the exeresis and prevent the reproduction of the tumours, it is usually advisable after the operation to cauterise the stump, but in spite of this precaution, recurrences not infrequently take place.

Surgical Treatment of Otorrhœa with Osseous Lesions.—Should the foregoing measures, in spite of having been systematically employed for a sufficient time, fail to afford relief, it is useless to continue a treatment which has proved its inefficiency, and recourse should therefore be had without delay to surgical measures. It is of the greatest importance, however, to be able to determine as far as possible the opportune moment when the treatment of otorrhœa should cease to be medical and become operative. The line of demarcation is indeed very faint, and the modern tendency toward operation at all hazards has made it still more uncertain. Taking everything into consideration, however, I think surgical intervention is indicated.

1. In all cases of old-standing otorrhœa, in which no improvement has been obtained by antiseptic treatment.

2. When the probe reveals the existence of osseous lesions, denuded spots or sequestra, either in the walls of the tympanum or the auditory ossicles.

3. When a cholesteatoma is detected or suspected.

4. When hearing is completely lost, so that no further damage can be wrought in this direction, the object of operation under such circumstances being to stop persistent suppuration, as in any other bony region.

5. Lastly, when there is the slightest symptom pointing to encephalic complication, intervention is not only justifiable, but imperatively called for.

It is not enough, however, to know when, but also how, to intervene. The methods employed in operations on this region are so numerous as to render a choice between them extremely embarrassing. Theoretically the operation must be adapted to the existing lesions, and should proceed according to a plan, carefully made up beforehand on the basis of the diagnosis. If the malleus or incus is necrosed, the diseased bone should be extirpated; if there is caries of the walls of the tympanum, they should be curetted; if mastoid lesions exist, trephining should be resorted to; if all the cavities are involved, they should be freely opened, &c. All this is very good, were it always possible to determine beforehand what particular anatomical lesions will be found in a given case of otorrhœa, but nothing is more uncertain, and one must always expect surprises in operations on the ear.

In the absence of precise data to go by, otologists have therefore lately in the treatment of otorrhœa followed a sort of scale, made up of a series of operations of increasing importance and gravity, from which a choice is made according to the persistence of the affection and the nature of the unsuccessful measures previously employed.

As a rule, the first measure resorted to is removal of the auditory ossicles, as soon as caries is suspected. This operation is not a difficult one, when performed through the auditory meatus (Poltzer, Miot), nor does it imply

any great risk, as hearing is usually completely lost previous to the intervention.

When this first attempt remains without result, another step is taken, and the walls are broken down, the anterior wall of the attic being almost invariably the first point of attack. Stacke has recently made a great improvement upon the old method of performing this operation. Instead of proceeding through the auditory meatus, he detaches it, together with the pinna, by a retro-audicular incision, thus reaching to the external wall of the attic, which he removes with a gouge or chisel, while a special "protector," introduced into the attic, prevents all danger of damaging the fenestra ovalis, promontory, or facial nerve by slipping of the instrument.

When the manner of making this large opening through the bony substance had been discovered, it became much easier than it had ever been before to observe what was going on in the cavities of the ear. It was thus unexpectedly found that the lesions of chronic otitis are much more extensive than had hitherto been supposed, the lesions of the bone involving not only the attic, but also the aditus and antrum. If these lesions were followed up by opening the external wall of the petro-mastoid canal, they led in the great majority of cases into the antrum, and thence into the mastoid cells. Stacke himself, for instance, could only in 2 out of 33 operations of this kind, limit his intervention to the attic, being obliged in the other 31 cases to gradually proceed as far as the mastoid process. Simply opening the attic, which was the first step aimed at, is therefore, as a rule, merely a preliminary step to the subsequent operation.

Under such circumstances it may be pertinently asked why, if one is almost certain in commencing with the tympanum to be obliged to continue until the deep strata of the mastoid process are reached, the start should not be made in the latter region and the antrum, which is very likely to be diseased, directly attacked, following the lesions, if need be, back to the tympanum? Such is, in short, the principle of the radical intervention, advocated by Schwartze, Küster, Zaufa, Luc, and Holmes, which appears destined to become the method *par excellence* of treating otorrhœa in the future. While Stacke in reality attacks merely the tympanic cavity, proceeding as far as the mastoid process only in a case of absolute necessity, the object of the method described by Luc, in 1894, under the name of "free opening of the cavities of the middle ear," is to penetrate at once into the antrum, excise the wall of the aditus, and finally reach the attic from the outside, everything being laid open, because it is known beforehand that all the parts are diseased. It is needless for me to call attention to the greater precision and efficacy of an operation which starts ahead of the lesions and follows them up to their source, or to the superiority, from a surgical point of view, of an intervention in which the operator knows beforehand where he is going, over one in which he starts from the tympanum, without being able to tell where he is going to stop.

THE HYSSOP:

ITS BOTANICAL HISTORY; ITS SYM-
BOLISM; ITS TOXICOLOGY AND ITS
THERAPEUTICS.

By JOHN KNOTT, M.A., M.D.,

CH.B., AND DIP. STAT. MED. (UNIV. DUB.);
M.R.C.P.I.; M.R.I.A.

(Concluded from page 5.)

The more practical "Herbal" of William Salmon gives the following account of the same plant:—

"Of Hyssop Common.

"I. The Names.—It is called in Arabick, Cyfe, Javes, Jufa, in Greek, *ῥύσσωπος*, in Latin, *Hyssopus*, in English, *Hyssop*.

"II. The Kinds.—There are two principal Kinds hereof, viz., 1. *ῥύσσωπος κοινός*, *ῥύσσωπος ὑψηλός*, *Hyssopus Vulgaris*, Our Common Hyssop. 2. *ῥύσσωπος ἁγίος*, *Hyssopus*

infrequens, *Hyssopus incelebris*, vel *insolitus*, *Hyssop* Strange, and not *Vulgar* or *Common*, of which in the next Chapter.

"III. The Kinds.—Of Our Common Garden *Hyssop* there are only two Kinds, viz., 1. *Hyssopus Vulgaris*, *Hyssopus Arabum*, Our *Vulgar* or *Ordinary Hyssop*. This *Hyssop* is not the *Hyssop* of *Dioscorides* and other Greek Authors, as all our modern Botanists do acknowledge, except *Matthioli*, who earnestly contends that Our Garden *Hyssop* is it, against all reason; nor do any of our Herbarists know (as far as I can find) what the true *Hyssop* of the Greeks was. As for Our Common Garden *Hyssop*, it is certainly the true *Hyssop* of the Arabians, and so we take it. 2. *Hyssopus Arabum Floribus rubris vel albis*, *White* or *Red Flowered Hyssop*.

"VI. The Descriptions.—The first, or the *Vulgar Ordinary Hyssop*, has a Root which is somewhat woody, with many thready strings thereat; it is a small bushy Plant, which rises up with many woody but tender Branches, something more than a Foot high, on the Stalks and Branches whereof are set at certain distances several small, narrow, and long green Leaves not dented at all on the edges; at the tops of the Stalks and Branches grow bluish purple gaping Flowers in spiked Heads, one row above another, after which follows the Seed, which is small and blackish; the whole Plant is of a vigorous or strong, sweet, pleasant smell.

V. The second, or *White* or *Red Flowered Hyssop* They have a Root like the former, but are scarcely to be distinguished in their form and manner of growing from the Common Garden Kind (of which this is a sort) the chief difference is, that they do both usually bear white or red Flowers, all on one side of the Spike, yet continue not constant in that form, but change into the form of the former Common Kind, and so become (as it were) the same Plant, and after that change not to be discerned therefrom

"VI. The Places.—They grow with us only in Gardens, and that through the whole Kingdom of England and Ireland, but they grow wild in Arabia, and other hot Countries, as also on the Hills of Romania, about Verona, and near unto Mount Baldus.

"VII. The Times.—They Flower in the Summer Months, viz., in June and July, and their seed is ripe in he beginning or middle of August.

"VIII. It is hot and dry in the third degree, *Aperitive*, *Absterive*, *Astringent*, *Anodyn*, *Carminative*, *Digestive*, *Diuretick*, it incides, rarifies, and makes thin; it is *Stomackick*, *Pectoral*, *Cordial*, *Splenetick*, *Nephritick*, and *Arthritick*, *Emmenagogick*, *Alexipharmick*, and *Analeptick*.

"IX. The Specification.—It is peculiar against *Asthma's*, *Coughs*, *Colds*, *Catarrhs*, *Wheezing*, *Shortness of Breath*, difficulty of breathing, cures *Consumptions*, *Strangury*, *Falling Sickness*, and *Green Wounds*.

"X. The Preparations.—You may prepare therefrom 1. A Liquid Juice. 2. An Essence. 3. A Decoction in Wine or Water. 4. A Lohoch or Syrup. 5. A Powder. 6. Pills. 7. A Lotion or Gargarism. 8. An Oil by Decoction. 9. A Ba'sam or Ointment. 10. A Cataplasim. 11. A Distilled Water. 12. A Spirituous Tincture. 13. An Acid Tincture. 14. An Oily Tincture. 15. A Saline Tincture. 16. A Spirit. 17. An Oil Distilled. 18. Powers. 19. An Elixir. 20. A fixed and Volatile Salt. 21. A Wine.

THE VIRTUES.

"XI. The Liquid Juice.—Mixed with Honey and taken it kills Worms in the Belly, and helps *Asthma's*, *Coughs*, *Colds*, *Wheezing*, *Shortness of Breath* and other Distempers of the Lungs, caused by a plenitude of Humors. Dose from one spoonful to three, Morning and Night.

"XII. The Essence.—It has all the Virtues of the Juice, besides which it is excellent against the *Falling-Sickness*, *Agues*, *Catarrhs*, or *Distillations of Rheum* upon the Lungs, and other parts; it amends and cherishes the Native Heat, and color of the Body, &c., and is a powerful Remedy against the *Colick*, *Strangury*, obstruction of the Terms in Women, *Poyson*, the bitings of mad Dogs, Serpents, and other Venomous Creatures; it cuts tough Flegm, and causes expectoration. Dose

two or three Spoonfuls in the Distilled Water, or some other proper Vehicle.

"XIII. The Decoction in Wine or Water.—It has all the Virtues of the Juice and Essence, but nothing near so powerful, and therefore may be given Morning, Noon, and Night to six or eight Ounces, sweetened with new Honey; if Rue and Honey is boiled with it, and so drunk, it stops *Catarrhs* upon the Lungs, and has the other Virtues of the Juice and Essence; if the Decoction, Juice, or Essence, is mixed with *Oxymel* it purges gross Humors by Stool, and kills Worms in Children; if any of these three Preparations are mixed with pulp of Figs and Sal Nitre it loosens the Belly and works downwards also; if either of them are mixed with Juice of Garden Cress and Blew Flower de luce Roots, or powder of the said Flower de luce Roots, in a fit proportion, this mixture will purge the Bowels yet more forcibly, carry off the causes of the *Colick*, cure the *Yellow Jaundice*, *Dropsie*, *Obstructions of Liver*, *Spleen*, and *Womb*, and restore the true Color of the Skin, this more especially if it is taken twice or thrice a week, as the body can bear it.

"XIV. The Lohoch or Syrup.—Take of the clarified Juice two Pounds, of choice Honey four Pounds, mix, and boil to the consistence of a Rob or Quiddony. It has the Virtues of the Juice, Essence, and Decoction, and may be taken three, four, five, or six times a day, or more, as the nature and reason of the Disease requires; it causes an admirable expectoration of the morbid matter out of the Bronchia of the Lungs; takes a little of it at a time with a small little Spoon, and let it distil down the Throat gradually.

"XV. The Powder.—It is made of the Leaves, Heads, and Flowers; strewed upon Green Wounds, it presently heals them, upon old running Ulcers it cleanses, dries and heals them also; applied with powder of Cumin Seed, Salt, and Honey, it is good against the bitings of Vipers, Rattle-Snakes, Mad Dogs, and other venomous Creatures; given inwardly to one Dram, or Dram and half, it gives ease in the *Colick*, provokes the Terms, and opens the obstructions of the Urinary parts; it causes to break wind, and prevails against cold fits of Agues.

"The Pills.—Take *Hyssop* in Powder, Male Peony Roots in powder, of each two Drams, Castoreum in powder one Dram, Horehound in powder, *Assafoetida*, of each half a Dram, Crystals of Luna in powder a Scruple, with Rob of *Hyssop* (made *per se* without Honey), q.s. mix, and make a mass of Pills, for seven Doses, to be given every night at Bed time: This is said to be a specific and effectual Remedy against the *Falling-Sickness*, to be repeated every New and Full Moon so long till the Cure is completed: These Pills cure also a vehement Headache, tho' of very long standing, and are prevalent against a Vertigo.

"XVII. The Lotion or Gargarism.—Take *Hyssop* four good handfuls, White or Red Port Wine three Pints, Sal Nitre an Ounce, mix, and boil for a quarter of an hour, then drain off the clear. It is a singular good thing against the Quinsie, or any soreness of Throat or Mouth, it abates the inflammation of the Throat, and discusses the swelling thereof, being often gargled therewith; it takes away inflammations in other parts of the Body, as also black and blew spots and marks, which are occasioned by Falls, Blows, or Bruises; if Wine Vinegar is used to make the Lotion with instead of the Wine, it will cure the Toothache, and the fumes thereof being received thro' a Funnel into the Ears eases their pains, and abates an inflammation if any is present, and also takes away their singing noise.

XVIII The Oily Decoction or Insolation.—Being anointed upon the Head it is said to kill Lice and Nits therein, and take away the itching: taken inwardly to one or two ounces mixed with Honey it opens obstructions of Stomach and Lungs, and causes the pituitous matter to pass off through the Guts; anointed upon any part swollen and pained thro' cold, it eases the pain and discusses the swelling.

"XIX. The Balam or Ointment.—Being applied they quickly heal any Simple or Green Wound in the Hand, or other parts of the Body; applied also to old running Sores and foul Ulcers they cleanse, dry, and heal them quickly, more especially if the Powder of the Herb

afore named be also strewed upon the same; the Balsam applied upon any part pain'd with the Gout gives ease in the pain, and by continuing the application in a short time cures it.

XXI. *The Cataplasm.*—Made of the Green Herb by bruising, adding also thereto Sugar and Salt, with a few Crumbs of White Bread, and applied, it is admirable to discuss any recent simple contusion, or heal any simple Green Wound, in what part of the Body soever.

XXI. *The Distilled Water.*—It has the virtues of the Juice, Essence, and Decoction, sweetened with Sugar or Honey, and so taken from two ounces to four ounces, but it is mostly used as a Vehicle to convey the other Preparations down in; outwardly used sweetened with Honey it is of good use to cure sore and running eyes.

XXII. *The Spirituous Tincture.*—It is Cephalick, Neurotick, Stomatick, and Pectoral, it is good against Wind in the Stomach, gives ease in the Colick and gripings of the Guts, and sweetened with Honey it eases the vehemency of the Cough, and causes Expectoration; it is good against Vapors from the Womb, Fits of the Mother, and the Falling-Sickness. Dose one Spoonful in the Morning fasting, another an Hour before Dinner, and the like at Night going to Bed, in the Distilled Water.

XXIII. *The Acid Tincture.*—It is good against the Plague, and all sorts of malign and pestilential Diseases, it resists Poyson, and is efficacious against the bitings of mad Dogs, Vipers, and all other kinds of Venemous Creatures; it cleanses the Stomach, strengthens it, and causes a good Appetite and Digestion, suppresses Vapors, and resists Hysterick Fits; it powerfully opens obstructions, and attenuates thick and poor Humors which clog and stuff the Viscera, causing the same to be carried off by Stool and Urine. Dose so many drops as to make the Vehicle pleasantly sharp.

XXIV. *The Oily Tincture.*—It opens the obstructions of the Urinary parts, as also of the Womb, provokes Urine and the Terms, expels Wind powerfully, and gives ease in the Colick, gripings of the Guts, Stone, Gravel, Strangury, &c. Dose from ten to twenty drops in any proper Vehicle Morning and Night; it gives ease in the vehement pains of the Back, and outwardly used is food against Convulsions, Cramps in any particular part of the Body, as also the Palsie and Gout, &c.

XXV. *The Saline Tincture.*—Inwardly taken in a Glass of White Port Wine from half a Dram to a Dram, or Dram and half, it is prevalent against the Strangury, and causes a Pissing freely; outwardly used it is food against Scabs, Pimples, breakings out, Tettars, Ringworms, Scurf, Morpew; Tanning of the Skin, sunburning, Yellowness, and other deformities thereof, the Skin (after being first wash'd clean with warm Water) being well bathed therewith Morning, Noon, and Night.

XXVI. *The Spirit.*—Being dulcified with double refined Sugar it is a most excellent Stomatick and Cordial, it expels Wind, gives ease in the Colick and gripings of the Guts, it prevails against Fainting and swooning Fits, Sickness at Heart, and other Distempers of the Stomach and Præcordia. Dose from half to one Spoonful in Canary, or some other Wine or proper Vehicle.

XXVII. *The Distilled Oils.*—It is a specifick against an old inveterate Cough, Catarrh, and Asthma, it cures the Colick to a Miracle, expels Wind powerfully, and cures Convulsions, Lethargies, Vertigo, and the Palsie after a singular manner; it admirably strengthens the Nerves and Brain, and is good against all cold and moist Diseases affecting these parts, let them come from what cause soever; it eases the Headach coming by reason of cold, and is a singular Antidote against the Gout, being both inwardly taken and outwardly applied; it is powerful against Agues, as also against the Headach, Megrim, Vertigo, Carus, Lethargy, and other Diseases proceeding from cold and moisture, but more especially it is said to be a peculiar remedy for the Falling Sickness, tho' in Persons past their Minority, and who are advancing towards their middle Age; in the Palsie the Back Bone is to be Anointed these, with Morning and Night, rubbing it well in, and inwardly it is to be given from four drops to ten, fifteen, or twenty, according as the Patient is in Age and Strength,

and the Dose to be repeated Morning and Evening so long as need requires; let it be dropp'd into White Sugar, with which it is to be well mixed, then add to it the Vehicle you design to give it in, and so let the Patient drink it.

XXVIII. *The Potestates or Powers.*—They have also the Virtues of the Distilled Oil, and are much more thin and penetrating, sinking into the Flesh as fast as they are put on; they are to be outwardly used in the same manner as the Oil, and to the same parts in the same cases, and likewise to be inwardly given Morning, Noon, and Night, from thirty to eighty or an hundred drops, in a Glass of Wine, or other proper vehicle.

XXIX. *The Elixir.*—The Virtues hereof are just the same with the Distilled Oil and Powders, and to be used also outwardly and inwardly in the same manner, saving that the Dose of the Elixir is only from twenty to sixty in Wine, or some fit Vehicle; given in sherry or Madeira Wine to sixty drops or more in Pleurisie it gives present ease, and in a little time after a perfect cure; in particular also it is a very excellent thing to kill worms in children.

XXX. *The Salt Fixed and Volatile.*—They are both Alcalies, and so absorb acids, infallibly cure the pain of the Stomach, tho' inveterate and never so vehement, they have been given with good success in all sorts of Colicks, they open obstructions of all the Viscera, but more particularly of the Spleen, Reins, and Womb; they suppress Vapors, prevail against Hysterick Fits, conquer Hypochondriack Malancholly, deobstruct the Urinary passage, and give present ease in the Strangury, causing the Patient to piss plentifully and easily, and being continued for some convenient time cure the Yellow Jaundice. Dose, from ten to twenty grains, or more, in a Glass of generous White Port Wine Morning and Night, or often, in the daytime if need so require.

XXX. *The Wine.*—Take Hyssop chopped small a handful, choice ripe Figs slit three ounces, White Sugar candy an ounce and half, Muscadine a Quart; boil together till half a pint is consumed, then strain out and keep it for use. Dose, three spoonfuls Morning and Evening against an old Cough; it causes the tough Flegm to be more easily expectorated, gives ease to the Strangury by opening the passages of the Urine when they are stopped; and provokes the Terms in Women when preternaturally stopped.

And even the various kinds of wild Hyssop had, in addition to the common family virtues, special praiseworthy medicinal qualities, each after its kind. It now looks strange that a plant which enjoyed so high a reputation in past ages could have dropped below the range of therapeutic vision as to be seldom heard of, except on an occasion like the one referred to in the opening paragraph of this paper, when its use only afforded the most disastrous results. It is somewhat better known, however, on the Continent. Baillon (*Botanique Médicale*) tells us that: "Ses feuilles et ses sommités fleuries, très odorantes, sont employées comme stimulantes, pectorales, sudorifiques et détersives; on les adjoint à certains mélanges purgatifs pour leur donner de l'arome. C'est un condiment pour quelques personnes." And this illustrious medical botanist goes on to inform his readers that "L'idée que cette plante est purifiante repose sur ce fait que ses branches rameuses servaient de goupillons pour répandre les eaux lustrales."

The application of the leaves and tops of this plant to the sprinkling with lustral and consecrated waters in religious rites has been brought down with Christianity on account of its prominent Scriptural celebrity. Yet the identification of the *Hyssopus officinalis* with the terms rendered "hyssop" in the various texts of Holy Writ is based upon opinion which requires corroboration. So that it may some day be demonstrated that the whole reputation of Hyssop originated in what is known to logicians as a "fallacy of equivocation." The sprinkling with "a bunch of hyssop" commanded by the law of Moses; its intimate association with the sacred cedar-wood and scarlet in the Jewish ceremonies; the Biblical testimony that it elicited the special comment of King Solomon in the flower of his might and his wisdom; the piteous appeal of the penitent David in his affliction, "purge me with hyssop and I shall be clean"; the

incident on Mount Calvary when "they filled a sponge with vinegar and put it upon hyssop"; the thesis defended by some mediæval theologians that the "*Crown of thorns*" was formed of the wild hyssop; and the fact that mediæval astrologers placed the hyssop under the special guardianship of Jupiter—all combined to throw a glamour around its name. In the present state of knowledge we can only say of hyssop that its identification with the plant so named in our translations of the Bible is, to say the least, doubtful; that its medicinal advantages are questionable, and can be more reliably obtained from other sources; while its mischievous effects have been satisfactorily demonstrated.

Clinical Records.

WESTMINSTER HOSPITAL.

Case of Hepatic Multilobular Cirrhosis.

Under the care of Dr. MURRELL.

W. P., æt. 43, was brought to the hospital on November 13th, 1899, with a history of having passed blood with his motions. It was noticed that he was slightly jaundiced, and on a cursory examination it was found that his liver extended about two inches below the umbilicus. Soon after admission he passed two motions consisting of a little light-coloured fæces mixed with about a pint of bright-red blood. It was thought that he might have cancer of the liver, secondary to a malignant growth in the rectum. A rectal examination was made under an anæsthetic, and a mass of internal piles was detected, but nothing presenting the signs of a malignant growth. The prostate was enlarged, and the question of that being the primary seat of the disease was discussed. This view was negatived on the ground that cancer of the prostate is a disease of late life. A more careful examination was then made of the liver, and it was found that it was uniformly enlarged and that no nodules could be detected. The diagnosis of hypertrophic cirrhosis was then definitely made. The patient at first denied any alcoholic history, pointing out that he had held a responsible position for many years, and urging that if he had been addicted to drink his services would not have been retained. Later on he admitted that he had been in the habit of taking a good deal of beer varied with rum when the day happened to be cold or damp. He had had three attacks of gout, but stated that he had not suffered from syphilis. It was quite clear that he was perfectly well up to four months before admission, when he first noticed blood in the motions. He had continued in active employment until within seven weeks of admission. His temperature was always above normal, varying from 99.6 in the morning to 102.8 in the evening. The urine had a sp. gr. of 1025, and contained bile pigments. The hæmorrhage from the bowels was checked by rectal injection of liquor hamamelidis. He was ordered large doses of iodide of potassium with inunctions of calomel ointment night and morning. His liver rapidly decreased in size until the lower edge was well above the umbilicus. This was followed by ascites, and the patient rapidly passed into an apathetic condition with increased jaundice. He died on December 14th after an illness of about five months' duration.

At the post-mortem examination (made by Dr. Lazarus Barlow) the liver was found to weigh 4 lbs., 11 ozs. It was wrinkled on the surface and tough on section. The colour was not yellow as is ordinary with cirrhosis, but slaty. On microscopical examination it was found to be a very fine framed variety of multilobular cirrhosis. The gall-bladder was dilated and pressure failed to expel any bile out of the duodenum. The common bile duct, when slit up was found to be contracted, but appeared normal. The spleen weighed 9 ozs., was firm and of a brightish red colour; capsule thickened. The kidneys were normal, except that the left was provided with two ureters. The cæcum (filled with gas) was dilated into a pouch 8 ins. long and 8 ins. or more in circumference.

Transactions of Societies.

OBSTETRICAL SOCIETY OF LONDON

MEETING HELD WEDNESDAY, JANUARY 3RD, 1900.

MR. ALBAN DORAN, F.R.C.S., President, in the Chair.

CAST OF THE UTERUS OF PROBABLE INFLAMMATORY ORIGIN.

DR. T. W. EDEN showed a cast of the uterus passed by a patient, who had been confined eighteen months previously. She had no dysmenorrhœa; she usually menstruated about every six weeks, and the cast shown had been passed after forty-eight days' amenorrhœa. It was rather larger than would be the cast from a normal-sized uterus. It showed evidence of endometritis, and was probably of inflammatory origin; microscopically there was neither epithelium nor glandular tissue, but there were numerous leucocytes. It showed a few cells like decidual cells; it had been shown that the presence of such cells in the endometrium was characteristic of a former but not necessarily recent pregnancy.

THE PRESIDENT pointed out that on such a specimen important medico-legal questions might depend, especially with regard to its significance as indicative of pregnancy. Mr. Taylor, of Birmingham, and others had shown that there was no true distinction to be drawn between the cast from a case of membranous dysmenorrhœa and one from a case of extra-uterine gestation.

DR. C. HUBERT ROBERTS asked whether Dr. Eden drew any distinction between a case of this kind and one of membranous dysmenorrhœa. On the latter subject there was still much confusion, but the condition might perhaps be regarded as inflammatory. This view was taken by several authorities.

MR. TARGETT agreed with Dr. Eden that the main characteristics of this specimen were those of inflammation; but it might do quite well for an example of membranous dysmenorrhœa. The mere presence of decidual cells did not point to much one way or the other. He thought that Mr. Taylor went too far in saying that the casts of membranous dysmenorrhœa and extra-uterine gestation were indistinguishable; his own view was that in the majority of cases the difference between the two could be made out.

DR. EDEN, in reply, agreed with Mr. Targett that the cast of ectopic gestation could be distinguished from that of membranous dysmenorrhœa. The specimen differed from the latter condition in two points; first, the patient had no dysmenorrhœa; and secondly the cast was extruded whole, whereas in membranous dysmenorrhœa the membrane usually came away in shreds.

ECTOPIC GESTATION: MACERATED FŒTUS REMOVED TWO MONTHS AFTER TERM.

THE PRESIDENT showed this specimen, removed two months after a spurious labour. The gestation sac was formed mainly by the posterior layer of the left broad ligament; and the pregnancy was the type recently described by Mr. Taylor as "posterior ligamentary" or retroperitoneal. A fæcal fistula complicated the convalescence; but the patient recovered.

DR. CULLINGWORTH said that he had reported two or three cases of this kind. Circumstances were often unfavourable to the recovery of these patients, and Mr. Doran was, therefore, to be congratulated on his success. In one of his own cases there were three distinct communications between the sac and the bowel, and the patient lived only three days after operation. He would ask why in Mr. Doran's case the placenta was not removed at the time of operation? When the fœtus had been dead some time, the removal of the placenta was usually easy, and unattended by important hæmorrhage, as he found in one of his cases operated on four weeks after the death of the child.

DR. JOHN PHILLIPS had operated on two such cases, and had another under observation, whose conception dated twelve months back. In both his operations he removed the placenta without difficulty, and he believed

that this was the general experience in cases dealt with three or four months after the spurious labour. Both his patients recovered.

Dr. HANDFIELD-JONES had also had two cases. One was a macerated foetus; he did not remove the placenta, but stitched the edges of the sac to the wound. She did well. In the other case the child was living. He dealt with the sac in the same way, but she died of sepsis two weeks later. At the autopsy it was found that the placenta was intimately attached to the iliac vein; any attempt to remove it at the time of operation would probably have resulted in death from hæmorrhage from rupture of the vein. No hard and fast rules could therefore be made on the mode of dealing with the placenta.

The PRESIDENT, in replying, added that the sac was a distinct one, whose edges could be secured to the wound. It was not, therefore, one of those spurious sacs formed by adhesions, such as occurred in a case of primary abdominal pregnancy. They owed the differentiation of anterior and posterior ligamentary pregnancy to Taylor. The cases where the sac contents were fetid seemed to be always those of posterior ligamentary pregnancy; in the other type the tendency was rather to the formation of a lithopædion. In reply to Dr. Cullingworth, he could not remove the placenta, because, owing to its extensive attachment, removal would have involved the dissecting up of the whole rectum.

FOUR CASES OF RUPTURE OF THE UTERUS.

Dr. H. SPENCER read notes of four cases of rupture of the uterus successfully treated by packing the tear *per vaginam* with iodoform gauze. They are the only cases in which he has adopted this method of treatment, and the only cases which he has known recover. All the others (about eight in number) have died in a few hours from shock and hæmorrhage or in a few days from sepsis. Twice he has performed abdominal hysterectomy with a fatal result. After quoting some remarks he made in the "Obstetrical Transactions" for 1897 upon the great danger of the operation of abdominal hysterectomy in patients shocked by rupture of the uterus, the author expresses the belief that the mortality of rupture of the uterus may be lessened by the use of gauze packing. Having alluded to the advocacy of gauze packing by others, he expresses his own views, for the purpose of discussion, as follows: In the treatment of rupture of the uterus—(1) *Abdominal section* is rarely required, and almost solely in cases where the foetus has passed completely or in great part into the peritoneal cavity. It should be performed rapidly under local infiltration anaesthesia, and should be followed by flushing of the peritoneal cavity, with normal salt solution and by suture of the tear if possible, or, if this be not possible, by packing the tear with iodoform gauze and draining by the vagina or abdomen. (2) *Abdominal hysterectomy* is hardly ever necessary; when the broad ligaments are so much damaged as to endanger the vitality of the uterus vaginal hysterectomy should be performed. (3) All incomplete tears implicating the broad ligament and most complete tears should be treated by packing the rupture *per vaginam* with iodoform gauze after removing clots and fluid blood.

The PRESIDENT drew attention to the fact that when using iodoform gauze absorption of iodoform might lead to a very rapid pulse, which might be confusing as leading to a suspicion of sepsis. This might occur also after ovariectomy when iodoform gauze drainage was used.

Dr. HORROCKS considered that cases of rupture confined to the cervix and broad ligament were much less serious than those opening into the peritoneal cavity. He had met with a fair number of cases of rupture of the uterus: one was a tear from the cervix into the peritoneal cavity, the result of precipitate labour; he put in two stitches and packed with sal alembroth gauze, which was renewed under an anaesthetic every twelve hours for three days, then once a day. Two other cases were treated successfully by packing. In a fourth case the rupture resulted from an attempt to remove a piece of placenta, and was situated in the anterior uterine wall. He opened the abdomen and stitched the tear. The patient recovered, although the wound broke down

on the tenth day from a fit of coughing. In an aseptic case he could see no objection to sewing up the wound; but he did not think that hysterectomy was advisable in any case. Would Dr. Spencer insist on the use of iodoform gauze? It seemed to him that sterilised gauze would answer equally well.

Dr. LEWERS recounted a case of rupture of the uterus in which the tear extended through the posterior wall into the peritoneum. The rent was packed with iodoform gauze, and though the condition was very critical for ten days, the patient recovered. He had used iodoform gauze in many abdominal sections, and had seen cases with rapid pulse from absorption. He believed that this was due to a larger percentage of iodoform in some samples of gauze. He had found carbolic gauze answer just as well.

Dr. HANDFIELD-JONES considered that much depended on whether the rupture was complete or incomplete. A list of 13 cases had recently been reported from Vienna, and they were all treated by packing with iodoform gauze; eight were complete, and the patients all died; the remaining five were incomplete, and all recovered. Lateral tears into the broad ligament generally recovered, whether treated by packing or by simple antiseptic douching; he had seen three cases of this kind and they all got well. He had had two cases of complete rupture; in one the child was found lying among the intestines; the rent had then so shrunk up that it was difficult to realise that the child had passed through it. In the other case the rent was through the fundus, and the peritoneal cavity was filled with meconium. Both cases were treated by abdominal section, but neither recovered.

Dr. HERMAN advocated gauze packing for most cases, but if the packing could not be passed right up to the top of the rent, through the vagina, then the uterus should be removed through the vagina. Dr. Spencer had given them a useful hint in advocating the passage of a large tube through the rent in order to evacuate the blood from the peritoneal cavity.

Dr. DRUMMOND ROBINSON had had three cases: two of these he packed, but one succumbed to shock; the other recovered and had since become pregnant again and had a normal confinement. In the third case the rupture was incomplete, extending into the left broad ligament; he had no gauze with him when he first saw the patient, and he left her, intending to pack the rent the next day. But at his next visit she was so much better that he did not use the gauze, and she recovered satisfactorily.

Dr. SPENCER, in the course of his reply said that he believed that the majority of the fatal cases were those of the incomplete type, i.e., into the broad ligament. Four of his eight fatal cases were of this kind. He did not approve of repacking every twelve hours under an anaesthetic; if gauze were used at all, it should be left in for three or even six days. He did not think aseptic gauze would be so good as iodoform gauze, for it would not be likely to remain sweet.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

MEETING HELD FRIDAY, JANUARY 5TH, 1900.

Dr. J. B. BALL, the President, in the Chair.

Mr. PERCY DUNN, in a feeling and appreciative speech, proposed a vote of condolence and sympathy with the family of the late Sir James Paget, an honorary member of the Society. The proposal was seconded by Mr. SWINFORD EDWARDS and carried unanimously.

The SECRETARY read the report of the committee appointed at the ordinary meeting on December 1st, to organise a scheme for gratuitous attendance on distressed families of soldiers. The Committee reported that 203 members of the Society had written offering to co-operate in the scheme. Of these replies 44 were from consulting physicians and surgeons and from men practising in various special departments. The remaining 159 were from men in general practice.

Mr. L. A. BIDWELL then read his paper on

SURGICAL TREATMENT OF DILATED STOMACH.

The principal causes of dilated stomach were:—(1) cicatricial contraction of the pylorus, (2) malignant disease, (3) adhesions outside the pylorus, (4) gastroparesis, (5) spasm of pylorus, (6) floating kidney on the right side, (7) atony. Only the first three of these various conditions were discussed at length by the author. With regard to diagnosis, the following principal methods of examining the stomach was advocated: (1) inspection, (2) palpation, (3) percussion, (4) auscultation, (5) intubation, (6) artificial distension of the stomach with gas, (7) chemical examination of the stomach contents. The indications for operation on the dilated stomach were:—(1) pain usually localised to the pyloric region and felt in the back, (2) signs of dilatation of the stomach, (3) vomiting of solid food, (4) absence of free hydrochloric acid from the vomit, (5) some emaciation, (6) obstinate constipation. The surgical procedures which were undertaken for the relief of dilated stomach were, in malignant disease:—(1) pylorotomy, (2) gastroenterostomy. In non-malignant stenosis: (1) pyloroplasty, (2) gastroenterostomy, (3) Loretta's operation; (4) pylorotomy; (5) division of adhesions. And in neurotic cases: (1) lavage, (2) massage, (3) gastropexy, (4) an operation for diminishing the capacity of the stomach by folding in a portion of the redundant wall. The paper was illustrated by sixteen cases operated on by the author, and arranged in tabular form. Eleven were cases of malignant disease, five of these died within a fortnight, the remainder living some months. There were five cases of non-malignant stricture which were all cured by operation. Of the malignant cases seven were gastroenterostomies with three deaths, three were pylorotomies with one death, one was a case of pyloroplasty and proved fatal.

Remarks were made by the President, Messrs. Swinford Edwards, C. B. Keetley, McAdam Eccles, and Dr. R. Bevan. Mr. L. A. Bidwell briefly replied.

BRADFORD MEDICO-CHIRURGICAL SOCIETY.

MEETING HELD DECEMBER 5TH, 1899.

The President, Mr. W. HORROCKS, F.R.C.S., in the Chair.

TUBERCULOSIS IN ITS RELATION TO PUBLIC HEALTH.

Dr. CROWLEY read a paper on the "Sanatorium Treatment of Phthisis." He laid stress on treatment in a sanatorium as distinguished from "fresh air" and other methods, in that it was a mental as well as a physical remedy; and he urged the importance of strict discipline in regulating and controlling every detail of the patient's life. Very satisfactory sanatoria could be made in most parts of the kingdom, provided that the air was pure and free from soot, the soil well drained, that the building was sheltered from the prevailing winds, and that there was a fair amount of sunshine. All cases were suitable for treatment, those in the early stages naturally yielding the most satisfactory results. A large proportion of cases were curable for the time being, the cure being maintained only if suitable habits of life were observed after the patient's return home. Finally, it was urged that the co-operation of the whole medical profession must be secured in order that sanatorium treatment should be a success.

Dr. ARNOLD EVANS read a paper on "Tuberculosis, its Prevalence and Prevention." The preventive measures recommended were:—(1) That persons suffering from phthisis be isolated in sanatoria, and their houses and furniture disinfected. That sputum and other discharges be not allowed to become dry, and so get diffused in the atmosphere. (2) That all dairies and cowsheds should be registered. That cows with indurated udders should be notified to the sanitary authority, and their milk not mixed with that of healthy cows. That the carcasses of slaughtered animals should be inspected by a competent person. That, till preventive measures were taken, all milk should be sterilised.

Dr. METCALFE urged the importance of early diagnosis, in order that treatment might be satisfactory.

Dr. MAJOR thought that public opinion was not yet ripe for compulsory notification, but suggested that some system of voluntary notification be adopted.

Dr. BELL said that the introduction of sanatoria was sure to be associated with a great deal of quackery. He threw doubt on the accuracy of statistics from institutions conducted for the profit of the superintendent. He advocated the compulsory notification of phthisis. He thought doctors would leave themselves nothing to do as general practitioners.

Dr. RABAGLIATI advocated the prevention of phthisis by inculcating into the minds of the public the importance of fresh air, exercise, and diet. He thought that public bodies might do much good by insisting that the living rooms of all new houses should have an adequate cubic space.

Dr. EURICH alluded to the prevalence of porcine tuberculosis, and remarked that the liver and tonsils were the organs chiefly affected.

Dr. P. LODGE congratulated the Society on its having two such representative papers of such far-reaching interest on the same occasion before them. He thought what was wanted was State sanatoria for the poor whose insanitary methods of living and state of knowledge particularly laid them at the mercy of this terrible scourge the tuberculous bacillus.

Drs. Goyder, S. Johnstone, and Horrocks also joined in the discussion, and Drs. Crowley and Evans replied.

EXTRA UTERINE PREGNANCY.

Dr. LEFAGE, in lecturing on the diagnosis of the above, said that several cases of pregnancy, in reality uterine, had been taken to his knowledge for extra-uterine pregnancy. The diagnosis of the latter presented, however, difficulties varying with the period of the gestation at which the woman is examined and the intensity of the incidents produced. For the last ten years the diagnosis was rendered more easy by a more accurate knowledge of the symptoms. Yet it was frequently possible to confound the situation of the foetus in both cases. A woman is seven months pregnant since her last monthly period; she has lost blood several times and complained of suffering in the abdomen, pain not felt in previous pregnancies. Sometimes a doctor or a midwife called towards the third month of gestation have declared imprudently that abortion was imminent, and even that it had already taken place. Besides the patient had suffered some difficulty in emptying the bladder and the rectum. In a word, in questioning the woman the more or less classical type of ectopic pregnancy presents itself to the mind. It is thus that a strong road is being taken and will be persisted in if obstetrical examination reveals some anomaly in the form or in the situation of the uterus.

STRICTURE OF THE PYLORUS.

Prof. Chénieux has published an interesting case of stricture of the pylorus, cured by operation. The case was that of a young woman suffering from grave disturbance of the gastric functions. Appetite was lost, but no matter what she ate the stomach permitted considerable distension and afterwards emptied itself by vomiting. Food did not pass through the pylorus; milk, although more tolerated, was not completely digested. The patient consequently became emaciated and lost strength rapidly. Her medical attendant sent

her to Vichy, but with little benefit, and finally concluded that the case was one of stricture of the pylorus, and advised an operation.

The woman was operated upon by Prof. Chénieux, who, after laying bare the stomach made an incision perpendicular to the ring of the pylorus of an inch-and-a-half long. He drew together the two extremities of the incision which became thus transversal and parallel to the pyloric ring and then sutured with fine silk. No liquid flowed into the abdomen, which was closed without drainage.

The result was most satisfactory. The patient one month after the operation was able to well digest her food, while her strength and embonpoint returned with surprising rapidity.

ZONA.

An alcoholic solution 1-10, of picric acid is strongly recommended by Prof. Thiery for the treatment of zona. Painted on with a brush the alcohol evaporates very rapidly leaving behind a layer of protection. The inflammatory phenomena quickly disappear with this dressing and pain is suppressed. The application of picric acid in this manner also facilitates a definite cure.

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, January 6th, 1900.

At the last meeting of the Society of Surgeons, Hr. Riese gave a contribution to the subject of

THE SURGERY OF THE SKULL.

He first showed a boy of ten who had been shot in the head, the bullet entering above the left orbit. The boy was brought in an hour after the accident, and at first had symptoms of general compression of the brain, with left-sided paralysis. The pressure symptoms gradually subsided, speech also returned, but the paralysis remained. The speaker believed that the internal capsule was injured.

A second case ran a similar course.

A third case was that of a girl of nineteen, who had the entrance opening below the right eye. There were no brain symptoms. The wound healed readily, but gradually headaches set in that reached such a high pitch that the girl, who had been discharged from hospital, was obliged to return. In the several Röntgen illuminations, the position of the bullet could only be seen from the side; according to these it appeared to be in the orbital fissure. The speaker then determined to search for the bullet, and began from the side, but it did not lie in the inferior orbital fissure, but in the superior, near the optic nerve and the motor oculi. It was removed, and the nerve, perhaps, bruised at the time but not torn; the ciliary ganglion was also touched, but was certainly not injured. In spite of this, separation of the retina took place. This became adherent again, but atrophy of the nerve had advanced.

In a fourth case a man had shot himself in the forehead whilst lying down. In the midst was a depression which, after healing of the wound, he treated by operation, removing some splinters and the bullet.

A weight fell on to the head of a child of four. A cephalæmatoma formed over both parietal bones, which as well as the unconsciousness increased. After five days the child ceased swallowing, left hemiplegia set in,

whilst twitchings took place on the right side. The symptoms of general compression gave way to local symptoms. The pulse was a good deal accelerated. The head was trephined both on the right and left side at the spot where the middle meningeal artery was generally sought for, and on the left side at the seat of fracture, a splinter of bone was found penetrating the brain. This was removed, whilst on the right side only a subdural and an epidural hæmatoma was reopened. The twitchings ceased after the operation, the paralysis continued until death, ten hours afterwards with increasing rapidity of pulse, until it became uncountable. Section showed a longitudinal fissure over the whole convexity of the skull down to the base, with extensive destruction of brain substance.

At the Medical Society Herr Mendel showed preparations from a case of

ACROMEGALY.

In November, 1895, the speaker showed the case and gave a history of it. In addition to the visible acromegaly there were hemianopsia bilateralis, struma, amenorrhœa, &c. There were violent headaches and vomiting, and in the free intervals between polyphagia and polydipsia. The patient died in October, 1899. Section confirmed the diagnosis previously given of the disease of the hypophysis. There was a tumour proceeding from the hypophysis which had destroyed it, and which had grown forwards and backwards on the dorsal aspect, and had reached the size of a walnut. Microscopically, it proved to be a myxosarcoma. Besides this there was a goitre the size of two fists with colloid contents, a persisting thymus (five ctm. in length), an enlarged spleen (twenty ctm. in length), small cysts in the ovaries, and mammae of enormous size. As to whether the other changes had any connection with the disease of the hypophysis that led to the acromegaly, there was nothing to show. Possibly the case showed that acromegaly was a general disease that implicated several organs that were functionally related to one another. Organo therapeutics put into use (fresh hypophysis substance from the slaughter-house) in this, as in other cases, left them in the lurch.

GASTRO-INTESTINAL DISINFECTION, BACTERIOLOGICALLY CONSIDERED.

At the same meeting Hr. Schütz, Wiesbaden, read a paper on this subject. The estimation of the value of the gastric juice in the digestion and absorption of material from the small intestine had receded, but the antiseptic power of a two per cent. solution of hydrochloric acid was uncontested. It was not improbable that this power was chiefly exercised in the stomach. It had been shown that there was no relation between decomposition in the intestine and gastric juice. The writer had endeavoured to study the flora of the intestine, and to compare them with those growing when hydrochloric acid was withheld. He had to find a species of bacterium which passed into the duodenum of the dog direct (without contact with gastric juice) and it did not appear in the fæces, therefore died in the intestine; further that the bacillus passed through the stomach under normal conditions, and that therefore H.Cl. was not an unsurmountable obstacle. Only one bacterium answered to these conditions, and that was the cholera vibrio Metchnikoff. The experiments were made on the dog as being equally omnivorous with the

human subject. After feeding with the vibrio and killing the animal, the faeces were then examined by cultivation. After describing the mode of preparation of the vibrios the speaker went on to say that the infective material was given in large quantities—in three young dogs five to fifteen milliards in four to eight weeks. After preliminary experiments which showed that under normal conditions the vibrio did not pass away in the stools, he proceeded with his experiments, and passed the infective material direct into the duodenum. Even without any influence from HCl no vibrios passed through the intestinal canal whatever quantity might be given. But if purgatives were given simultaneously (calomel, castor oil), then the stools contained the vibrios, for twelve hours after they had been given. As regarded post-mortem appearances, the small intestine was highly inflamed, as after cholera infection. The vibrios, even in large quantities disappeared before reaching the large intestine. The experiments showed that the vibrio passed through the stomach capable of development, even when given along with food that furthered the secretion of gastric juice. There was, therefore, a highly energetic power of disinfection in the upper parts of the bowel that indicated an antiseptic property in the bile. The speaker finally sought to explain how disinfection in the intestine acted on the bacteria of decomposition, and pointed out that calomel did not remove the germs, but that they continued to appear for twelve hours after administration, while in the other animals they had disappeared from the intestine within two or three hours after their last administration.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, January 6th, 1900.

TUBERCLE IN BUTTER AND MILK.

WISSENFELD, of Bonn, has confirmed many of the suspicious and bacterial examinations made in the laboratories of this city. Twenty examinations of milk at dairies and twelve at the farms in the Rhineland have resulted in the discovery of the genuine tuberculous bacillus. His experiments were carried out in the usual manner on guinea-pigs with control animals.

The deposits from butter and milk after passing through the centrifugal machine were injected into animals weighing 300 to 500 grammes in doses ranging from 0.5 c.c. to 5.0 c.c. Of the thirty-two tests twenty-two gave no reaction of tuberculosis in the animal organism. The remaining ten had a variety of phenomena. One test of milk from the Rhine province was undoubtedly tuberculous; while two others of butter from the farms, and having a large sale in the town as fresh, were also tuberculous. The remaining cases were well defined pseudo-tuberculosis.

Wissenfeld has gone further, and demonstrates that our so-called artificial nutrients from these products are also infected with the diseased germs and dangerous for consumption, particularly by invalids. He has tested "Nutrose," "Eucasin," "Kalkcasein," "Plasmon,"—"Siebold's Milcheiweiss"—and found large quantities of the bacilli which were evidently active from the confirmatory experiments carried out on animals.

STRUMECTOMY.

At the "Gesellschaft der Aerzte" Schrötter exhibited two cases which he had operated on and which had been before the meeting when one was diagnosed as a misplaced thyroid the other as a foreign body in the bronchi.

The displaced thyroid had descended so far as to press on the trachea and produce stercus with painful breathing. Strumectomy was performed under local anaesthesia. Ten cubic centimetres of a 1 per cent. solution of cocaine was applied to the tumour and it was removed without trouble. Immediately after the operation the patient was able to breathe freely without any cough.

The lead pencil which had lain wedged four months was removed from the bronchi by means of a long tube and forceps combined.

Weinlechner remarked that the removal of the thyroid gland was best effected by means of local anaesthesia as it abolished the coughing usually troublesome during the operation. He always applied it himself in the manner recommended by Mikulicz, which is by a compress fastened with an elastic band round the neck.

The Operating Theatres.

WEST LONDON HOSPITAL.

PATELLAR SINUS LEADING TO PRÆ-PATELLAR ABSCESS.

—MR. SWINFORD EDWARDS operated on a little boy, *æt.* 12, who had been admitted for abscess situated over the ligamentum patellæ. The articulation had within the past day or two exhibited some symptoms of inflammation so that it was feared the abscess might have burst into the joint. On this point Mr. Edwards remarked that as the boy's temperature was not very high being only 99, and as there was not much heat or redness about the joint, nor much distension, he was inclined to think that the pus had not found its way into the joint, but that the articulation was partly distended with some effusion owing to the juxtaposition of the abscess cavity. Such proved to be the case after the abscess had been exposed and thoroughly scraped of the granulation tissue lining it. From the upper part of the abscess cavity just below the patella a sinus was discovered through which a probe passed on to bare bone; thinking that this was on the articular surface of the patella Mr. Edwards opened the knee-joint on the outer side when about a tablespoonful of synovial fluid escaped, this was more watery in consistence than normal synovial fluid should be. On examining the articular surface it was found there was no erosion anywhere. With the patella now grasped between the finger and thumb, the former being in the joint and the latter outside it, it was found that the probe entered an abscess cavity in the interior of the patella which cavity had two outlets, one the sinus above referred to which entered the bone on its lower and inner border, the other on its lower and outer border; they both communicated with the exposed abscess cavity. The bony cavity was now thoroughly scraped out with a Volkmann's spoon, and a drainage tube inserted which was brought out through a separate incision on the outer side of the joint, the joint itself being drained through the original incision. Mr. Edwards remarked on the rarity of abscess in the

patella itself. Had he not believed the articular surface of the patella to be involved he would not have opened the joint; having done so, two courses he said were open to him, the one to sew up again the capsule immediately after opening it and after having washed it out with a weak solution of sublimate to thus shut it off again from the abscess cavity, the second which was to pursue the course he had adopted, namely, of draining the joint.

It is interesting to note that no ill-effects have followed this exposure of the joint, and the drainage tube was removed from the articulation at the end of forty-eight hours; the discharge escaping from the abscess cavity is diminishing daily in quantity, and is now, a week after operation, very small.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, JANUARY 10, 1900.

LOCAL AUTHORITIES AND ADULTERATION.

DESPITE the fact that of late years vast changes for the better have come over the spirit of vestrydom, there nevertheless remains, on the other hand, ample room for improvement. The importance of the branch of local government concerned is shown by the vast sums of money they are called upon to disburse with regard to roads, sewers, lighting, scavenging, sanitary and other administrative matters. It is vital to the welfare of the community, therefore, that they elect honourable and enlightened men to manage their local government, and it is only when the public interest is sufficiently aroused to make parochial elections thoroughly earnest and representative that irreproachable candidates are likely to be returned. At present there is no need to go outside the metropolis for examples of all kinds of sheer, crass maladministration and questionable expenditure. Money is spent freely in certain directions, while it is grudged upon things that are absolutely necessary from a public health point of view. The policy of the Local Government Board has always

been to interfere as little as possible with local administration. A time comes, however, in the history of many vestries and other local governing bodies when the central controlling board is compelled to interfere, and to insist upon the fulfilment of statutory duties. During the past year, Mr. Chaplin has had in this way to assert his supreme authority, both in London and in the provinces. It is not an altogether unreasonable surmise, judging from past experiences, that his interference may be called upon still further in the case of certain Vestries that have delayed and avoided necessary sanitary reforms in an arbitrary and unfavourable manner. In one instance, at least, an artful arrangement has come to light, whereby the reports of the Medical Officer of Health were strangled in their birth by a sub-health Committee, so that by the action of a small clique not only the Health Committee but also the Vestry were kept in ignorance of the representations of their Medical Officer as to nuisances and other matters vital to the health of the district. Unfortunately, instances in which a zealous and efficient Medical Officer of Health finds himself at variance with his vestry are not uncommon, and it is to be hoped that some scheme may be devised to prevent the gagging of such an official by methods of the kind above mentioned. Among the multifarious duties committed to the care of the vestries is that of the administration of the Food and Drugs Act, a function of direct interest to every ratepayer. As a rule, however, the matter is dealt with in such a slipshod way that the evil deeds of the adulterator are allowed practically to go unchecked. The year's work of an average vestry in this direction comprises a few prosecutions of milk-sellers, and the examination of a certain small number of samples of foods and drugs taken by the Vestry officials. The utter inadequacy of this test either to ascertain or to prevent adulteration must be apparent when it is remembered in what a host of ways this sort of fraud is perpetrated. If an inspector were to walk into a single grocer's shop and begin to take samples of stuffs known to be commonly adulterated he would come away with enough to employ the time of the official analyst and his staff for a month. Under the present lax system, however, out of the many millions of shops in the United Kingdom liable to the control of the Food and Drugs Act the majority escape even a superficial test. Not many years ago a little attention to the publicans revealed a widespread and scandalous adulteration of beer. Why has that investigation not been repeated? We venture to assert that a preconcerted seizure of samples of some common article of food, say pepper, throughout any given district would result in some startling revelations from the analytical laboratories. The reason of this apathy on the part of vestrymen as to the purity of foodstuffs is not far to seek. As a rule many of them belong to the tradesmen class, and they are not unnaturally averse

to interference with trade matters. Then, again, the Medical Officer of Health and his inspectors have already quite enough on their hands in other directions. As to that anomaly, the half-time Medical Officer of Health, no one could for a moment seriously expect him to look after such details as the purity of food and drugs. Yet various wealthy and crowded London parishes, such as St. Saviour's, Southwark, Bermondsey, and Holborn, do not think it necessary to employ more than a portion of the energies of one man as their Medical Officer of Health. It is a question whether, under existing circumstances, the administration of the Act should not be handed over to a central authority, such as the London County Council. Then, again, the Public Analyst service needs thorough revision. Pluralism, save under the most exceptional circumstances, should be sternly discountenanced by the Local Government Board, and payment should be by fixed salary. As things go there is no possibility of a public analyst discharging the duties of that post to several large and separate districts, that is to say, if the Acts are to be efficiently administered therein. It is to be hoped that before the close of the year upon which we have recently entered some efficient steps will have been taken by the Local Government Board, beginning with the headquarters at Somerset House, to secure the purity of the food of the people by the agency of existing laws.

THE DUBLIN HOLOCAUST.

INASMUCH as the mortality rate of Dublin City, as reported by the Medical Officer of Health, has reached the awful proportion of 46·0 per 1,000 of the population, while the rate for English and Scotch cities under similar circumstances of season and climate reaches only 18 or 19, no one can be considered too critical who speaks out respecting the ineptitude of the Dublin City Corporation, and of the citizens themselves. We fully anticipate the reasons which may be given by the Corporation for this terrible condition of Dublin sanitation, and, for the present, we admit their force. We allow that there are prevalent temporary epidemics which have increased the mortality roll, and we also admit that the miserable weather which has obtained in Dublin has brought in an increased harvest of deaths from pulmonary diseases, but we want to know why these adverse conditions should do more harm in Dublin than in other similarly situated districts? The answer given to this question is that in Dublin the population is ten times more receptive of infective disease—ten times more likely to die under such disease—and ten times more likely to succumb to respiratory disease than the denizens of other cities, and we are constrained to confess the validity of this defence. The simple fact is that the lower classes in Dublin are the easiest possible prey for disease in any form. Many of them have been nurtured and brought up in squalor and privation without a decent bed to lie on, or protective (not to say decent) clothes to cover

their nakedness, or moderately fair air to breathe, and, in their budding years of discretion they are gradually, but inevitably, broken in to the constant use of the vilest whiskey and equally atrocious tobacco. Seldom, from their infancy, do such receive an abundant and nutritious meal, or, until they are past puberty, rejoice in the ostentatious comfort of a warm suit of clothes. Is it wonderful that such items of a population die like murrained sheep when attacked by any of the assaults of disease which other communities experience, or that the mortality rate runs upon such occasions to 46·0 per 1,000 of the population? This is a matter which calls for no further investigation save as to the details of the remedy which should be applied. The "tenement house" has been marked down by two Commissions of inquiry and by the common consent of every critic as the *fons et origo mali*. These habitations of the Dublin poor are, in a majority of cases, the dilapidated wrecks of the mansions of the nobility and gentry, and of their aristocratic dependents, who kept state and squandered their patrimonies in Dublin in the time of the Georges, and these mansions, for the past hundred years, since the Union, have been abandoned and crumbling to ruin. The remaining shells of the houses are bought for a nominal sum by speculators and let out to the poor at a profit before which the income of the mines of Golconda or the dividend on Guinness's brewery are as nothing. It is possible to buy a magnificent mansion in some of these long ago fashionable streets for £30 or £50—a mansion with ceiling and fittings which must have cost thousands, and it is sworn before one of the Commissions that such a house, purchased for £30 brought in a steady income of about £250 a year. This monstrous profit is got by cutting up the palatial reception rooms into separate tenements by erecting lath and plaster partitions and often by shoulder-high divisions, which enable the owner to take rent from half a dozen tenants for one room. Thus, as many as seventy persons are sometimes huddled together in one house. To these sub-divisions there is, of course, no fireplace, nor any ventilation except such as is derived from the use of one or two windows (which are seldom opened) for the whole room, the cubic space of each tenement is, usually, whatever the owner likes to make it, and the only *cloaca* for the whole establishment is in the back yard down four flights of stairs from the top rooms. These tenement houses are frequently in possession of retired policemen or other people who have no capital, and are driven to wring the uttermost penny out of their investment by setting themselves against expenditure on improvements of any sort, or else the owners are speculators on the large scale, who are themselves members either of the Corporation or of the Sanitary Authorities, a position which enables them to oppose effective resistance to every suggestion of reform. Sir Charles Cameron, since his appointment as Superintendent Medical Officer of Health, has done as much as the very limited

supply of money which the Corporation allows, and the opposition referred to permits. He might institute a strict house-to-house inspection and might serve notice on the owners that he would, forthwith, close the premises if the necessary improvements were not effected but, if the medical officer dared to do this against the influential tenement-farmers he would still be face to face with the problem as to what would become of the multitude of poor tenants thus dispossessed for whom no other accommodation at present exists in the city. They would not thank him for interfering as, in most instances, they are insensible to the delights of cleanliness or decent comfort, and are only able to pay rent to the amount of 1s. to 2s. per week from which no speculator could make a profit if he had to provide decent accommodation. The Q. E. D. of all this statement of fact is that the mortality of Dublin city can never be materially reduced, nor can its lower classes be ever made clean and self-respecting until the tenement traffic is extinguished by providing, at the public expense, tolerable habitations for the poor. To do this would, in the long run, cost the citizens very little. Several sites can be had for almost nothing, their areas having been cleared by the tumbling down of the houses thereon—the buildings might be quite cheap though in all respects sanitary and suitable if only the architects and engineers could be deterred from decorating them in the æsthetic style, and, on these terms, the accruing rents would at least pay interest, sinking fund, and repairs, leaving the property clear to the Corporation at the lapse of the sinking fund. We have presented the subject in this form, not at all by way of apology for the crass incapacity of the Dublin Corporation, but to excite the citizens, who are almost as much to blame, to take the Corporation by the throat and insist on the immediate initiation of remedial measures. We are fully impressed with the belief that squalor, savage ignorance, poverty, and depravity cannot be cured by any method of administration, however enthusiastic, within a measurable period, but it is now, within our own knowledge, forty years, and we don't know how many more, since the bestiality of the life conditions of the very poor in Dublin has been as obvious, and, at this moment, the Corporators appear to be as indifferent to the deaths of the poor or the miseries of, and degradation of, their lives as ever they were. They can traffic with contractors for municipal work, or pass bombastic political resolutions; they can afford to pay out £91,000 for the building of villas for artisans (who are all voters), and £260,000 for an electric scheme, but they will not give one sixpence to the regeneration of the sick and dying poor population. Why should they? "Rattle their bones over the stones, they are only paupers whom nobody owns."

MORITURUS.

WELCOME has smiled too soon upon the twentieth century, and we have still another year before the

parting guest has flown. It rather seems as if we should have been glad if it were past if this would leave us freer to act as reason prompts in effecting certain desirable changes. Bad habits have been growing up which no one has cared to correct. In our article on the Past Century we referred to the men whose influence was paramount in matters of interest to the profession, when the nineteenth was young; and we drew attention to the spirit, that stimulated the best men to work as they did, and make the great advances that we can now look back upon with admiration. Of late, however, things have changed. Money has been the object which even science has had in view. Science like religion used not to bow to wealth or be patronised by it; but of late, in the relations between the public and the profession, those feelings which had influence in making the life of a good doctor not unenviable, have been passing away; and the services he rendered have been thought no different from those of an ordinary tradesman. The great body of the profession is beginning to suffer, and now questions are arising as to what course men will take collectively and individually in righting the abuses that their own indifference and, we fear, their self-interest have brought about. In the Church there has been trouble brewing for some time; and evil tendencies have been shown to pander to the weaknesses of Society. To have seen the Royal College of Physicians scheming to obtain control of the profession by extinguishing the Society of Apothecaries, and dominating the new University, through which alone the title of Doctor could be obtained in this great city, was not pleasant for those who took a very different view of how such matters should be conducted. It was nobody's business to oppose, and things looked as if they were going from bad to worse. Some men there were who had common sense, and were not so little Christian in spirit as to let injustice prevail. The College of Physicians has righted itself; and we hope that now the few months of the century that is dying out will be spent in some general call for an auditing of accounts, and in some movement to reform those abuses which under the guise of charity have been creeping in, to aid pretentious specialism to advertise itself, and take advantage of credulity and ignorance. To what extent the general Press has lent itself in advertising and in other ways we will reserve for consideration. It rests with the great body of the profession to correct these abuses, for they can do so if they please. If they do not do so they will suffer.

Notes on Current Topics.

The Field Hospitals for the Transvaal.

THE hospital equipment provided by the generosity of Lord Iveagh is expected to leave Southampton about the 20th inst. It will consist of 62 men, besides the surgeons and dressers, 20 waggons and

carts, drawn by 80 mules. There will also be 8 tortoise tents capable of accommodating the 100 wounded whom the hospital is designed to succour, besides 20 living tents for the staff. Female nurses will not accompany it. The whole will be under the administration of Sir William Thomson, of Dublin, as chief surgeon, Mr. George Stoker, of London, Mr. Friel, of Waterford, and a fourth civil surgeon who has not yet been named, and there will be 6 dressers, qualified men, who have been already selected. Major Mould, R.A.M.C., who has seen considerable service in the East, will accompany the expedition as military organiser, and Major Courtenay as financial commissioner acting for Lord Iveagh. Of these gentlemen it is scarcely necessary to say much. Sir William Thomson is the well-known Surgeon to the Richmond Hospital, Dublin, Senator of the Royal University of Ireland, ex-President of the Irish College of Surgeons, and Direct Representative for Ireland in the General Medical Council. Mr. George Stoker brings to the expedition invaluable experience in medico-military matters as one of the Stafford House Surgeons, and Surgeon in the Imperial Ottoman Army, and he is well-known to the profession as the exponent of the Oxygen method of treatment, and as an authority on throat diseases. Mr. Friel was a surgical travelling prizeman of the University of Dublin, and served with honour the House Surgeoncy of the Richmond Hospital. This hospital will be charged with duty on the line of communications, and will not be employed at the base hospitals.

The Post of Registrar-General.

THE Registrar-General has hitherto been regarded as a purely administrative officer in charge of an important department having for function to secure a permanent register of births, marriages, and deaths. The statistics, originally collected for purely social purposes, have since been made to serve other, perhaps much more important, purposes; indeed, it would be difficult to over-rate the value to the community of the deductions and conclusions drawn from these figures bearing on the incidence of disease and death. To the late Dr. Farr in his capacity of superintendent of statistics belongs the credit of having directed attention to the far-reaching importance of these statistics, especially in the direction of preventive medicine. Apart from the mere record of facts these statistics require for their co-ordination and analysis a man possessed of medical knowledge, who moreover is cognisant of the requirements of those to whom these statistics will appeal. Since Dr. Farr initiated his method of dealing with the records the importance of the labours of the superintendent of statistics has gone on increasing until they quite outshadow those on the purely administrative side. The Registrar-General collects the figures, but it is the privilege of the superintendent of statistics to classify them and clothe them with the scientific interest which they possess when presented to the public in the annual reports. The approaching retirement of Sir Brydges Henniker, the present Registrar-

General, under the limit of age, affords a favourable opportunity for urging the desirability of selecting a medical man to fill that responsible post, and if this point be conceded the present superintendent of statistics would obviously have a preferential claim. The ever-increasing extent to which these statistics, in their medical aspects, are made use of by the various health authorities justify the view that the lapsus which at present mars the accuracy of some of the returns would stand a better chance of being remedied under a medical registrar-general than under the guidance of a lay administrator, no matter how able. This feeling found expression in many quarters on the last occasion of the post falling vacant, but Dr. Farr's advanced age and uncertain health virtually excluded him from the succession. As no such objection presents itself now it may be hoped that this aspect of the question will be borne in mind in choosing a successor to the able administrator who is shortly to retire.

Funeral of Sir James Paget.

THE funeral service over the body of Sir James Paget took place at Westminster Abbey on Friday last with a pomp and ceremony worthy of the illustrious dead, whose memory a large number of friends and admirers had assembled to honour. The coffin was covered with wreaths and flowers sent by the Prince and Princess of Wales, the Baroness Burdett-Coutts, the staff of St. Bartholomew's Hospital, and others. Her Majesty was represented by Captain N. C. Phillips and Dr. Barlow, the former bearing a wreath of roses inscribed "A token of respect and esteem.—Victoria, R.I." The procession was met at the gate of the Abbey by the clergy and choir, and the opening sentences of the Burial Service were chanted to Croft's setting as it advanced into the choir. The lesson was read by Canon Duckworth, after which the choir sang Sir H. Oakeley's beautiful anthem, "Comes at times a stillness as of even." After the benediction, the coffin was carried out of the Abbey by the west aisle and conveyed to Finchley where the interment took place.

Professor Schenk in Disgrace.

THE worldwide notoriety which Professor Schenk attained on the publication of his ingenious theory of the determination of sex, based, alas! on too slender a foundation of research and observation, appears to have given umbrage to his colleagues in the University of Vienna. The work in question was formally censured by the Disciplinary Council of the College of Professors, and a petition was addressed to the Minister of Public Instruction asking that the author might be removed from his chair and deposed from the management of the Embryological Institute. The petition has been so far acceded to that the professor has been accorded unlimited leave of absence, with an intimation that he is at liberty to apply for a pension. In view of the fact that Professor Schenk has been at the head of the Institute for something like twenty-six years, the general

impression, at any rate, in the lay press, seems to be that he has been hardly dealt with, but the critics overlook the special obligations and responsibilities attaching to the honoured position of professor, and it is quite unfair to place Professor Schenk on a footing with Koch, who was only partially responsible for the premature publication of his researches on tuberculin, and whose valuable contributions to science in many directions place him on a pedestal apart. The worst punishment for the unfortunate professor is the consciousness that he will go down to posterity as the originator of what Lowell called an "exploded idea." This is the fate which awaits those who allow their thirst for fame to outrun their scientific discretion.

Severe Type of Influenza in Edinburgh.

OUR "Own Correspondent" informs us that Edinburgh is at present in the throes of a severe type of influenza, especially attacking the lungs and the temperature mechanism. We regret that one of the most recent victims was a very promising member of the profession, Dr. George Elder, F.R.C.P.E. Dr. Elder, who was only thirty years of age, had a most distinguished University career, and at the time of his death was a clinical tutor at the Royal Infirmary and an assistant physician to Leith Hospital. He was also joint author along with Dr. J. E. Fowler of a text-book on children's diseases. His early decease cuts short a career of great promise, and is a source of deep regret to his many friends.

Post-Graduate Tuition at the Cape.

THE war in South Africa has so dislocated affairs in the Colony that the *South African Medical Journal*, many of whose subscribers reside in the Transvaal, Orange Free State, and Natal, has announced with its December issue that it will cease to appear for six months. We have, however, in the copy before us read with much interest the proposed scheme by Dr. Darley-Hartley, of Cape Town, for establishing a Post-Graduate centre in the Colony. Dr. Hartley, in speaking in glowing terms of the West London Post-Graduate College, says that "it affords especially valuable guidance," for his scheme, inasmuch as it carries on its work under conditions fairly approximate to those that exist in Cape Town. It may be pointed out that Dr. Darley-Hartley was a year ago a member of the West London Post-Graduate College, and that he still maintains his interest in the hospital and its work by being a subscribing member of the West London Medico-Chirurgical Society. His grasp of the requirements of post-graduate teaching is well shown by the thoroughly worked-out scheme which he has elaborated for organisation in Cape Town; that is really the essence of the whole matter—namely organisation. Unless this be such as to touch the pulse of those requiring post-graduate aid, no success is likely to be attained. Nor is it an altogether easy matter to supply post-graduates with exactly what they want. The first *sine qua non* is undoubtedly a large general hospital, with its various fully equipped departments

Then there is the teaching staff, who require to possess, some at least, capacity for this purpose. According to Dr. Hartley, the provision of lecturers and material would probably be the most difficult part of the enterprise in Cape Town. However, these are details which no doubt will be overcome satisfactorily in the course of time, and meanwhile we can only express our hearty wishes for the success of the movement which Dr. Darley-Hartley has inaugurated.

The Bakers Again.

THE journeymen bakers are in a chronic state of revolt, and the community at this present moment is threatened with a strike on a large scale. In London alone it is estimated that some 14,000 men will thus withdraw from that necessary occupation. Their chief demand appears to be for a shorter week than 70 hours, a request that seems reasonable enough on general grounds, to say nothing of the facts that the trade is unhealthy and the wages poor. Some years ago a great outcry was raised against the cellar bakeries and the conditions under which bread was made in the smaller bakehouses. Government has since made it illegal to start any new bakehouse underground. Clearly, inasmuch as a vast number of such places are already in existence, the fresh legislation simply touches the fringe of the evil. The old underground bakehouses, with all their noisome and insanitary surroundings, remain for the most part untouched. The vestries refuse to enforce a decent sanitary standard, because they are loth to interfere with tradesmen in their districts. The journeymen bakers are apparently not well enough organised to insist upon proper housing and decent wages. The public seem apathetic as to whence their bread comes and under what conditions it is prepared. Some years ago, at the Bristol meeting of the British Medical Association, a paper was read showing that baking did not necessarily destroy harmful germs contained in the dough. Those experiments have a most important bearing on a possible means of distribution of such diseases as cholera, summer diarrhoea, plague, and enteric fever, but so far as we know they still await confirmation by some public health authority. The only hope of efficient control of bakehouses seems to lie in the direction of a central authority. In London the powers should be vested in the County Council, to be carried out by a special staff of skilled inspectors. In many ways machine-made bread is more wholesome than that made by hand, at any rate, its methods of preparation are infinitely more cleanly.

The Lesson of Vaccination at Hull.

THE town of Hull has had to pay dearly for its lesson in vaccination. The chairman of the Sanitary Committee of the Corporation announced last week at a meeting that the cost of vaccinating and re-vaccinating the townspeople had amounted in fees to the medical men to £7,500 during the past twelve months. The rates, therefore, will be bur-

dened to this extent, and nothing could be more calculated than the raising of the rates to bring home to the community the folly of refusing to abide by the teaching of vaccination. The returns show that 80,000 persons were vaccinated or re-vaccinated, of whom about 20,000 would be private patients of the medical practitioners of the town. The townspeople, however, may take some consolation from the fact that they are not likely for some time to suffer from another epidemic of small-pox. They have now wisely protected themselves, and if in the future they bear in mind the lesson in vaccination which they have just been taught, a visitation such as that which brought death, disease, and loss of trade in its train will not be their lot again.

French Doctors Painted by French Authors.

SINCE the days of Molière, French authors have shown scant sympathy with the practitioners of medicine, but as a general rule their gibes have been directed against the mysticism and alleged ignorance of the followers of *Æsculapius*, in fact, the attacks were satirical rather than critical. During the last few years the attitude of authors has undergone a change for the worse in that they appear to take a wicked pleasure in holding the doctor up to obloquy and contempt by more or less precise allegations of venality and actual professional misconduct. The ignoble author of "*Le Mal Necessaire*" paints the clever but unscrupulous surgeon who operates for a fee without the slightest regard to the necessities of the case and the interests of his patient, and winds up by representing him as performing total hysterectomy on a young lady who was pregnant as the result of the advantage he had taken of her temporary unconsciousness some months previously. Léon Daudet, the unworthy offspring of a great sire, in the *Morticoles* wove a dreary but highly-coloured picture of a hypothetical world in which doctors were all powerful, and he paints them as capable of every crime and of every abuse. Still more recently Zola in his "*Fécondité*," with his peculiar facility for unearthing the hideous in life, introduces us to the abortionist doctor and the unscrupulous surgeon, nicknamed "the universal steriliser," in short, he leaves a very disagreeable impression on one's mind of medical practice in Paris, if not in France as a whole. If these authors and others are to be believed, morality, and even mere honesty, are conspicuous by their absence among French practitioners, even in the highest ranks of the profession. Dichotomy, the practice of sharing fees extorted from patients, is reputed to be quasi-universal, and any idea of a responsibility towards the patient is everywhere scouted. We decline to accept the pictures as true to nature, for the profession in France could not continue to exist were its morality at as low an ebb as we are invited to believe. At the same time there undoubtedly exists scope for reform in that there is no body corresponding to our General Medical Council possessing the power of weeding out the unworthy. The French doctor may advertise in the most unblushing manner without let or hindrance,

and provided he keeps clear of the criminal law he is amenable to no disciplinary jurisdiction. Even after conviction apparently he is free, as soon as he has purged his offence, to recommence practice so that the ranks of the profession inevitably comprise many black sheep. The pity is that French writers select these black sheep for their heroes or villains, as the case may be, to the detriment of the reputation of the profession as a whole.

The Lutterworth Guardians and Vaccination.

THE Lutterworth Guardians have been fighting the Local Government Board for a year upon the question of the control of their vaccination officer. The Board refused to ratify the last appointment of such officer by the Guardians because it embodied illegal limitations in his duties, and this took place a year ago. The Guardians a week or two ago were, therefore, requested to make an appointment forthwith. This order has now been carried out, the officer appointed having simply to fulfil the requirements of the Act without any restrictions. But the Guardians did not take the "snubbing" of the Local Government Board kindly. One sagacious member protested strongly against being, as he described it, "over-ridden by Mr. Chaplin." But it was pointed out to him that unless they obeyed the instructions of the Board their fate would be similar to that of their colleagues at Leicester. Thus the example made of the Leicester "martyrs" is proving eminently useful to the country.

Sensational Discoveries.

NOR so many years ago the main source of wonderful occurrences and discoveries was the United States, but since the realisation of the telephone, the phonograph, and sundry other exceedingly curious but very authentic marvels, we have learned to take American discoveries more seriously. The mantle of Elijah now seems to have fallen on French shoulders, and every year brings its array of wonderful discoveries, by no means always duly authenticated, from over the channel. Poor Brown-Séquard gave the scoffers a chance when he promulgated his new elixir *v.tæ*, but though this has made the fortunes of pharmacists it has failed to conquer a place of honour in the domain of what we may call vital therapeutics. Then, or possibly earlier, Pasteur discovered a cure for hydrophobia which, to put it mildly, is still on its trial but, if not all that is claimed for it, this discovery has a sound basis of scientific research which may even yet secure its triumph. The most sensational discoveries, however, have been reserved for the last few months. We have been treated to an announcement of the discovery of a body which should be capable of furnishing oxygen in profusion without trouble and at trifling expense. It turns out that the body in question is a salt of vanadium, but though interesting from a physical point of view, its practical utility in medicine has yet to be shown. Proceeding, *crescendo*, the great Dr. Metschnikoff, whose epoch-marking researches in bacteriology erstwhile startled the

scientific world, puts forward a claim to have discovered a serum capable of delaying, if not preventing, the sclerotic changes which characterise senile decay, in other words, of staying the activity of the macrophages, the variety of phagocyte which determines these changes in our tissues and organs as soon as the vitality of the cells begins to fail, by reinforcing the latter. We gather that he does not promise terrestrial immortality, but merely death from genuine old age, and not from some intercurrent disorder of the sclerotic kind. To close the list there is the discovery of a serum—the ubiquitous serum—obtained from alcoholised animals, the injection whereof is guaranteed to excite in the subject of the experiment an invincible repugnance for all alcoholic beverages. A special committee has been appointed by the French Academy of Medicine to investigate the subject, whose report we shall await with sceptical interest.

Unwholesome Condensed Milk Again.

THE urgent necessity for strict control of the supply of condensed milk has once again been shown by the successful prosecution of a city merchant who was found in possession of 156 cases of putrid condensed milk. The unsatisfactory feature of these prosecutions is that the guilty parties are let off with a pecuniary fine instead of being sent to prison. A very trifling offence against property is promptly punished by a term of imprisonment, whereas this very grave and wicked fraud is thought to be adequately punished by a mere fine, a fine, moreover, nothing like large enough to act as a deterrent in view of the immense profits attending such sales. By and bye, perhaps, our legislators will learn to treat the sale of injurious products for food as a crime akin to arson in that the delinquents deliberately set free destructive forces capable of working immeasurable harm.

The Drugging of Beer.

OF all popular myths there is none more firmly rooted in the mind of the public than that of the drugging of drinks, whereby the would-be criminal of various grades is enabled to rob his victim of the power of resistance. The latest sensation of the kind, unearthed by the *Westminster Gazette*, relates how thieves invite likely persons into a public house, and drop into their beer some chloral crystals, a drug which sends them "to sleep almost at once." The journal quotes some remarks made by Sir Henry Littlejohn, as witness in a recent case to the following effect; "He was sorry to say that chloral was too easily obtained by the vulgar. It was a perfect disgrace to society that so much facility existed for the possession of this most potent drug. Women and men, boys and girls, could get possession of it without let or hindrance." So far as it goes that expresses advanced medical views upon the subject. The practically unrestricted sale of chloral and of other potent drugs is nothing short of a scandal that demands the earnest and constant attention both of the General Medical Council and of the legislature. It

should be noted, however, that Sir Henry does not commit himself in the above quoted passage to any opinion as to whether criminals are in the habit of administering chloral in beer. There are, as a matter of fact, many reasons against such a "hocussing." In the first place, chloral has a most nauseous taste, which would not be disguised by the flavour of any malt liquor. Secondly, it would take a large dose—say, half a drachm to a drachm—to induce sleep within a period that may be estimated at about half-an-hour. That effect, moreover, would be inconstant. If a man were already intoxicated, no doubt the chloralised beer might escape detection, and hasten the advent of narcosis. Meanwhile, the drugging theory had better be left to its legitimate field in the novel and on the stage.

The Pathos of Medical Practice.

THERE is undoubtedly a pathetic side to the incident of a medical man attending a patient, when the former is much more in need of medical attendance than the person who has sought his aid. But the pathos is greatly increased when at the bedside of a patient the practitioner suddenly falls dead from some long standing malady. An incident of this kind occurred last week. Dr. Gimson, of Fitzroy Square, was summoned to a patient in Wigmore Street. After a short conversation with his patient, Dr. Gimson sat down in a chair, and in a few moments he was found to be insensible. At the inquiry which took place before the coroner, evidence was given of a post-mortem examination which had been made, and death was found to have been caused by the rupture of an aneurysm of the aorta. That is to say that probably for many months this practitioner had proceeded about the arduous duties of his practice, administering relief to suffering humanity, while suffering himself from a malady which required careful treatment and rest.

Hospital Subscriptions and the War.

THERE can be no doubt that the stream of private charity that flows with such ample tide in the British islands will be in no small amount diverted from its wonted channels. The cost of a great war is enormous both directly in life and treasure, and indirectly in the increased price of commodities. The surplus money of the nation, therefore, will be diminished so far as charitable disposal is concerned, and the actual sum available will be drained for the purpose of furnishing aid to our sick and wounded soldiers at the Cape and to their wives and families at home. The medical charities of the United Kingdom must perforce suffer from this unusual demand upon the generosity of the philanthropic public. Already instances of subscriptions withdrawn or curtailed on account of the war have been brought to the notice of hospital committees. For the present it is not easy to see in what direction one may look for a remedy to a somewhat alarming state of matters. If the worst comes to the worst we may perhaps still look hopefully to the inexhaustible benevolence that characterises our countrymen for

help to tide over the emergency. Or possibly the Government may extend national aid to the medical charities. There is another aspect of the subject that will commend itself to the Hospital Reform Association and kindred bodies, namely, that the medical charities should face the position and cut down their expenditure to the last penny in order to be ready for the years of the lean kine. A prudent reduction of the wholesale and indiscriminate relief granted in the out-patient departments would convert the position of many an institution from one of precarious struggle and beggary to that of comfortable competence and independence.

Sentiment and Philanthropy.

MUCH of England's manhood, and some of its best, is now in South Africa fighting for Queen and country, and much, we fear, is destined never to return. But, after all, the Empire is engaged upon a struggle which is necessary to its existence. Just as in the wars of the last century the nation was called upon to make many sacrifices, so now it may be, after many years of comparative peace, that the expenditure of English blood will prove, before the war ceases, to be a sore trial to the nation. In the midst of grief, however, there is always some consolation to be derived from taking measures to adopt some suitable means of perpetuating the memory of the dead, and in this connection, we may ask, could any more desirable method of doing so be suggested than that of endowing a bed at a hospital. By this means the name of a relative, killed in the service of his country, could be memorialised for ever afterwards in close association with a good work, and at the same time serve as an object lesson to every patient by whom the bed was occupied. This suggestion we commend to all those who, with wealth at command, may lose near relatives in the war of rebellion in South Africa.

Election of a Councillor of the Royal College of Surgeons, Ireland.

THE Fellows, on Monday last, proceeded to select a Councillor of the College in the room of Mr. Wheeler deceased. As we have already stated two candidates offered themselves—Mr. Ball Regius, Professor of Surgery in the University of Dublin, and Mr. Arthur Chance, Surgeon to the Mater Misericordiae Hospital. 224 voting papers were sent in, and, after the scrutiny of them, it was declared that Mr. Chance was elected, having scored 126 votes as against 98 for his opponent.

It affords as much pleasure to accede to the request of Messrs. Burroughs, Wellcome and Co., that we should inform our readers that they are supplying as a gift, the entire medical equipment of the City of London Imperial Volunteers throughout the present war in South Africa.

PERSONAL.

DR. ANDREW TURNER, Senior Assistant Physician at the West London Hospital, has resigned his post.

SIR JOHN WILLIAMS was entertained last week by the members of the Cardiff Medical Society, when he delivered an address on the present position of gynaecology.

MAJOR J. F. DONEGAN, R.A.M.C., who was left in Dundee in charge of the wounded on the retirement of the British troops, is now a prisoner in Pretoria.

SIR GEORGE ROBINSON SCOTT, K.C.S.I., Indian Medical Service, has retired from the Service, and intends to seek a Radical constituency with a view to entering Parliament.

DR. CONAN DOYLE, the popular dramatist and novelist, has, we understand, decided on relinquishing literature for the present, and will proceed in a few weeks to the front in charge of an ambulance hospital.

THE Executive Committee of the Liberal Association have nominated Dr. W. J. Collins, who is a graduate of the University and a former Chairman of the County Council, as Liberal candidate for the London University, consequent upon the elevation of Sir John Lubbock to the Peerage.

PROF. W. WATSON CHEYNE, F.R.S., F.R.C.S., and Mr. G. Lenthal Cheate, F.R.C.S., Surgeon and Assistant-Surgeon respectively to King's College Hospital, London who have left for the Seat of War, were entertained at dinner by the residents and students of King's College Hospital on Thursday last at the Hôtel Métropole.

MR. WATSON CHEYNE and MR. CHEATE left Waterloo for Southampton *en route* for South Africa on Saturday last, and the students of King's College Hospital gave them a hearty send off.

COMING events sometimes cast their shadows before, but, however that may be, the *New York Medical News* is rather "previous" in referring to Mr. George Brown, the direct representative on the General Medical Council, as "Sir" George Brown. Mr. Brown shares this honour with "Sir" Chamberlain and the late "Sir" Gladstone in the Continental Press.

H.R.H. THE PRINCE OF WALES presented on Saturday the service medals of the Order of St. John of Jerusalem to Mr. Samuel Osborn, F.R.C.S., Chief Surgeon of the Metropolitan Corps; Lieut. Chas. J. Trimble, L.R.C.P. Deputy Commissioner, and Mr. Chas. H. Tamplin, M.R.C.S., of Ramsgate, Hon. District Surgeon.

SIR WILLIAM GOWERS, Mr. Malcolm Morris, Dr. St. Clair Thomson, with several others, have left England on a visit to Sicily, where they are to inspect a palatial sanatorium recently erected for the treatment of phthisical patients. On the way they visited various scientific institutions at Rome and arranged for the establishment of systematic intercommunication between the Roman School of Hygiene and the London School of Tropical Medicine. The trip is expected to last about three weeks.

MEDICAL SOCIETY OF LONDON.

At the meeting of the Society on Monday evening last, Mr. Mansell Moullin reported two cases in which he had removed the vesiculæ seminales in young adults for tuberculous disease extending upwards from the epididymis. After removal of the testis and division of the cord as high up as possible with the patient in the lithotomy position, the under surface of the prostate and base of the bladder were exposed through a semilunar perineal incision running transversely. There was little bleeding in either case, but in one a small urinary fistula persisted for some months. He strongly advocated complete removal of the vesiculæ seminales and vas deferens in every case of tuberculous disease of the epididymis, in which the vesiculæ could be felt distinctly through the rectum.

Mr. Swinford Edwards observed that the operation was by no means a simple one, and suggested a modification of Kraske's operation.

Mr. Wallis also thought sufficient stress had not been laid on the technical difficulties.

Dr. Gow gave the result of a number of cases in which he had performed hysterectomy for fibroid with a mortality of about 2 per cent.

Dr. Blacker urged that with such a low rate of mortality many women might be now advantageously operated upon. He commented upon the gravity of adhesions, and related a case of his own in which they rendered removal of the tumour impossible. He agreed as to the desirability of preliminary ligation of the cervical tissue.

Mr. Wallis remarked on the extreme simplicity of the author's methods, which he suggested was the secret of his success, and Dr. Gow, in reply, pointed out that laceration of the uterus early in the operation caused bleeding which obliged them to rush the remainder of the operation.

Correspondence

We do not hold ourselves responsible for the opinions of our correspondents.

THE VALUE OF EMMENAGOGUES.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—It would, I think, be impossible for anyone who has seen the cases recently under treatment at the Westminster Hospital to doubt the efficacy of certain emmenagogues in the treatment of functional amenorrhœa associated with anemia. A chlorotic girl, æt. 19, comes before us with a history of having seen nothing for seven months. She is not pregnant, and there is no organic disease to account for her condition. She is put to bed, is fed on the best and most nourishing food, is given iron in full doses three times a day and the bowels are kept freely open. At the expiration of three weeks there is not a vestige of improvement. She is then put on manganese, her colour at once improves, and a fortnight later she menstruates freely. We find from an examination of the blood that it is a case of oligocythæmia with considerable oligochromæmia. Before the administration of the emmenagogue the blood taken from the finger (10.45 a.m.) is very pale in colour and contains only 3,830,000 red blood corpuscles per cmm. The colourless blood corpuscles number 3,000 per cmm. and consist chiefly of lymphocytes and finely granular oxyphil cells (polynuclear leucocytes).

This is the report after the cessation of the period:—

Blood taken from finger at 10.30 a.m. The drop appeared of good colour and flowed easily. Hæmaglobin 98 per cent.

Red blood corpuscles of good shape and uniform size, but a few megalocytes present. No nucleated erythrocytes found. Number = 4,725,000 per cmm, i.e. slightly above normal in the female.

Leucocytes between 11,000 and 12,000 per cmm. divided among varieties as follows:—

	per cent.
Finely granular oxyphil cells (multinuclear leucocytes)	71
Coarsely granular oxyphil cells ("eosinophil cells")	2
Large uninuclear cells "hyaline cells"	20
Lymphocytes	7

The number of hyaline cells is above, and that of lymphocytes below, the normal, but as there had been some considerable lapse of time since the last meal this is not extraordinary. In a word, the blood was in all respects like that taken from a healthy female.

Observations on other cases afford equally conclusive results.

These blood analyses are made not by me but by Dr. Lazarus Barlow, who has never seen the case and has no suspicion that anything new in the way of treatment is being attempted. What more in the way of proof is required I do not know, for the observations are made with all the care and accuracy of laboratory experiments. They show conclusively the value of emmenagogues in these cases, and illustrate incidentally the importance of having attached to a hospital a skilled pathologist, whose work cannot be influenced by any pre-conceived opinion as to the value of the remedial agents employed. I sometimes hear people say that they fail to obtain good results from the administration of emmenagogues, but it generally turns out on inquiry, that the drugs they are using do not belong to this class at all, but are only the reputed emmenagogues of the text-books.

The paper on permanganate of potassium in amenorrhœa by Dr. Ringer and myself was published in the early part of 1883, and our results have since been amply confirmed. My recent observations on the action of the soluble citrate are simply a development of the idea. On April 25th, 1894, you sir, were good enough to give hospitality to my paper on Senecio and Senecin. Dr. W. E. Fothergill's paper on the "Use of Senecio in Disorders of Menstruation," which obtained the Milner-Fothergill Gold Medal in Therapeutics in the University of Edinburgh, throws additional light on the subject.

I am, Sir, yours truly,

WILLIAM MURRELL.

Welbeck Street, W.

THE TEMPERANCE AND FOOD QUESTIONS AS THEY AFFECT HEALTH.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I am much interested in the temperance and food question, and I venture to think they should be considered together. I have read Dr. Edmund's paper in your issue of December 6th. I know well how earnestly he has for many years advocated the temperance cause, and I wish he would also look into the question of food reform. They are both equally needed for the raising of society generally, for all want raising. The leaven of truth with respect to the food question is not yet working as it ought to work and as it doubtless will work before long. The process is necessarily a slow one. All advance is slow, whether with regard to individual discipline and freeing oneself from bad habits, which are as chains about so many of us, or with regard to national progress which is equally stereotyped. Every blow, however, sends the nail of truth deeper into the inert mass of blind prejudice which appears to be the rule of life with the majority.

I wish I could get Dr. Edmunds and many others to take up the food question. I can assure them there is a mine of interest in it for the true reformer, as well as a mine of health, when properly understood and practised. I can also say from personal experience that to discipline oneself conduces far more to peace and happiness, as well as to health, than to gratify one's appetites and passions, and it induces a condition of body and mind that robs life of half its worries by the peace and quiet that result to the whole system.

In my own person I have been testing these facts, and my experience of now over three years justifies me in saying that I believe there is an immense amount to be learnt from observations as to the effect of various dietaries with regard to health and disease. Such obser-

vations, however, are not and cannot be made in a hurry, or conclusions arrived at hastily; but they are, in my opinion, of such importance to all classes of the community, capable of thinking and reasoning, as to call for and justify any amount of trouble that will tend to the development and preservation of a sound mind in a healthy body to extreme old age. I may say that I am now in my seventy-seventh year, and that I hope at a future period to submit to the profession both myself and some interesting experiences which I have already accumulated, and that I am further working out and testing in my own person. In the meantime, perhaps, Dr. Edmunds will give us his views of vegetarianism from the standpoint of a philosophical epicure, minus personal experience.

I am, Sir, yours truly,
Kilburn Priory, C. J. HARRIS, M.R.C.S.
January 6th, 1900.

THE WAR—AN APPEAL TO THE YOUNGER MEMBERS OF THE PROFESSION.

THE following appeal has been sent us for publication:—

In the crisis through which our Empire is passing the importance of the Militia, Yeomanry, and Volunteer forces as a support to the army is fully evinced. And as it is impossible to forecast the further demands which may have to be made upon them in the near or distant future, it behoves us to strengthen them to the utmost of our power.

Many members and students of our profession are already enrolled in them and are answering the call now made upon them with patriotic promptitude. We venture to take the opportunity suggested by the beginning of the New Year of appealing to such of the younger members and of the students of the medical and dental professions as are still unattached, yet capable of bearing arms or in other ways of helping in Imperial defence, at once to consider the advisability of joining some branch of the service.

FREDERICK T. ROBERTS, M.D., F.R.C.P.Lond.,
Physician to University College Hospital;

EDMUND OWEN, M.B.Lond., F.R.C.S.Eng.,
Surgeon to St. Mary's Hospital;

WILLIAM COLLINGRIDGE, M.A., M.D.Cantab.,
Surgeon-Lieutenant-Colonel Militia Medical Staff; late commanding Militia Medical Staff;

WILLIAM DUNCAN, M.D.BruX., F.R.C.S.Eng.,
Captain Middlesex Yeomanry Cavalry;

J. EDWARD SQUIRE, M.D., M.R.C.P.Lond., M.R.C.S.Eng.,
Surgeon-Lieutenant-Colonel Commanding Volunteer Medical Staff Corps (London Companies).
London, Jan. 1st, 1900.

A DISCLAIMER.

To the Editor of THE MEDICAL PRESS AND CIRCULAR

SIR,—I have read your leaderette in THE MEDICAL PRESS AND CIRCULAR, January 3rd, 1900, prematurely condemning me for a supposed breach of professional etiquette, and stating that I had contributed a signed article to a trade journal called "The Dioptric and Ophthalmometric Review." I beg to state that I have neither contributed a signed nor unsigned article to the said journal on any subject, nor did I even know of the existence of such a journal until I saw it mentioned in yours this morning. I wrote a paper on "Tobacco Amblyopia" for *The Hospital*, a professional paper of recognised standing, which I find on inquiry was duly published in its issue of December 2nd, 1899. That is all I know of the matter.

Meanwhile, as you have given such publicity to the mis-statement, I shall expect you to give equal publicity to my denial of contributing a signed article to the aforesaid trade journal, and as you have also drawn the attention of the Ophthalmological Society, of which I am a member, to the matter, to also see that each member of that Society receives a marked copy of your issue containing my absolute denial.

I am, Sir, yours truly,
CLEMENTS HALLES, M.D., F.R.C.S.Edin.,
Bristol Eye Hospital.
Hawkesdale, Clifton, Jan. 4th, 1900.

[We regret that we should have been misled into supposing that our correspondent contributed the article direct to the trade journal mentioned. As, however, the article was "lifted" without acknowledgment he can compel the proprietors of the "Dioptric and Ophthalmometric Review" to pay him for this infringement of copyright.—ED.]

Laboratory Notes.

RECENT PHARMACEUTICAL PRODUCTS.

AMONG the recent additions to "new remedies" and "pharmaceutical elegancies" emanating from Messrs. Parke, Davis and Co., it may interest our readers to be made aware of the "Sterilised Concentrated Saline Solution," which, on dilution with a suitable quantity of pure water, forms a normal saline solution, ready for emergencies. Every surgeon and obstetrician ought to have a supply of these phials in his bag, ready for use as and when occasion may require.

The popular combination of Colchicine with Methyl salicylate is put up in neat little capsules for the treatment of gout and certain forms of rheumatism. These are small and well made, and each contains an average dose for repeated administration.

Of the fluid extract of Pichi we know less, but it has a reputation in the States of being a "tonic diuretic," contraindicated in organic disease of the kidneys, but very useful in stimulating diuresis, and assisting in the elimination of uric acid.

The object of the globules of Saw Pa'metto and Santal Oils is too obvious to require mention. They represent a very useful combination, and we have found them very serviceable in vesical and urethral conditions calling for this kind of medication. This combination offers several advantages over the remedies most in vogue.

The uniformity of weight, and the finish of Messrs. Parke Davis and Co.'s products call for special commendation, and they must commend themselves to the favourable notice of fashionable practitioners.

Literature.

DE MERIC'S FRENCH-ENGLISH MEDICAL DICTIONARY. (a)

THIS volume completes the English-French, French-English Dictionary of Medical Terms, the first volume whereof was favourably noticed by us early last year. In compiling such a work it is, of course, very difficult to decide where to draw the line in the selection of words. It is obviously very difficult to limit the selection to words which are essentially and exclusively afferent to medicine and the allied sciences, and the author appears to have made up his mind not to err on the side of exclusion, though even then one is surprised to see such words as *mauvais*, *mid*, *mineral*, *cog*, and the like. No one, however, will grumble at a dictionary on the ground that it gives more information than was bargained for, while on the other hand, the patience, skill, and erudition of the author are testified to by the extraordinary range of his vocabulary.

Although many of the terms are as unfamiliar to us in English as they assuredly are in the French original, it is impossible to deny that the author has exhausted his subject, and his work will remain as a monument from the stones whereof less ambitious compilers may, at their leisure, build up less comprehensive works.

In spite of close scrutiny we have been unable to discover any inaccuracies or indeed, anything calling for adverse criticism. The book is smaller than its companion for reasons given in the preface, it is admirably printed, and the choice of types has been most judicious.

(a) "Dictionnaire des Termes de Médecine, Français-Anglais." Par H. de Meric, M.R.C.S.Eng., Chirurgien de l'Hôpital Français à Londres, &c. Part II., completing the work. London: Baillière, Tindall, and Cox. 1899. Price 4s. net.

We congratulate the author on the termination of what must have been a very trying and arduous task.

NUNN ON CANCER. (a)

In this little book the author has re-arranged observations and facts published in his "Essay on Cancer of the Breast." After a few words on the structure of cancer (which is well illustrated by plates at the end of the work) Mr. Nunn deals with the life history of the disease, dividing it into the initial, the transient, or dynamical, and the final, or obsolete. He then gives interesting short accounts of regional frequency, the age of greatest liability or vulnerability, geographical distribution, and heredity and longevity. The work is completed by the histories of fifty-three interesting cases, and by eleven very excellent plates of microscopical sections.

ENLARGEMENT OF THE PROSTATE. (b)

A SECOND edition of this practical work is very welcome. In it the author has omitted those operations on the prostate described in the first edition which were chiefly of historic interest. Many of the other chapters, however, have been lengthened, especially the one on the effects of enlargement of the prostate, the one on diagnosis, the two on local treatment of enlargement of the prostate, whilst a very complete résumé of the effect upon enlargement of the prostate, orchidectomy and of operations upon the structures contained in the spermatic cord takes the place of the short chapter on castration. The book at present is certainly a very complete and up-to-date epitome of the surgery of the prostate.

The Medical Sickness and Accident Society.

THE usual monthly meeting of the Executive Committee of the Medical Sickness, Annuities, and Life Assurance Society was held at 429, Strand, London, W.C., on 29th ult. In the absence of the Chairman, Dr. de Havilland Hall, the chair was occupied by Dr. Major Greenwood, and there were also present Dr. J. B. Ball, Mr. J. Brindley James, Dr. W. Knowsley Sibley, Mr. F. S. Edwards, and Mr. Edward Bartlett. The accounts showed that during 1899 the Society had disbursed in sickness pay a larger amount than in any previous twelve months of its working. As the number of the members and their average age have grown year by year, the amount of sickness expected and provided for by the tables has necessarily grown with them. So far, the ever-increasing annual payments for sickness have always been within the expectation, and every year's account has shown a solid addition to the large pecuniary reserves of the Society. The committee had to regret the loss they have sustained through the death of Mr. H. R. Jennings, who has been auditor of the Society since it started in 1884. His successor will be elected by the members at the general meeting in May next. Prospectuses and all information on application to Mr. F. Addiscott, Secretary Medical Sickness and Accident Society, 33, Chancery Lane, London, W.C.

Another Dispensing Mishap.

DR. WILLIAM J. BELCHER, Medical Officer to the Bandon Workhouse, died on Saturday, the 29th ult, in consequence of his having accidentally swallowed carbolic acid by mistake for solution of magnesia, when mixing a draught for his own use. Medical aid was promptly summoned, but the unfortunate gentleman died before Dr. Reid arrived. Dr. Belcher, who was 62 years of age, belonged to an old Bandon family, and was extremely popular. He leaves a widow and several children to mourn his loss.

Deaths in the Profession.

THE death is announced of Dr. John Gardner Dudley, of Hove, Brighton, at the age of 71. Dr. Dudley took his degree at Cambridge in 1860 and was physician to

the Metropolitan Free Hospital for upwards of twenty-four years, afterwards being appointed consulting physician to the North London Consumption Hospital and other institutions. The death is also announced of Surgeon-Major Alexander Grant, at the age of 82, who saw a good deal of active service in Bengal, retiring in 1869. He was appointed honorary surgeon to the Queen in 1861. We have also to chronicle the death of Deputy-Surgeon-General David Cullen, who served in the Army Medical Department from 1854 to 1869. He was present at the siege and fall of Sebastopol, and during the Indian Mutiny he assisted at the capture of Lucknow.

The Sick and Wounded.

According to the *Times* an important scheme has now been completed on the Riviera by which practically all the leading hotels, besides many owners of villas, have agreed to receive as free guests convalescents from the Transvaal. Officers can obtain full information from the secretary, Transvaal Convalescents' Office, *Anglo-American Gazette*, Nice.

Munificent Bequests to Manchester Hospitals.

By the death of Mr. Gledhill, of Manchester, a director of Armstrong, Whitworth, and Co., the undermentioned medical charities have become recipients of the following:—The Southport Convalescent Hospital and Sea Bathing Infirmary, £2,000; the Huddersfield Infirmary, £1,000; Manchester Southern Hospital for Women and Children, £1,000; St. Mary's Hospital, Manchester, £1,000; Royal Eye Hospital, Manchester, £1,000; Hospital for Consumption in Manchester and Bowdon, £1,000; the Barnes Convalescent Home, £1,000; Ancoats Hospital and Ardwick and Ancoats Dispensary, £500; General Hospital and Dispensary for Sick Children, Pendlebury, £500; the Working Men's Christian Institution and Medical Mission Dispensary, Redbank, £500; St. John's Ambulance Association, Manchester Centre, £500; the Manchester and Salford Sick Poor and Private Nursing Institution, High Street, £250; the Openshaw Provident Dispensary, £250; Royal Albert Asylum for Idiots at Lancaster, £500; Northern Counties Hospital for Incurables, £500; Manchester Eye and Ear Hospital, £500; Manchester and Salford Lock Hospital, £250; and the Dispensary for Women and Children at Ancoats, £250.

PASS LISTS.

University of London.

AT the B. S. Examination for Honours in Surgery held last month, the following candidates passed:—

FIRST CLASS.

Bucknall, Thos. Rupt. H., M.D., London Hospital, Stevenson, Mabel G' (Gold Medal), Royal Free Hospital, Trotter, Wilfred B. L., M.D. (Scholarship and Gold Medal), University College, Turnbull, Jane Holland, Royal Free Hospital.

SECOND CLASS.

Turner, Philip, B.Sc., Guy's Hospital.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following candidates having passed the necessary examinations have been admitted Fellows of the College, their names being arranged in order of seniority of membership:—

Hugh James Moore Playfair, M.D. Lond., M.R.C.P. Lond., member July 31st, 1890; Herbert William Carson, L.R.C.P. Lond., member July 29th, 1895; Evan Lancing Evans, M.A., M.B., B.C. Camb., L.R.C.P. Lond., member November 14th, 1895; Percy Samuel Lelean, L.R.C.P. Lond., member November 14th, 1895; John Howell, M.B. Lond., L.R.C.P. Lond., member February 13th, 1896; William Francis Victor Bonney, M.D., B.S. Lond., L.R.C.P. Lond., May 14th, 1896; Thomas Rupert Hampden Bucknall, M.D. Lond., L.R.C.P. Lond., member August 4th, 1896; Wilfred Batten Lewis Trotter, M.D. Lond., L.R.C.P. Lond., member August 4th, 1896; Arthur Murray Cudmore, M.B., Ch.B. Adel., L.R.C.P. Lond., member November 12th, 1896; Charles Ralph Keyser, L.R.C.P. Lond., member August 4th, 1896; Gilbert Smith, M.B. Durham., L.R.C.P. Lond., member August 4th, 1896; Rodolph de Salis Stawell, B.A., M.B., B.C. Cantab., L.R.C.P. Lond., member August 4th, 1896; John William Thomson Walker, M.B., C.M. Edin., L.R.C.P. Lond., member August 4th, 1896; Herbert Mundy, L.R.C.P. Lond., member May 13th, 1897; Robert Gow Balston, M.B., C.M. Edin., L.R.C.P. Lond., member May 13th, 1897; Frank Mannington, L.R.C.P. Lond., member July 29th, 1897; Joseph Oliver Skevington, L.R.C.P. Lond., member February 10th, 1898; Edred Moss Corner, M.B., B.C. Cantab., M.A., B.Sc. Lond., L.R.C.P. Lond., member May 4th, 1898; Thomas Joseph Patrick Hartigan, L.R.C.P. Edin., member May 4th, 1898; John Law Adams, M.B., C.M. Aber., member November 10th, 1898; and Arthur Ferguson MacCallum, B.A., B.C. Camb., L.R.C.P. Lond., member November 10th, 1898.

Seventeen candidates were referred to their professional studies.

(a) "Cancer." By J. W. Nunn. Pp. 38. Henry J. Glaiser, London, 1899.

(b) "Enlargement of the Prostate: Its Treatment and Radical Cure." By C. Mansell Moulin. Second edition. Pp. 235. H. K. Lewis, 1899.

Notices to Correspondents, Short Letters, &c.

✎ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

LOCAL REPORTS AND NEWS.—Correspondents desirous of drawing attention to these are requested kindly to mark the newspapers when sending them to the Editor.

READING CASES.—Cloth board cases, gilt lettered, containing twenty-six strings for holding the numbers of THE MEDICAL PRESS and CIRCULAR, may now be had at either office of this journal, price 2s. 6d. These cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

ORIGINAL ARTICLES or LETTERS intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

REPRINTS.—Authors of papers requiring reprints in pamphlet form after they have appeared in these columns can have them, at half the usual cost, on application to the printers before the type is broken up.

COUNTY PRACTITIONER (Fyford).—Acetylene, even under existing circumstances, is a very economical and satisfactory method of illumination for dwellings far removed from a supply of coal gas. Experiments have shown that acetylene is only half as explosive and only a quarter as poisonous, as coal gas; indeed, for an escape to give rise to an explosion on the approach of a light the air must contain not less than 40 per cent. of the gas, an enormous proportion in view of its powerful odour. Acetylene attacks copper, for which reason brass fittings are disadvised, and the use of rubber tubing is dangerous to a degree.

N. B. O.—Great Britain stands second on the list of beer-drinking nations, with its 145 litres per head per annum, Belgium taking the first place with 170 litres, and Germany coming third with 116 litres. In France the quantity falls to 22.5. In Switzerland the figure is 55.

L.S.A.—Writes to ask whether, in view of the recent action of the General Medical Council, he is justified in calling himself physician and surgeon. To our mind he is, but we cannot accept the responsibility of advising him to use those titles. There is a house in a main street not a hundred miles from Harley Street itself, where a gentleman has on his brass plate "L.S.A.Lond., Medical Practitioner." It would tax the powers of any authorities to prosecute so ingenious and ingenious a gentleman. In that way lies safety.

WANTED, A REMEDY FOR ALOPECIA.

AN "old practitioner" asks what are the best remedies for alopecia in middle age with some greyness of hair and dandruff. From this scant description the case appears to be seborrhoeic. If so, the class of remedies, broadly speaking, that will be of service are of the stimulant and antiseptic class, e.g., cantharides and salicylic acid. Cleanliness is essential, together with careful attention to the general health.

RUS IN URBE (Yorks).—The preparation is a patent one. Its chief ingredients are two drugs in daily use in general practice, and there is absolutely no advantage in the advertised preparation over that which is made up according to a medical prescription. The cost of the protected compound is enormously disproportionate to its value. The name of the preparation is mentioned in a standard work on the diseases of the skin recently issued, and we are more than surprised that such should be the case.

Meetings of the Societies and Lectures.

WEDNESDAY, JANUARY 10TH.

HUNTERIAN SOCIETY.—8.30 p.m. Paper.—Dr. D. Grant: Cases illustrating various Conditions giving rise to Deafness (with demonstration of cases).

THURSDAY, JANUARY 11TH.

BRITISH GYNÆCOLOGICAL SOCIETY (20, Hanover Square, W.).—8 p.m. Specimens will be shown by Dr. A. Giles, Dr. Purcell, and Dr. F. Edge. Annual Meeting. Election of Officers, &c. President's Valedictory Address.

FRIDAY, JANUARY 12TH.

CLINICAL SOCIETY OF LONDON (20, Hanover Square, W.).—8.30 p.m. Clinical Evening. The following cases will be shown.—Mr. J. Hutchinson, jun.: Complete Sub-peritoneal Resection of the Oes Calcas.—Mr. Lunn: (1) A Case of Double Facial Diplegia in a Woman; (2) Congenital Luxation of the Right Hip in a Child, with Skiagraph; (3) Faroxysmal Hemoglobinuria in a girl of 10 years.—Mr. C. J. Symonds: Malignant Disease of the Thyroid after two Operations.—Mr. Jackson Clarke: Case of Excision of the Neck of the Lower Jaw for Ankylosis.—Other cases will be shown. Patients will be in attendance at 8 p.m.

BRITISH LARYNGOLOGICAL, RHINOLOGICAL, AND OTOLOGICAL ASSOCIATION (11, Chandos Street, Cavendish Square, W.).—4 p.m. Meeting.

Vacancies.

Brecon Infirmary, South Wales.—Resident House Surgeon, unmarried. Salary £90 per annum, with furnished apartments, board (all found except beer), attendance, fire, and gas.
County of Sutherland.—Medical Officer of Health for the County of Sutherland. Salary £300 per annum, and £50 in lieu of travelling and other expenses, with certain exceptions. Applications to the County Clerk, Golspie.
General Hospital, Nottingham.—House Surgeon for two years. Salary commencing at £100, with board, lodging, and washing.
General Infirmary at Leeds.—Resident Casualty Officer. Salary £100 a year, with board, lodging, and washing. Also House Physician for six months, board, lodging, and washing provided.
Glamorgan County Asylum, Bridgend.—Junior Assistant Medical Officer, unmarried. Salary £150, with board, apartments, washing, and attendance.
Metropolitan Asylums Board.—Assistant Medical Officer at the Imbecile Asylum at Caterham, Surrey, unmarried. Salary commencing at £120, with board, lodging, attendance, and washing. Apply to the Clerk to the Board, Norfolk Street, Strand, London. (See advt.)
Northampton General Infirmary.—Assistant House Surgeon, unmarried. Salary £100 per annum, with furnished apartments, board, attendance, and washing.
Parish of Gairloch, Ross-shire.—Medical Officer. Salary from the Parish Council £200 per annum, besides private practice. To reside at Poolewe. Apply to Mr. James Mackintosh, Inspector of Poor, Poolewe.
Three Counties Asylum, near Hitchin.—Second Assistant Medical Officer. Salary £150 per annum, with board, apartment, washing, and attendance. Unmarried. Apply to the Clerk, St. Neas Hunts.
Whitehaven and West Cumberland Infirmary, Whitehaven.—House Surgeon. Salary £120 per year, and £30 a year for dispensing, with furnished apartments and attendance.

Appointments.

HARVEY, B.A. Cantab., M.B., C.M.E.D., Resident Medical Officer to the Hertford British Hospital, Paris.
BAUMANN, E. P., M.B. Edin. M.R.C.S.Eng., House Surgeon to the Glasgow Maternity Hospital.
BUCKLEY, L.S.A. Medical Officer for the Hasland Sanitary District of the Chesterfield, Derby, Union.
BROWN, ALFRED, M.D., M.R.C.P., Honorary Physician to St. John's Hospital for Diseases of the Skin, London.
GILES, ARTHUR E., M.D., B.Sc.Lond., M.B., B.Ch.Vict., F.R.C.S., Edin., M.F.P.P.Lond., Gynaecologist to the Tottenham Hospital.
HARRIS-JONES, E., M.B., C.M.E.D., Resident Surgical Officer to the Birmingham and Midland Eye Hospital.
JOHNSON, P., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., Medical Officer of Health for the Borough of Stoke-on-Trent.
LAWSON, T. C., M.R.C.S., Medical Officer and Public Vaccinator for the Longtown Sanitary District of the Longtown Union.
PEARCE, F. H., L.R.C.P.Lond., M.R.C.S., Senior Assistant Medical Officer for the Workhouse, Bradford.
ROCHE, T. F., L.R.C.P., F.R.C.S. Edin., L.F.P.S. Glasg., Medical Officer for the Penarth Sanitary District.
SAVILLE, THOMAS, M.D., M.R.C.P., Honorary Physician to St. John's Hospital for Diseases of the Skin, London.
SEACOMBE, A. F., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., Resident Medical Officer of the Workhouse, Toxteth, Liverpool.
UNDERHILL, S. Y. H., L.R.C.P., M.R.C.S., House Surgeon to the Suffolk General Hospital at Bury St. Edmunds.

Births.

COSENS.—On January 3rd, at 49, Oxford Terrace, London, W., the wife of C. H. Cosens, M.R.C.S., L.R.C.P., of a daughter.
DOW.—On January 4th, at High Street, Lewes, Sussex, the wife of William A. Dow, M.D., of a daughter.

Marriages.

MANNINGTON—CLARKE.—On January 4th, at Hawkhurst, Frank Mannington, F.R.C.S., of Muswell Hill, to Lillian, second daughter of E. R. Clarke, of Hawkhurst.
MEAKIN—BALL.—On January 6th, at St. Giles's Church, Cambridge, Harold B. Meakin, M.D., Indian Medical Service, to Frances Amelia, elder daughter of Sir Robert Ball, Observatory, Cambridge.
WATSON—BARRETT.—On January 3rd, at Norwich Cathedral, Charles E. Watson, M.D. Brux., M.R.C.S.Eng., of Tunbridge Wells, to Grace Elepheth, daughter of Rev. Canon Barrett, of Lincoln.
WRIGHT—NORRISH.—On January 4th, at the Parish Church, Crediton, Samuel B. Wright, L.R.C.P., M.R.C.S., of Romford, Essex, to Annie Jane, daughter of D. M. Norrish, Esq., of Fowton, Crediton.

Deaths.

DUDLEY.—On January 2nd, at 63, Hova Villas, Brighton, John Gardner Dudley, M.A. M.D., M.R.C.P., formerly of 71, Belgrave Road, London, aged 72.
TAYLOR.—On January 6th, at Mattishall, Norfolk, George Taylor, M.R.C.S., J.P., aged 82 years.

EXCISION OF THE VESICULÆ SEMINALES FOR TUBERCULOUS DISEASE. (a)

By C. MANSELL MOULLIN, F.R.C.S.,

Surgeon and Lecturer on Surgery to the London Hospital, &c.

IN discussing the question of the operative treatment of the early stages of tuberculous disease of the bladder during the last session of the Medical Society, I suggested that, if in any case in which the disease was limited to one side, it seemed probable that the infection was spreading upwards from the epididymis to the vesicula seminalis, it would be advisable to remove this organ as well as the testis, and in this way prevent, or at the least lessen the chances of, the extension of the tubercle to the prostate and the base of the bladder. I had before then removed one of the vesiculæ for chronic inflammation consequent upon gonorrhœa, and satisfied myself that the operation presented no exceptional difficulty, but I had not then met with a case of tuberculous disease in which such a proceeding as this appeared to me to be suitable. Since then I have performed this operation twice with this object, and the result in each case has been excellent, the patient making a good recovery, and, to all appearance being freed from a source of infection which, if left, would have extended to the bladder and caused intense suffering and death.

One of these cases was at hospital. The patient was twenty-two years of age. Last Easter he noticed that the left testicle was becoming enlarged and painful. Three weeks before admission the skin of the scrotum had given way. On admission there was advanced tuberculous disease of the epididymis with a sinus in the scrotum. The vas deferens was thickened and the vesicula seminalis of the same side hard and nodular. There did not appear to be any tuberculous disease elsewhere. The testis was removed on July 4th. An oval incision was made in the scrotum so as to include all the involved tissues, and continued up the groin. The inguinal canal was laid open, the cord ligatured at its highest accessible point, the whole mass removed, and the wound sutured. The patient was then placed in the lithotomy position with the buttocks very much raised, and the under surface of the prostate exposed through the perineum by means of a modification of Zuckerkandl's incision. This consists of a transverse division of the perineum through or immediately behind the centrum tendineum, with a prolongation from each end backwards and slightly inwards into the ischio-rectal fossa, so far as may be found necessary. Instead of this I made a semilunar incision with the concavity towards the anus. This divides the super-

ficial perineal vessels and nerves, but avoids any danger to the artery to the bulb unless this takes some unusual course. If more room is wanted the backward prolongation on the affected side can be made rather longer, but I have not found this necessary. The external sphincter is detached; the rectum pressed down into the concavity of the sacrum, and the fibres of the levator prostatae divided. All that then remains is the layer of the recto-vesical fascia which passes behind the vesiculæ seminales, and keeps them against the posterior surface of the bladder. I have not found any difficulty with the prostatic plexus. If the division of this fascia is made in the middle line above, or on a level with the upper limit of the prostate, there is little or no fear of injuring it, at least, in young subjects. If now, firm pressure is made over the pubes by an assistant, the prostate, the posterior surface of the bladder, and the vesiculæ seminales are brought within easy reach of the finger, and can be manipulated without difficulty. It is better that the bladder should not contain any urine, and I have not found any benefit from a catheter tied in the urethra.

In the present instance the vesicula was separated from the under surface of the bladder, hooked well forward, and the vas deferens divided as high up as possible. In doing so the ejaculatory duct was torn out from the prostatic urethra, laying this open. The slit in the urethra was sutured with catgut; the wound plugged with iodoform gauze to prevent any venous oozing, and the sphincter ani united to the centrum tendineum by a silk-worm gut suture. The superficial wound was closed with catgut. There was very slight shock. The temperature rose on one occasion to 101 degs. F., but soon fell again. At first, the urine came almost entirely through the wound. A fortnight after the operation he passed twenty-five ounces through the urethra, and after this it nearly all came the right way, but there is still a small fistula through which a few drops exude during micturition. The bowels were opened by enema five days after the operation, and there was never any loss of control over the sphincter. The part removed included the whole of the vesicula seminalis with the dilated portion of the vas deferens. The interior was full of breaking down caseous masses, but the disease did not appear to have penetrated through the wall, or to have involved the cellular tissue around.

The other case resembled this one so closely in all material particulars that there is no occasion to give a separate description. The epididymis was large and hard, but the caseous deposit had not yet broken down, so that there was no occasion to excise any portion of the scrotum. Two modifications were made in the method of operating. One was the removal of the whole of the vas deferens, part of which in the former case had been left behind. Two ligatures were used in the preliminary castration, one for the vas by itself, the other to include the other

(a) Paper read before the Medical Society of London, Monday, January 8th, 1900.

structures in the cord, and the vas was separated from its surroundings so far as it could be through the internal abdominal ring. The same was done for its lower end where the vesicula had been exposed through the perineal opening, and by careful traction the whole of the remaining portion of the vas was withdrawn together with the vesicula. The other modification was the placing of a ligature around the ejaculatory duct to prevent any escape of urine into the wound. In the first case I question whether this would have been feasible owing to the extent to which the vesicula was affected. In this one it succeeded in so far that the wound closed up without any trouble after the packing had been removed. The disease was of the same character, but hardly so far advanced as in the former case. Recovery was uneventful.

This operation does not appear to have been performed upon many occasions, and in the majority of these the immediate cause appears to have been induration and persistent pain consequent upon gonorrhoeal inflammation. I can find very few cases recorded, none in England, in which it has been done for tuberculous disease, although there are a few in which caseous deposits have been scraped out. Ullman on one occasion removed both vesiculae for tubercle; and in this case, as in the first one of mine, the ejaculatory duct was divided in the substance of the prostate, and a small fistula persisted. Roux has operated twice, and Fenger, Schede, and one or two others each once. Zuckerkandl's incision, or the modification of it which I adopted, appears to me to be by far the best. Roux recommends a lateral incision on the affected side, two or three centimetres from the middle line, reaching as far back as the ischium, and exposing the rectum freely. The patient is placed in the lithotomy position, but lying upon the side rather than upon the back. Pressure exerted from the rectum is made use of for the purpose of bringing the upper edge of the vesicula into the wound. But the small size, and the great depth of the wound makes access very difficult. Von Dittel's incision which follows the same direction, but begins with a curve in front of the anus, gives more space. But unless the perineum is very deep, or the suprapubic region very rigid, neither of which is probable in young subjects affected with tuberculous disease, there is no difficulty in exposing the part thoroughly through Zuckerkandl's; and this has the further advantage that if there is any question about the condition of the other vesicle, it can be examined without difficulty.

I do not suppose that this operation will be often performed. A fair number of cases of primary tuberculous disease of the vesiculae seminales has been recorded, and these, of course, would be the most suited to an operation of this kind, but it is probable they are not nearly so common as the number of those which have been published would imply. And the operation is not required when the disease is limited to the epididymis, and is almost useless when it has extended beyond the vesiculae and invaded the surrounding structures. A portion of the prostate has, it is true, been excised at the same time in one instance, and in another a caseous focus was felt and scraped out; but this must be nearly the limit. There remain, however, a considerable number of cases in which, at a certain stage, the disease has extended into the vas, but has not yet involved the prostate to any serious extent, or the base of the bladder; and these cases can be diagnosed with a very fair degree of certainty, for the existence of tuberculous deposit in the vesiculae can be felt without any difficulty through the rectum; in such as these I believe this operation to be not only justifiable, but strongly to be recom-

mended and even to be urged, provided, of course, the lungs and other organs are not seriously involved. Without exposing the patient to too great a risk it gives him one more chance of being freed from a disease which, when it has once reached this stage, will, if it is left to itself, inevitably progress and ultimately cause death with the greatest suffering.

NOTES ON RECENT CASES OF ENTEROPTOSIS. (a)

By A. A. SYMONS ECCLES, M.B.

THE four following cases have been selected from twenty-two examples of enteroptosis recorded in my note-book for 1899, because they illustrate very definitely the causes and effects of Glénard's disease, (b) corresponding closely to the typical conditions described by the French physician who has given us the first and best account of a malady which has not received the attention and serious consideration in this country it appears to me to demand.

The two first cases belong to the class which has been by far the most numerous in my own practice, the sufferers having passed through the stages of (1) simple dyspepsia without local abdominal physical signs, (2) difficult or disordered digestion with the local signs of enteroptosis, and (3) the neurasthenic symptoms consequent thereon. The other two cases are also briefly noted, as they seem to come under the category of primary enteroptosis not preceded by dyspepsia without downward displacement. In regard to the first two cases it may not be easy to insist on the absence of enteroptosis at the outset; but looking to the history and sequence of symptoms it may be fairly stated that evidence of any downward displacement of viscera is in these and similar instances not forthcoming till after a certain period has elapsed.

CASE I.—Mrs. —, æt. 39, was sent to me early in the summer by Professor Clifford Allbutt, who had diagnosed the existence of enteroptosis and enjoined the recommendation that the patient should not be informed of the local conditions. For more than eighteen months there had been gradually failing health with increasing neurasthenia, preceded by epigastric distension, acid eructations shortly after meals, and tasteless flatulence immediately on taking food.

The appetite had been good, but the discomfort following meals had led to restriction of diet as when the stomach was empty no discomfort was felt. Gradually, however, and more especially during the past twelve months the symptoms had altered in character, for in addition to the immediate expulsion of gas when food was taken, there followed some two or three hours after meals a sense of weight and oppression of the epigastrium with dragging pain in the back, and an intolerable feeling of inertness sometimes relieved after gurgling or flatulence.

The indigestion would sometimes pass away quickly, at others the heaviness lasted till the next meal, when for a time varying from half-an-hour to two hours some ease was obtained only to be followed by another bout of discomfort always accompanied by great weariness. Meanwhile the bowels, which had previously acted regularly, became more relaxed, and for a time there was diarrhoea, alternating with scybalous motions.

Headache, vertical and occipital, asthenopia, insomnia due to flatulence, and various neurasthenic symptoms, with loss of weight and strength, rapidly

(a) Read before the Chelsea Clinical Society, December 19th, 1899.
(b) "Application de la Méthode Naturelle l'Analyse de la Dyspepsie Nerveuse. Détermination d'une espèce." Frantz Glénard, *Lyon Medical*. Vol. 48, 1885. P. 449 et seq.

becoming worse in the three months preceding the date on which I received this patient for treatment, brought her under my observation when all the symptoms recorded above were present with the physical signs of enteroptosis. The epigastric region was scaphoid with little, if any, bulging of the flanks or hypogastrium. A distinct splashing sound could be elicited on palpation over the epigastrium from the level of the seventh left costa in the mammary line across to the inner edge of the right ninth costal cartilage, thence downwards to the level of the navel and upwards to the left hypochondrium again. With the stethoscope in the seventh left interspace just inside the mammary line, the wave could be distinctly heard and felt when the hand was pressed gently upwards against the greater curvature of the stomach lying just below the navel. The right kidney was freely movable, on deep inspiration occupying the position shown in the diagram.

CASE I.—DIAGRAM I.

CASE I.—DIAGRAM II.

Examination per rectum revealed the existence of sigmoid prolapse, a distinct protrusion of the pelvic loop into the rectum being felt when the patient strained, and through the anterior rectal wall small globular faecal masses could be recognised lying in the flaccid bowel. For some time this patient had suffered from enuresis, varying in severity, and until the relief of the enteroptosis was accomplished frequent micturition night and day prevented her from obtaining rest.

The position of the viscera as described refers to the recumbent attitude; their further down-dropping is shown in diagram II, when the patient assumed the vertical or standing posture.

At the conclusion of five weeks treatment the weight had risen from 7 st. 3 lbs. on admission to 8 st. 5½ lbs., and the organs were no longer dislocated downwards. Only the lower third of the right kidney could be felt on deep inspiration, and the stomach lay well above the navel. One further remark may be made on this case. There was marked low tension, the pulse was 96 at first, then 84, small and easily compressible until the third week of treatment, when it gradually increased in tone and volume, the rate in the recumbent position being reduced to 70, and never rising more than 14 beats per minute on the assumption of the erect position. The patient was furnished with a hypogastric belt on leaving my care. I have heard within the past few days of her good health and spirits.

CASE II.—Miss —, æt. 60, was sent to me by Dr. Shann, of Lowestoft, complaining of depression, gloom and prostration, everything that happened being felt in the stomach. Indigestion with great distension and flatulence occurs two hours after each meal and follows directly on any emotion or fatigue.

This has continued for many years, and has become much worse for the last two years. The tongue was flabby and coated with pale fur. The appetite was nil, and food had been reduced to a very small quantity, on account of the flatulence, dragging and gnawing pain through to the back, and the intolerable sense of weight in the epigastrium, followed by constant unrest and irregular localised distension of the bowels whenever food was taken.

Epigastric pulsation, and "a sensation of everything being blocked," also caused great distress. The bowels were only relieved by the use of aperient, glycerine suppositories, and enemata.

The abdomen was thin walled, and very flabby, with marked protrusion of the hypogastrium and hollowness of the epigastrium, greatly exaggerated when the patient stood up.

On palpation the aortic pulsation was easily felt between the xiphoid cartilage and the navel, just above the umbilicus a firm thick cord could be felt crossing from the left to the right hypochondrium.

DIAGRAM III.

Below the navel and occupying the position shown in the diagram the splash sound was very easily elicited; by percussion and ausculto-palpation the limits of the stomach were found to be enlarged and displaced downwards, especially to the left. The right kidney was freely movable, the left could also be felt more than normally on deep inspiration. Examination per rectum revealed a roomy bowel with great redundancy of the mucous membrane, which hung in loose folds and made it difficult to reach the entrance to the sigmoid flexure. Subsequent examination proved the existence of some degree of entero-stenosis here as in the transverse colon.

The heart sounds were excellent; but with a splendid ventricle the pulse was low. Extremities cold. There were rûles at both bases. Sleep was good for the first part of the night, but the patient always awakened at, or about, 2 a.m., and obtained no sleep later.

Previous illnesses.—Acute gastritis at the age of fourteen, between the ages of seventeen and nineteen constant gastric disturbance and emaciation followed ever since by chronic invalidism due to failure of digestive powers. An operation by Mr. Allingham for prolapsus ani, had greatly improved the bowel troubles, but constipation still existed.

Here then is a typical case of Glenard's disease, gastritis, dyspepsia, presumably, without local physical signs followed by emaciation, marked evidence of enteroptosis, entero-stenosis, and as a consequence nervous and muscular prostration.

This lady had not given way to her digestive troubles; for many years she drove, rode, and walked,

suffered much disappointment, but throughout maintained a brave and buoyant disposition, until the loss of rest, caused by conscious digestion and all the evils of malnutrition, so affected her life that she was anxious to carry out the wishes of her medical adviser and come under my care for treatment which has not yet concluded; but so far, I may say, sleep is more lasting at night and rarely less than six hours' in duration with a short interval of awakening. The sense of stoppage no longer is felt, though the atony of the stomach and bowels still makes of digestion a conscious effort. A daily motion is obtained with the use of a diluted glycerine injection. There is no longer any pain or gnawing in the epigastrium, nor is there any depression of spirits.

The abdomen is more normal in the shape and texture of the walls, and the stomach now shows that it is capable of contracting on its contents, while the intestines, though feeble and slow in their peristaltic action, no longer fail to impel matters which formerly could be felt accumulating in the transverse, descending, and pelvic colon. Very little weight has been gained, but there is decided increase in vigour and vitality.

The next two cases are examples of primary enteroptosis.

CASE III.—Miss —, æt. 26, was recommended to consult me by Dr. P. S. Abraham, under whose care she was for a skin affection. My friend, Dr. Abraham, had diagnosed right nephroptosis, and when we saw his patient together he agreed with me that there was also gastroptosis and left nephroptosis. When this lady came under my close observation in the early part of this year it was plain to see that enterostenosis existed at the hepatic and splenic flexures of the colon, and I could sometimes feel the transverse colon on deep pressure in the situation depicted in the diagram. The patient complained of pain in the left lumbar region and in the umbilical region, also over the ninth and tenth dorsal vertebræ and the corresponding left ribs. This pain came on from an hour to three hours after meals and when very tired, as she always felt in the afternoon, it was most severe.

DIAGRAM IV.

When she starved she was comfortable. She first noticed the pain suddenly in the left side "like a violent stitch in the side, which doubled her up" while climbing in a mountainous district, and for six months a pain like toothache in the left side and back, becoming worse in the last month, obliged her to give up the gymnastic exercises she had previously enjoyed.

The appetite was voracious; but distension pain and nausea about two hours after meals had compelled her to suffer hunger rather than the pain produced by food; though at first the discomfort so long

after meals did not seem to be caused by what she had eaten. The bowels had been constipated since the pain began. Now she felt weak and depressed and had lost 11 lbs. in five months. Of this weight she regained 7 lbs. in four weeks, and with a well-fitting belt is quite free from local discomfort, the pain and constipation no longer troubling her.

CASE IV.—Mr. C., æt. 29. Complains of a dragging sensation in the back, with a feeling of always having a weight in his stomach, which is also the seat of a gnawing pain and flatulent distension. Immediately on taking food eructations arise, and two and a half hours after any food there are sour regurgitations. The stomach is enlarged and has fallen downwards to the left of the navel. There is obstinate constipation, inability to digest cellulose, acetic, and butyric acids have been found in the matters regurgitated. No vomiting has occurred. This condition of affairs came on suddenly one afternoon after a great shock. The appetite has been good throughout the two years since the difficulty in digestion arose; but he is losing weight, and is anæmic.

The first sound of the heart is feeble, and inaudible in the recumbent posture.

The diagram shows the position of the stomach in the recumbent and erect position.

DIAGRAM V.

For the patient I ordered a belt, and saw him again last month, after the lapse of a few weeks, the physical signs and subjective symptoms of gastroptosis, and atonic enlargement are still present as before; but the patient has gained six lbs. in weight.

These four cases illustrate fairly well what may be regarded as conditions of difficult digestion due to displacement.

Cases I. and III. were treated by rest, uptilting diet and manipulation, a belt being worn since in order to maintain the organs by upholding the hypogastrium. The second case is still under treatment, and the fourth will probably need to have the abdominal pressure restored by the replacement of packing material and the improvement in quantity and quality of the abdominal muscles, for unless this is accomplished the ill effects of enteroptosis cannot be overcome.

WE are asked to announce the Committee of Management of the Royal Orthopædic Hospital have offered to place two wards (containing ten beds) at the disposal of the War Office for the reception and treatment of soldiers wounded in the South African campaign.

The Harben Lectures.

DIPHTHERIA.

By PROFESSOR WILLIAM R. SMITH, M.D., D.Sc.,
F.R.S.Ed., BARRISTER-AT-LAW,

ABSTRACT OF LECTURE II.

In the present day only such diseases are considered infective as are produced by a living organism entering the body from without, and capable of multiplication within. A disease caused by a substance not capable of multiplication within, such as a chemical body, is spoken of as an "intoxicative" process. In such infectious diseases as diphtheria, anthrax, or tetanus, we have a combination of these two causes—viz., the mechanical presence of a scientific organism, and the metabolic products of the life of such; indeed, the general rule of an infective process due to a vegetable micro-organism, is that the principal lesions are occasioned, not directly by the organisms, but indirectly by such organisms consequent upon the metabolic products of their growth.

Sometimes the organisms produce mechanical disturbances either locally or generally, which are likely to materially modify the symptoms caused by the toxins. The intoxication may be local or general, examples of which are found, of the one in some forms of suppuration, and of the other in diphtheria.

Closely associated with this aspect of the subject is the question of predisposition or susceptibility to disease. This may be either natural or acquired.

We know that animals possessing the power of resistance to the contraction of certain diseases may be rendered susceptible by the adoption of certain measures; e.g., pigeons and hens, which are naturally resistant to anthrax, can be rendered susceptible by starvation, whilst white rats do not in this way lose their immunity. The deprivation of water will also render dogs, hens, pigeons, and other animals susceptible to anthrax. Again, fatigue, loss of blood, an unsuitable diet, exposure to heat, cold, or damp, are also capable of removing the natural immunity of animals, and what is true of individuals is also true of races.

Age also is an important factor. I shall have to show presently that in diphtheria the child is more susceptible than the adult. Closely allied with the subject of predisposition and natural resistance or immunity is that of acquired immunity. If a person has suffered from an infectious disease, he is more or less protected against a second attack. In some cases the immunity is permanent, as with small-pox, whooping-cough, &c.; in others it is transient, as with diphtheria. In the laboratory immunity may be produced by inoculation either with an attenuated virus or small doses of living and fully virulent organisms, or thirdly, with the metabolic products or toxins of living bacteria. For this chemical vaccination either small doses of the virulent poison or of the attenuated toxins are used, and by repeated inoculation the animal is accustomed to withstand larger doses.

Further experiments on this most interesting subject resulted in the proposition established by Behring that, "if an animal has been artificially protected against a particular infective agent, its blood or serum acquires the power when injected into another animal of directly transmitting an immunity from that agent"; e.g., the blood serum of animals artificially protected against diphtheria has the power of protecting susceptible animals both from infection by the diphtheria bacillus and from its toxin. It was further shown by Behring that the protective serum can exert this marvellous power even after infection has taken place, when the symptoms of infection or intoxication have set in, and consequently such serum is not only protective, but curative. It is obvious, however, that in this latter case larger doses of the serum and promptness in its application are desirable. If immunity be obtained by injections of the bacilli or its toxins, it is only subsequent to a struggle on the part of the animal with the disease. On the

other hand, if serum be injected, the part played by the animal is a passive one, there being no struggle whilst the immunity-conferring substance circulates through its tissues. Thus we have, according to Ehrlich, active and passive immunity.

There are several points in connection with the etiology of diphtheria which we shall now do well to study. We find, for instance, that the disease is most prevalent in London in the latter half of the year, and particularly in the last four months. Another interesting fact in connection with the age incidence is that the two sexes are differently affected at the same age-periods by diphtheria. In the first year of life boys are much more liable than girls to die of the disease; but this extra liability diminishes year by year, and in the third or fourth year it is transferred to the female side. This is true both in London and in other parts of the country.

In London, however, the maximum male mortality is at age one, the female mortality steadily increasing for the next two years, whilst in the remainder of the country a maximum is reached for both sexes at age three. But London and the remainder of the country are alike in this, that more females than males die from diphtheria at age three, and many more in the age-group 5 to 10. It might be thought that these differences could be accounted for by the facts:—(1) That more males than females are born; and (2) that the general mortality among males is greater year by year than that among females. Thus the excess of male mortality in the earlier years might be accounted for by the larger number born, and the excess of female mortality in the later years by the larger number of survivors. Reference to the Census report shows, however, that this explanation is inadequate. After making due allowance for the different numbers of the two sexes living at each age, we find that in London the female mortality from diphtheria under one year of age is 86·8 per cent. of the mortality among an equal number of males at the same age. The percentage increases year by year, until at ages 2 and 3 the mortality of the two sexes is practically equal. After this the female mortality is in excess, being 30 per cent. more than the male mortality in the age-period 5 to 10. In the remainder of England and Wales the female mortality is only 77·6 per cent. of the male mortality under one year of age; but, as in London, the percentage increases year by year, except for a small irregularity at age 4, and the excess at age 5 to 10 is strongly marked, although it is not so great as in the case of London.

The age period 5 to 10 may be taken as very fairly representing school age; and any explanation of the incidence of diphtheria in London must deal with the fact that at this age girls are *one-third* more liable to die of diphtheria than are boys. It is hardly suggested by anyone that school aggregation increases the amount of diphtheria by so much as one-third; but here there is direct evidence of some influence or condition which either affects girls only, raising their diphtheria mortality by one-third, or else affects girls more than boys, raising the mortality of both, but raising that of girls enormously more than that of boys. No difference of the school conditions of the two sexes can be imagined which would yield even a plausible explanation. The cause must be sought among conditions affecting boys and girls in different ways or to a different extent, *outside* the schools.

It is interesting to notice that the same rule holds good when we consider notifications in London, the only difference being that the year of transference is in most cases a year earlier.

To test the incidence of diphtheria on children of various ages in London (apart from the mortality, which is compounded of the incidence and the case-mortality the latter of which may possibly vary largely at different ages) the actual notifications of the disease were ascertained for as many years as possible, in separate years of age up to 10 years, and for the ages 10 to 15 in one group. Unfortunately, the ages were so imperfectly returned in the years prior to 1892, as to make the figures useless for any purpose of comparison. In 1892, 1893, and 1894, however, the ages were stated in 95 per cent., 97 per

cent., and 98½ per cent. of the cases respectively, and since that time, 1895-98, they have each year been above 99 per cent. By assuming that the small residuum of unnoted ages in each year should be divided out in the same proportions as the stated ages, a very close approximation to the truth is obtained.

The next process was to estimate the number of children of each age living in London in each year. The number of children at each age between 5 and 10 was calculated by interpolation by the method of finite differences, and the corresponding numbers living in each year since 1891 were estimated on the assumptions: (1) That the increase of population has been at the same rate since 1891 as between the censuses of 1891 and 1896; and (2) that the proportion of children of each age in the total population has remained the same as at the Census of 1891.

The population and notifications thus ascertained were then placed side by side, and the number of notified attacks of diphtheria per 1,000 living at each age was calculated.

Statistics thus compiled show that the greatest attack rate is generally at age 4 to 5; the next that the attack rates are nearly equal for the 3 years of age 3 to 4, 4 to 5, and 5 to 6, and that on each side of this period of 3 years the rates fall considerably. A closer examination shows that infants under 1 year of age are remarkably exempt, their rates being on the average only about two-thirds of the rates for children between 10 and 15 years of age, and less than one-fifth of the rates at age 4 to 5. This exemption, however, appears to cease on completion of the first year of life. If the notification returns may be trusted, the liability to diphtheria is three times as great among children between 1 and 2 years of age, and four times as great among children between 2 and 3 years of age, as it is among infants in their first year. A possible explanation of this remarkable difference is that diphtheria is often spread by children sleeping together, and that young infants, by sleeping with their parents, escape this source of infection.

Direct infection from person to person is probably by far the most common cause of diphtheria, and it will be easy to understand that the presence of the organism in the throat of a discharged patient, or in an adult where but little trouble arises since his power of resistance is great, might under favourable conditions for transmission be a fruitful source of the disease.

Milk is undoubtedly a vehicle of diphtheria, and outbreaks of the disease have been frequently traced to this source; but the disease does not appear to have any direct relation to defective sanitary conditions, although such conditions may lower the general power of resistance, and give rise to throat complaints, which would provide a favourable soil for the bacillus to thrive upon if it should obtain access. In the same way dampness of the soil, or of houses might predispose to the disease.

But of all conditions which exert an influence upon the spread of the disease, that of school attendance is supposed by many to be by far the most powerful and far-reaching. Let us look into this a little more closely.

Whilst there are objections to receiving death-rates as evidence of the prevalence of a disease, yet these are the only figures on the subject available for purposes of comparison, with the exception of London, where, owing to the notification system, far more valuable evidence is obtained from a consideration of the actual number of cases of illness.

Moreover, in the case of Dresden, Leipzig, and Vienna, it is impossible to obtain the age-distribution of the inhabitants. Consequently, in order to make use of the figures supplied, it was necessary to assume that the age-distribution of each city was similar to that of London.

Taking the figures thus obtained for what they are worth, it will be seen that the period of life on which diphtheria falls most heavily is during the first few years, and in this respect the result tallies closely with the figures obtained by more reliable methods for London. The years of greatest mortality in Dresden are the second, third, and fourth; in Leipzig the second, third, fourth, and fifth; and in Vienna the second and third; while in none of these towns is education com-

pulsory till the sixth year, by which time the mortality has dropped considerably. Consequently, in spite of the assumption mentioned above, the above figures are probably not very far from the mark, and it can be safely asserted that in these towns at least the chief risk of infection occurs previous to the school age.

From Paris, Copenhagen, and Venice the returns are not so full, but in each case the age of maximum mortality is considerably earlier than the minimum age of compulsory school attendance.

The opinions regarding the influence of compulsory school attendance on the spread of diphtheria, which have been formed by the various authorities above enumerated, differ considerably in the different localities. On reading through their statements, however, the impression obtained is that the majority consider attendance at school to be an unimportant factor in the spread of the disease; that it undoubtedly plays a small part, but no greater than would occur wherever social intercourse can take place; and, more important still, that closure of schools and abolition of compulsory education would not stamp out the disease.

It has been stated by Mr. Shirley Murphy that "the diphtheria mortality at ages 3 to 10 years did not fall in 1871-80 in anything like the same degree as the diphtheria mortality at all ages"; that "this new departure is most notable in London"; that "it is suggestive of a fresh factor of diphtheria at ages 3 to 10 years becoming operative in the decennium 1871-80"; and that "as regards England and Wales and London in 1881-90, as compared with 1861-70, the special incidence on the age 3 to 10 years is practically maintained."

Now it may at once be freely admitted that if it were true to say—

(a) That children aged 3 to 10 years attend school, and children under 3 years do not;

(b) Further, that diphtheria has of late years increased among children aged 3 to 10 years, whilst children under 3 years of age have been comparatively exempt—

then undoubtedly there would be a very strong presumption that school attendance is the chief cause of the increased incidence of the disease. But are these statements correct? In order to test this, it is not enough to begin by grouping the facts under the ages 0 to 3 and 3 to 10; it is necessary to ascertain what is the age-grouping under on which each set of facts most naturally falls. For instance, if it were found that the age of school attendance practically begins at 4 years, and that the special liability to diphtheria begins at 2 years, there could be hardly a doubt that the two things are independent. In such a case, the age-grouping 0 to 3 and 3 to 10 would only suggest false conclusions.

The average number of children in London living at age 3 to 4 may be taken as about 143,000; so, obviously, a very small proportion of children at this age are subject to the risk of school infection, and it is more correct to speak of 4 years instead of 3 years as the age at which school attendance commences. We should, therefore, expect that any tendency to school infection would show itself in a marked manner at age 4.

If we consider the diphtheria notifications per 1,000 living at ages under 15, it is seen that the greatest number of attacks take place between the ages of 3 and 6, and that there is a marked drop after this age.

The same argument which has been used above in respect of the increase or decrease of diphtheria mortality at particular ages in successive periods of time is applicable to these notification rates, viz., if it can be said (1) that children above a certain age attend school, while those below that age do not; (2) that children above that age are specially subject to diphtheria, while those below it are comparatively exempt—then there will be a strong presumption that school attendance is the main factor in the spread of the disease.

Very slight scrutiny of the returns shows at once that the conditions just suggested do not exist. It is true that the notifications reach their maximum at ages 3 to 5, the first years in which any appreciable number of children attend school; but they reach the maximum, be it noted, by a steady yearly rise through the anti-school period of life.

At the age 4 to 5, although there are more than twice as many children attending school as between 3 and 4, yet the number of attacks is practically the same at the two periods; while from 5 to 6 the school-attending children are more than three-and-a-half times as numerous as at the age 3 to 4. That is to say, greatly increased numbers of children are subjected to the risks of school infection, and yet the number of attacks is either the same or shows a decline.

Moreover, we find that the attacks at age 1 to 2 were nearly three times as many as in the first year of life. At age 2 to 3 they were 31.5 per cent. more than at age 1 to 2; and at age 3 to 4 they were 26.4 per cent. more than at age 2 to 3. Thus the *proportional increase* was less in the first year of nominal school life than in the year immediately preceding it. In the next year of age—4 to 5 years—an increase of 129 per cent. in the children attending school is accompanied by an increase of only .3 per cent. in the diphtheria attacks; and at the age 5 to 6 a further increase of 55.7 per cent. in the children attending school is accompanied by a decrease of 6.5 per cent. in the diphtheria attacks.

Stronger evidence could hardly be adduced that age-susceptibility is the main factor in the selection of the victims of diphtheria, and that, at the most, school aggregation acts only as a slightly disturbing element. It appears reasonable to suppose that if there were no school attendance at all, the increase of attacks at age 3 to 4 over age 2 to 3 might be somewhat less than 26 per cent., and that the decrease in subsequent years might be somewhat more rapid than it actually is. But this is only another way of saying that diphtheria is sometimes communicated at school; the age-incidence would probably be altered to a much greater extent if children were prevented from playing together out of school. Such suggestions are, however, entirely hypothetical. But it is a fact that a child becomes *more* liable to be attacked by diphtheria year by year as it approaches school age, and becomes *less* liable year by year after it has reached school age.

From the facts represented in these diagrams it is impossible to resist the conclusion that no *special increase of liability* to diphtheria can be traced to the beginning of school attendance. In fact, the ages which are now the most subject to the disease would still be the most subject if aggregation in schools were abolished altogether.

Taking the notifications at each age, for the four weeks preceding the holidays in 1895, i.e., the four weeks ending August 3rd—for school-influence would naturally be manifested for some days after the closure of the school—and comparing them with the notifications during the four weeks of holiday, i.e., the four weeks ending August 31st, and also with those of the four weeks after the holiday, i.e., the four weeks ending September 28th, we get the following table:—

Notifications in London at each age for the four weeks before, during, and after the holidays in August 1895.

Four weeks ending—	0	1	2	3	4	5	6	7
August 3 ...	33	66	82	116	119	103	81	65
August 31 ...	18	59	59	74	71	57	62	39
September 28	25	56	73	114	109	86	92	71
	8	9	10	11	12	13 to 15	15 and upwards	
August 3 ...	54	48	34	20	30	48	228	
August 31 ...	30	31	31	19	13	35	201	
September 28	46	39	44	23	24	40	233	

It is at once apparent that the drop in the notifications is almost as marked at the ages below school-age as at school-ages, and is also well marked at ages above school-age. The recrudescence after the holidays is also seen in the three groups of ages, though here the increase is most marked in children of school-age.

I am at a loss to understand, if school influence plays the predominant part suggested, why we do not get a

greater incidence of the disease during the many weeks the schools are in session, and when for the most part the curve is below the mean; and I confess I should be inclined to attach greater weight to the coincidences if year by year we found a fall occurring with regularity in the first holiday week, and being maintained throughout the holidays; but this is by no means the case.

The falls during the holiday periods may be accounted for by the smaller number of children at these times in London, and perhaps more fully by the removal of the supervision which is exercised by a staff of some 10,000 teachers during school periods.

It may be, and frequently is, necessary that the school should at this time be visited by a skilled medical man for the purpose of examining into any condition which may suggest itself, including the examination of the children, and the Board are considering at this moment whether any further effective arrangements can be made in this respect.

From a study of this evidence, it may be necessary to close a department or a class-room, in which case the committee concerned is so advised; or the disinfection of one or more rooms may be desirable, when the assistance of the Local Sanitary Authority is solicited. In any case a copy of the return and all the facts of the case are brought under the notice of the Medical Officer of Health interested, and a conference by telephone or otherwise obtained.

Further, if any children in attendance at school show symptoms of an infectious disease, they are at once to be excluded, and intimation given both to the Medical Officer of Health and to the medical officer of the Board; and for this purpose the teachers are instructed in the various symptoms of the different infectious diseases.

Clinical Records.

TABETIC OPHTHALMOPLÉGIA. (a)

Under the care of Dr. LEONARD GUTHRIE.

This patient, a postman, æt. 65, seven months ago suddenly developed ptosis of the left eyelid with crossed diplopia and external strabismus. For twelve months he suffered from weakness and unsteadiness of gait, giddiness, and tremors of head and right arm. Two years ago he had some kind of fit attended by momentary loss of consciousness, but no similar attack had occurred since. He had had a chancre, followed by non-suppurating bubo and severe sore throat at the age of 24. He had been six months under observation, during which time the symptoms became less marked, but the left eyeball deviated outwards as before, and could not be moved upwards nor inwards beyond the mid-line. Quite recently, the right eyeball also could not be moved inwards beyond the mid-line, nor upwards, but its movements outwards and downwards were unimpaired.

The pupils were moderately contracted and reacted little, if at all, to light. Accommodation could not be tested owing to loss of convergence. The knee-jerks, present six months' ago, had gradually disappeared. His gait had become more ataxic, and Romberg's symptom was now manifest. Sensation was unaffected except that the ulnar nerves behind the inner condyles were abnormally insensitive. He had some difficulty in holding his water. No "lightning pains." Dr. Guthrie considered that the diagnosis of tabes was now obvious, although six months previously the presence of tremors, and the absence of any definite signs of the disease, including that of "lightning pains" had created doubt as to the nature of the case. He drew attention to the frequent occurrence of paralysis of ocular muscles as pre-ataxic symptoms. Such cases of ocular paralysis usually came under the notice of ophthalmic surgeons, and were frequently cured, or the paralysis spontaneously subsided, perhaps years before other signs of tabes appeared.

Transactions of Societies.

CLINICAL SOCIETY OF LONDON
MEETING HELD FRIDAY, JANUARY 12TH, 1900.SIR R. DOUGLAS POWELL, Bt., President, in the Chair.
CLINICAL EVENING.

COMPLETE SUBPERIOSTEAL RESECTION OF OS CALCIS.

MR. J. HUTCHINSON, jun., showed a young man, *æt.* 17, on whom he had performed complete subperiosteal resection of the os calcis for osteo-myelitis with excellent results, in that the patient was able to walk and bear his weight upon the reformed bone. The only drawback was some retraction of the great toe.

MR. HERBERT PAGE remarked that the operation was by no means a novel one, his father having done it as far back as 1840.

MR. HUTCHINSON, in reply, repudiated any claim to originality, observing that though not new the operation was sufficiently rare to make it of interest in view of the result.

PAROXYSMAL HÆMOGLOBINURIA IN A CHILD.

MR. LUNN showed a girl, *æt.* 6, the tenth of twenty-four children, of whom fourteen were living, in whom the peculiarity was noticed when one year of age. From time to time she passed port wine urine containing normal red cells. The proportion of red corpuscles to white in the blood was about half normal. Her sister was suffering from interstitial keratitis, which pointed to syphilis.

MR. LUNN also showed a child, *æt.* 5, with congenital luxation of the right hip, also a man and a woman suffering from double facial diplegia.

MR. W. G. SPENCER recalled a case he had shown of a boy with paroxysmal hæmoglobinuria, who had had several attacks of dry gangrene, the first attack dating from his sleeping out one summer's night. The case, he said, was obscure, but Professor Osler had noted cases of Raynaud's disease with high arterial tension associated with, apparently, congenitally thickened arteries. Many such cases ended early in life by uræmia or apoplexy.

MR. J. JACKSON CLARKE asked what treatment the author had adopted, or proposed to adopt, in the luxation case. He observed that it was one of the slighter degrees of congenital dislocation, therefore, not one urgently calling for treatment. He called attention to the limitation of abduction in these cases, and suggested resort to Lorenzi's bloodless method.

DR. VOELCKER commented on the interest of the evidence of syphilis in the connection with hæmoglobinuria, adding, that in a large proportion of these cases there was a definite history of inherited syphilis. In one case, to which he referred, there was a history of acquired syphilis. On examining the blood, he had noted an undue tendency of the red corpuscles to cohesion, forming snake-like coils and the corpuscles were elongated or lemon-shaped.

DR. SUTHERLAND recalled that paroxysmal albuminuria and hæmoglobinuria had been described as alternating manifestations of the same condition. Another condition often present in these cases was an excess of oxalates, this excess persisting for a considerable time after the hæmoglobinuria had passed off.

MR. LUNN said that he had not adopted any treatment in the luxation case fearing to make matters worse than they were. The hæmoglobinuric patient usually got a rise of temperature with chill and collapse when the attack was imminent, but in the intervals her health was good. They had suspected heightened tension. Oxalates had been found in the urine, but the intermediate urine appeared to be normal.

MALIGNANT DISEASE OF THYROID AFTER TWO OPERATIONS.

MR. CHARTERS SYMONS showed a woman, *æt.* 58, who came in September, 1897, with a growth in the left lobe of the thyroid. The enlargement had been noted nine years before but had remained stationary until 18 months previously. When he saw her there was a large fixed swelling pushing the windpipe over to

the right and causing a good deal of dyspnoea. He removed a large portion of the growth and then performed tracheotomy in November, 1897. In the spring of 1899 the pressure returned and he then extirpated the whole of the left, and the major portion of the central lobe of the gland leaving only a portion too deep behind the sternum for safe removal. The operation was almost bloodless. She had paralysis of the left vocal cord but could speak distinctly. There was no longer any discomfort. He called attention to the comparatively small amount of blood lost, as was usual with purely epithelial growths of the gland, and he insisted on the peculiarity of the growth remaining unilateral, and on the supervention of malignancy on long standing enlargement of the gland.

MR. A. BARKER remarked on the fact that malignant growths of the thyroid often ran a very chronic course, a peculiarity which he thought was characteristic of malignant growths in this situation, and he alluded to a case of his own which had lasted 18 years, 12 of them under his own observation.

MR. SYMONS, in reply, said that in one of his cases the history extended over ten years but in another only twelve months.

EXCISION OF THE NECK OF THE LOWER JAW FOR ANKYLOSIS.

MR. JACKSON CLARKE showed a girl, *æt.* 8, who had had complete fixation of the lower jaw for upwards of three years. He cut down over the right temporo-maxillary joint through an incision planned to avoid the trunk of the facial nerve, the parotid duct, the superficial temporal artery, &c., and removed the neck of the bone. The result of the operation was entirely satisfactory, and after a few days the patient could masticate food and promptly gained in weight. She could now open the mouth more than an inch and close it perfectly. He referred to another case in which he had performed similar operations on both sides for bilateral ankylosis with equally good results.

MR. BARKER observed that it used to be taught that such operations were useless because the condition was sure to recur, probably because the wounds did not heal aseptically. He asked whether some interference with growth affecting the symmetry of the face was not to be apprehended after these operations.

ARTHRECTOMY OF KNEE FOR TUBERCULOUS DISEASE.

MR. F. EVE showed a girl, *æt.* 13, who had come with tuberculosis of the knee. Treated in the usual way no improvement followed, so he performed arthrectomy through an incision over the patella, which was divided, the capsule being opened by lateral incisions, taking care to spare the lateral ligaments. The semilunar cartilages were removed, and one crucial ligament had to be cut through but was afterwards refixed to the bone. The lower end of the internal condyle was ulcerated, and had to be scraped, and the capsule was then carefully sewn up, union running an aseptic course. There was actually very free movement, almost to a right angle.

MR. BARKER expressed the hope that such a case as this might become the rule instead of being the exception.

MR. SYMONS recalled a case of his own in which he had performed a similar operation six years ago, but the patient had recently complained of pain.

MR. HUTCHINSON, junr. said that in two cases of arthrectomy he had got 30 degs. of flexion, but still not as good a result as in this case. He remarked that in cases of extensive disease it might be risky to try to obtain this result instead of contenting themselves with obtaining a perfectly stiff limb.

MR. JACKSON CLARKE said he had never seen such a good result. He himself usually applied Thomas's splint with results, on the whole, encouraging. If one could choose one's cases arthrectomy might, however, be the operation to be preferred.

MR. EVE, in reply, said he hoped to show the patient again at some future date. He admitted that the case was from the first distinctly of a subacute nature. Where there was much caseation and ulceration he would not attempt it.

RESECTION OF RADIUS FOR SARCOMA.

Mr. EVI also showed a young woman who, after an injury developed a tumour presenting the symptoms of myeloid sarcoma of the radius. In March, 1897, he removed the lower thirds of the radius and ulna. The tumour was encapsuled in bone. He shortened all the flexor tendons except the flexor carpi radialis. He defended the removal of the lower portion of the ulna, on the ground that otherwise the hand would ultimately have assumed a position at right angles to the limb. When, however, the ulna was the bone involved it might not be necessary to remove the radius. There was very good movement of the hand, and the patient could even write.

A CASE OF HEREDITARY ATAXIA.

Dr. VOELCKER showed a small boy, *æt.* 12, under observation for four years. After an attack of German measles (?) at 5 he developed trembling which was diagnosed as chorea. He was brought to the hospital in 1896 on account of unsteadiness of gait, which increased when the eyes were closed, and the knee-jerk was absent. Recently sight had begun to fail, and Mr. Gunn had reported that there was well-marked retino-choroiditis with atrophy of the nerves and sclerosis of the retina, changes which were regarded as syphilitic. There was no disturbance of sensation or involvement of the sphincters. No muscular wasting, but some amount of lateral curvature of the spine. He had been treated with iodides, but without benefit.

Mr. HUTCHINSON, junr., asked whether the ocular changes *per se* could be taken to justify the diagnosis of syphilis.

Dr. VOELCKER, in reply, read Mr. Gunn's report, but admitted that he had failed to discover any other evidence of congenital syphilis.

Mr. SHAW showed a man, *æt.* 40, who, after an injury to the wrist ten years ago, followed by formation of abscesses, had developed a curious condition of the hand, which was swollen, livid, very tender, and painful, the condition tending to spread up the arm. The hand was cold and movement was greatly impaired. He remarked that it might be a case of lymphatic oedema or erythromelalgia.

EXCISION OF TONGUE FOR MALIGNANT GROWTH.

Mr. BARKER showed an elderly man, whose tongue he had removed five years ago for epithelioma, without recurrence.

Mr. BARKER also showed a man (with skiagram) who sustained a slight blow to the knee on the ice. On examination no special injury could be detected, but he took the precaution to cause a skiagram to be made, whereupon a very distinct fracture of the patella was evident. Even with that knowledge, however, it was difficult to detect.

HARVEIAN SOCIETY OF LONDON.

MEETING HELD THURSDAY, JANUARY 4TH, 1900.

H. E. JULES, F.R.C.S., President, in the Chair.

ORBITAL EXOSTOSIS.

THE PRESIDENT showed a young woman, first seen in 1892, with a small hard nodular mass at the inner angle of the left orbit fixed to the nasal process, blocking the nasal duct, causing a mucocele, and the lower canaliculus was slit up. He discussed the desirability of removing the tumour.

Mr. ROUGHTON advised the removal of the tumour, and thought the best instrument for the purpose would be the surgical engine.

COCCYGEAL TERATOMA.

Mr. FRANCIS JAFFREY showed a large tumour removed from the coccygeal region of a female infant, *æt.* 6 months, partly fluid and partly solid, which on

closer examination proved to be a case of teratoma. The tumour had increased in size after admission. It had been tapped twice, and some fluid like turbid beer removed; this fluid was evidently not cerebro-spinal in origin, nor did it correspond to amniotic fluid. The cyst in question had probably arisen in the usual manner, viz., as representative of an attempt at another embryo.

Mr. RAYMOND JOHNSON thought the tumour was probably one of the more common multilocular cystic tumours occurring in this region. The tumour probably extended up between the sacrum and rectum, and its removal would involve a more extensive operation than the child could at present stand.

DEFORMITY OF ARM.

Mr. HUBERT PHILLIPS showed a youth, aged 17 years, with considerable shortening of the humerus, what appeared to be the upper extremity of that bone projecting on the inner side of the arm when the biceps were called into action. Curiously enough, nothing abnormal was noticed until the patient fractured his right arm about nine years ago. He considered that surgical interference was not only not called for, but would be absolutely injurious, as the arm was a most useful one in every way.

Mr. ROUGHTON and Mr. JACKSON CLARKE regarded the deformity as the result of a fracture of the upper part of the shaft of the humerus which had united at an acute angle.

Mr. JACKSON CLARKE showed a male patient, *æt.* 37, who sustained a severe compound and comminuted fracture of both bones of the left leg in July last. A fragment of the tibia measuring over 3 ins. had to be removed because it was quite separated from its periosteal and other connections, and it was contaminated by dirt from the roadway being ground into it. The two remaining segments of the tibia were approximated and fixed by silver wire, and recovery was uninterrupted. The patient has now a useful limb in which 3 ins. of shortening is compensated for by a raised boot.

SYPHILITIC DISEASE OF BRAIN.

Dr. JAMES TAYLOR showed two cases illustrating the result of anti-syphilitic treatment in syphilitic disease of the brain. The first case was that of a woman whom he had brought before the Society eighteen months previously and who at that time had right-sided hemiplegia following typical Jacksonian epilepsy. The patient had been treated with iodide of potassium and mercury with complete success. The second case was that of a man who was at first believed to be suffering from ordinary epilepsy. The attacks were, however, followed by left-sided hemiplegia, headache, and optic neuritis. Iodide of potassium was given internally, combined with inunction of mercurial ointment. After a considerable time the fits ceased, and the other symptoms improved, but recurred with cessation of the treatment. The latter was resumed, and now the patient only presented a very slight degree of weakness, especially in the left leg, and occasional faint attacks.

Dr. LEONARD GUTHRIE read notes of a case of "Tabetic Ophthalmoplegia," which will be found under "Clinical Records."

The PRESIDENT and Dr. JAMES TAYLOR discussed the case, and agreed upon the frequency of ocular paralysis in the early stages of tabes. Dr. Taylor had seen a number of such cases at the London Ophthalmic Hospital, and had usually found the knee-jerks still present. The paralysis was usually transitory, but it might be permanent, and was then probably due to nuclear changes.

CONGENITAL DISLOCATION OF HIP.

Mr. ROUGHTON showed a man of 20, who exhibited the characteristic appearances of a bilateral dislocation.

Mr. JACKSON CLARKE remarked upon the favourable results which had been obtained in the treatment of this deformity in early life by Lorenz's bloodless method.

Dr. SUTHERLAND and Dr. TAYLOR also spoke, and Mr. ROUGHTON replied.

BRADFORD MEDICO-CHIRURGICAL SOCIETY.
MEETING HELD DECEMBER 19TH, 1899.

The President, Mr. W. HORROCKS, F.R.C.S., in the Chair.

Dr. KERR showed a case of extensive wound of the eyeball extending through the ciliary region. There had been sympathetic irritation of the opposite eye, but this had subsided, leaving good vision. The injured eye had not been removed, but the prolapsed iris was snipped off and the lids washed out immediately after the accident.

Dr. EURICH showed a series of microscopic sections illustrating the commoner diseases of the breast.

Dr. HIME showed a specimen of the bacillus of bubonic plague.

Dr. ALTHORP showed a patient who had been treated by laparotomy when suffering from tuberculous peritonitis. The patient was in good health.

CONTAGION IN MODERN TIMES.

Dr. SMALL read a paper on contagion in modern times. (The paper was a continuation of one previously communicated to the Society, on the Ancient Ideas of Contagion.)

In the Middle Ages many diseases were considered contagious, but some of them were also traced to other causes. Epidemics, for instance to poisoned air, which idea did not tend to promote ventilation; to putrefaction from internal causes, what we now sometimes call auto-infection; to the influence of stars, planets, eclipses, earthquakes and volcanoes; to famine or too great plenty and to supernatural beings. Sometimes there was a strange mixture of natural and supernatural causes. There was little attempt to define the influence of the various agencies. Diseases were equally indefinite, but Rhazes, in his description of small-pox and measles had introduced the specific element which ultimately altered the whole aspect of the matter. Leprosy was a prominent example of contagious disease, but it diminished in importance after the epidemic of syphilis at the end of the fifteenth century. No doubt the two had often been confounded. The great plague of 1384, since known as the Black Death, drew much attention to the subject of contagion. Many fevers that we should now call typhus, and consider contagious, were then looked upon as caused by chills or other causes. Small-pox was by no means thought to be infectious at all times and places, and even plague was doubtful to some authorities. What appears to us an extreme reluctance to admit contagion was sometimes shown, some preferring to attribute a large mortality to fear alone. In this matter there have always been sceptics, their minds continually asking "how?" and "why?" not being satisfied with mere contact as a cause in the absence of some far-reaching theory to explain the *modus operandi* of contagion.

Mr. BASIL HALL read a paper on "Tuberculous Disease of the Great Trochanter," and gave reports of three cases."

France.

[FROM OUR OWN CORRESPONDENT.]

PARIS, January 14th, 1900.

ANGINA PECTORIS.

At the Medical Society a member spoke on the treatment of angina pectoris, which he considered should attract the attention of every medical practitioner more particularly as he can render considerable service in this affection. The treatment was twofold, that of the attack and that of the interval between the attacks.

Above all the patient should be enjoined absolute rest. The windows of the room should be opened to procure as much pure air as possible. Mustard to the legs, neck, and præcordial region, so frequently employed by persons in attendance on the patient, should be discarded; it did no good and only wasted time. Injection

of morphia on the other hand was a good means of treatment; open, however, to the objection that if it were necessary to use them often, there was danger of intoxication or of accustoming the patient to the drug, producing finally morphia-mania. Chloral was too slow in its action to be employed at the moment of the attack, and in any case it had a toxic effect on weak hearts. The same might be said of chloroform and ether by inhalation.

Iodide of ethyl and iodide of amyl, on the contrary, gave good results, but nitrite of amyl, in doses of from 18 to 20 drops on a handkerchief, should be preferred. Certain patients derive great benefit from nitro-glycerine, that is to say, those whose faces are congested, but with those who become pale during the attack and cadaverous looking it does not succeed so well. Hydrobromate of quinine, given at the outset of the attack, prolongs the action of the nitro-glycerine. Other remedies have been recommended for angina pectoris such as pyridine, cigarettes of stramonium, lobelia, &c, but they are only of value when attacks of asthma coincide with the angina, or in cases of pseudo-angina pectoris provoked by acute aortitis, neuritis of the cardiac plexus, pericarditis, or Bright's disease.

Once the attack has terminated the medical attendant should apply himself to prevent a return, or to diminish its frequency and intensity. To reach that result it was necessary to treat the malady of which the angina was a symptom. From what is known up to the present on the subject true angina pectoris is the result of sclerosis of the coronary arteries produced by chronic arteritis.

Iodide of potassium is the best agent in such cases; it should be given for months, if not years, at small doses (5 to 15 grains daily). The greatest perseverance is necessary, but to avoid iodism the treatment may be suspended ten days a month. In following that treatment the patient was almost sure to obtain very good results, and some had completely recovered. Instead of iodide of potassium, iodide of sodium, or strontium, or lithium might be given, but they are inferior to iodide of potassium.

During fifteen days every month the nitro-glycerine may be given to advantage; it dilates the vessels, and favours the circulation through the coronary arteries and their branches, facilitating thus the nutrition of the heart. Igni-puncture over the heart often renders good service, but if the patient objected to it, tincture of iodine might be used instead. As to abdominal massage recommended some time ago, it had not given any result in the speaker's practice.

The régime of the patients should be that of patient suffering from a grave heart affection:—Moderation at table, suppression of alcohol and tobacco, avoid moral emotions, muscular efforts, fatigue, dwell in a mild climate.

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, January 13th, 1900.

At the Medical Society Hr. Gottschalk showed a NECROTIC PIECE OF PUERPERAL UTERINE WALL, with microscopic preparations. The portion was cast off along with foul-smelling discharge 18 days after delivery. On November 13th the speaker was called to

a primipara who had been three days in labour. The liquor amnii had escaped four days before. The pains were strong, the head not yet engaged. The patient was small, with a universally contracted pelvis, the conjugate about 9 ctm. The head at the inlet pressed on the swollen lip of the womb. The abdomen was very pendulous, the uterus firmly contracted. All the conditions for rupture of the uterus were therefore present. Forceps were tried under chloroform without effect; turning was then performed, a living child being extracted. The uterus contracted well, and the placenta was expressed. The pulse continued high, and two days afterwards strong rigors took place, with quick rise of temperature to 40 degs. C. On seeing the patient four days afterwards he found high fever. Pulse 130, abdomen considerably distended, painful. The discharge was sweet, since delivery, no sleep. The uterus was washed out with a litre and a half of a 1 per cent lysol solution, and afterwards 1½ litres of a 60 per cent. solution of alcohol. The condition went on getting worse to the sixth day. The pulse could not then be felt. A camphor injection did not improve matters, and as the condition was the same the next day a supra-clavicular saline infusion of one litre was made, followed by a striking improvement, and the patient slept. The pulse, however, still remained so quick that digitalis and strophanthus had to be given. The discharge became foetid on the fifteenth day, and on the eighteenth a portion of mucous membrane came away which was saturated with cocci, in the lymph tracts, and veins, along with numerous thrombi. The patient recovered. With regard to washing out with alcohol, absolute alcohol acted as a caustic, but a 60 per cent. solution did not. This only acted by extracting water, and contracted and irritated vessels. In the future he would not place much reliance on it, but, on the other hand, the saline solution he could recommend as a life-saving measure. This view had been since confirmed in a later observation. He looked upon the case as one of partial gangrene of the uterus.

Hr. Kirchner followed with a paper on

LEPER HOUSES—PAST AND PRESENT,

in which he gave a history of these institutions from the first, founded in 564 by Gregory of Tours. In the twelfth and thirteenth centuries there were 2,000 of these houses in France alone; every large village had one, generally named after some saint. The leper houses were the predecessors of hospitals. After leprosy had been extinguished for centuries it was observed in some parts of Russia, and especially in 1832, 1842, and 1850, and houses were established for the reception of cases. In Norway fresh advances had been made in the treatment of the disease by Armaner Hansen, and model leper houses were established in several towns. The disease was comparatively rife in Russia; 1,600 cases were officially notified, but probably 5,000 would be nearer the number. The speaker then went on to describe the relation of the disease to Germany and the measures taken to arrest its spread, and said that with the aid of leper houses and prophylactic measures the chronic diseases would be extinguished.

Hr. Virchow said that leprosy had never spread epidemically, but only partially, and in certain localities, but that there it had decimated the population. He was convinced that leprosy had never extended like syphilis did after

its first introduction to Europe; even after the Crusades its extension had never been so great. It had never been so prevalent and so infectious as the laity had represented. This erroneous idea of the laity had often been taken up by medical men. Even now diagnosis was not easy if the case was not of the tuberculous form. He held to the traditional view of the identity of "Zaraath" with leprosy. It was certain that many cases of other skin diseases had at times been classed under leprosy, as had been the case formerly with regard to syphilis. The Holy Ghost hospitals were not to be placed in the same category with the St. George's hospitals; only the latter served for the reception of lepers, and were located *extra muros* (as in Berlin the St. Jürgenhaus was situated in front of the Königsthor whilst the Holy Ghost hospital was *intra muros*, and was used for all diseases). Kirchner's view of the connection between the present city hospitals and the old lazarettos was not quite correct. The upward movement of modern hospitals dated from the time when they passed into the hands of the community, and were withdrawn from the religious bodies. There would never be any epidemic of leprosy—any fear of this kind might be absolutely excluded—neither could there be any compulsory separation of such patients. He, the speaker, saw and examined every year a considerable number of leprosy cases coming from foreign countries which were not known to the police, and which remained here without restraint and had never given rise to contagion. The measure taken in Memel would, therefore, be enough to prevent further extension.

Hr. Blaschko said that the mode of infection was very enigmatical. He had heard of cases where a couple had been married forty years without the husband infecting his healthy wife, and of others where fourteen days had sufficed to infect. It was necessary to keep a watch over the Russian borders particularly in certain districts, and to favour voluntary visiting of hospitals so that the inmates should not be cut off from the whole world, and to support on the part of the State those dependent on patients who had entered hospitals.

Hr. Korte said that at the Cape of Good Hope, the spread of the disease had almost reached the dimensions of an epidemic. At present the numbers reached 6,000 to 8,000. In a limited territory, where in 1870 lepra was unknown, an inquiry made in 1886, shortly before his departure from the district, showed no less than 900 cases. These facts showed the importance of an energetic watchfulness with regard to the disease in tropical and sub-tropical regions.

Hr. Kirchner, in reply, said there were insurmountable financial difficulties in the way of government support of the dependents of the inmates of leprosy houses. As much might be expected for the dependents of tuberculous cases in hospital. On account of the peculiar manner of the spread of the disease, prophylactic measures should not be given up. Urbanowitz had ascertained that two elderly ladies in poor circumstances had been infected by a seamstress, quite a number of families by a beggar, others by a maid servant, &c. From Koch's investigations it was known that in some cases of apparently nerve leprosy the nodules in the nasal mucous membrane gave off a mass of bacilli; whether these were capable of setting up infection was not known.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, January 13th, 1900.

RENAL DISPLACEMENT.

At the Gesellschaft der Aertze, Hochenegg showed a malformed kidney which he had removed as a tumour from the left side of a female patient. The history of the tumour pointed to a congenital origin, and, after careful examination, it was concluded to be an "Intra-ligamentous Myoma." As the swelling had been the cause of much worry and bodily discomfort, it was decided to remove the tumour *per vaginam*, as by this means it would be extra-peritoneal. For twenty years, in addition to the psychical depression which had led her several times to attempt suicide, she suffered from intractable constipation.

Hochenegg operated by the sacral method, but on reaching the tumour he was surprised at the amount of fat and large vessels leading into it. Closer inspection revealed a triangular small kidney, with the hilus in front, its vessels proceeding from the iliaca communis.

After the operation she soon recovered, the constipation disappeared, as well as the psychical disturbance, while the urinary secretion became normal, both in quality and quantity.

Kundrat recorded his experience of these congenital abnormalities. He had met with them both bilateral and unilateral. When unilateral the left side is a most frequent seat, and their position varies, though the pelvic cavity is a frequent site. He has met with them in the peritoneal cavity both unilateral and bilateral as well as crossed, that is, the left kidney in the right side of the body, while the right occupied the left, which may be termed crossed dystopia. These displacements are usually associated with other malformations such as deficiency of the organ itself, or of the ovaries and tubes. Atresia is also a frequent complication.

The clinical importance of dystopia may be arranged in three classes:—(a) Does this displacement produce nephritis, hydro-pyonephrosis, calculous formation, or other diseases? According to Strube these diseases are met with more frequently under these circumstances than in the normal position, although he admits that anuria is not uncommon from compression of the ureters. (b) The obstruction to labour and fæcal discharge as in Hochenegg's case. Cases of this kind are recorded in which the kidney has been expelled from the vagina during labour. (c) The severe nervous symptoms which are extreme and protracted.

The diagnosis is usually confirmed by operation, and is more difficult in the male, being confounded with sarcoma of a cryptic testicle, periproctal abscess, and tuberculous glands; in the female with myoma, ovarian and other tumours.

A PORTABLE OPHTHALMOSCOPIC DARK ROOM.

At the Medical Club Bundi showed a very ingenious apparatus which formed a dark room for examining the eye with the ophthalmoscope in the open sunshine.

The arrangement is formed of an extensible frame, on which is stretched black cloth, and which envelops the heads of both operator and patient. A small electric light is attached by means of a hoop to the front of the

patient's head, whereby the operator can examine the eye either directly or indirectly.

The whole apparatus can be folded up like an umbrella.

ATAXIA TREATMENT.

At the "Doctoren Collegium" Bum introduced the subject of spinal ataxia and its treatment by compensatory movements. He quoted from Frenkel in 1890, who affirmed that the ataxic movements can be restored to the normal condition by repeated exercise. Leyden extended this doctrine and attempted to prove that the sight could be made to supplement the musculo-articular sensibility. Another theory was advanced that the sensory ataxia, by which co-ordinated movements were performed, depended on the integrity of the sensory sphere. From this it was inferred that such exercise treatment did not improve the sensibility, as the regulation of the central apparatus was the primary demand.

Bum was of opinion that the innervation of the antagonistic force was at fault, and was in favour of treating it by resisting movements. In conclusion he attempted to classify suitable cases for such treatment, and said it was not the degree of inco-ordination, but the character of the case that should determine the prognosis.

In rapidly developed cases or during the exacerbation period of moderate cases the exercise treatment is injurious. Old well-nourished, inactive cases improve rapidly by this treatment, but if amaurosis, malnutrition or psychical disturbance were present, such treatment should be abandoned. In the discussion that followed Roth recommended every ataxic patient to be examined ophthalmoscopically, and if atrophy of the optic nerve, diplopia, &c., were present, exercise should be prohibited. Winkler said that many ataxic patients were advised to practise this exercise-treatment at home without any dosage being prescribed, whereby more harm was done than good. He could hardly accept the exclusion of active and passive gymnastics, as many of our old brethren have applied the electric treatment with marked success which might yet be proved to be valuable in many of these cases. Haudek was of opinion that the prognosis depended very much on the muscular system and general nutrition. He was inclined to the treatment with baths of tepid water or, what he thought better, carbonic acid baths.

Scheimpflug reminded the members present that it was possible even in amaurotic ataxics to practise the exercise treatment where the tactile impressions could be educated. Bum replied that blind ataxics could not be so treated because the feeling was so much impaired.

The Operating Theatres.

MIDDLESEX HOSPITAL.

GASTRO-JEJUNOSTOMY.—Mr. JOHN MURRAY operated on a girl, æt. 19, for pyloric obstruction. She had been admitted six weeks before operation under the care of Dr. Pasteur, suffering from vomiting of ten months duration, coming on immediately after taking solid food and accompanied by pain in the epigastrium. The patient was pale, anæmic, and markedly emaciated. At the tip of the ninth costal cartilage on the right side was felt a raised, hard, nodular tumour. It measured two inches transversely, but its upper limit could not be defined..

It extended two inches below the costal margin. It was tender and moved slightly with respiration. The stomach resonance was obtained over a large area, and the organ was evidently dilated; there was no enlargement of the liver or of the spleen. During the period the girl was under observation in the hospital she vomited frequently, sometimes as much as five pints at a time; the vomit was very offensive, and contained large numbers of sarcinae; the diagnosis made was pyloric obstruction, the cause of which was doubtful. An operation was undertaken for the purpose of exploration and also for relieving the condition. The stomach having been washed out, the patient was placed on the operating table and lying on a hot water bed. The abdomen was opened in the middle line by an incision from the ensiform cartilage to half an inch above the umbilicus; this revealed a large and apparently malignant mass involving the pylorus and the pyloric end of the stomach, and extending to a considerable extent along the lesser curvature. The tumour was fixed posteriorly in the situation of the pylorus; several hard lumps were felt in the lesser omentum which were probably enlarged glands. Removal of the mass being impossible, it was decided to perform gastro-jejunostomy. The stomach was drawn out of the wound and a spot chosen on the anterior wall just above the greater curvature and as far over to the left as possible; the jejunum was next found and brought round to the left border of the transverse meso-colon, and a part selected about ten inches from its commencement, this was brought into apposition with the spot chosen on the anterior wall of the stomach; sponges were completely packed around each viscus so as to avoid soiling the peritoneal cavity, and the surfaces of the stomach and jejunum united posteriorly by a row of Halsted's sutures, these were tied and the ends cut short; the posterior row of sutures being also carried round, so as to approximate the surfaces laterally; then a similar row of sutures was introduced anteriorly. An incision an inch long was next made between the two rows of sutures, both into the stomach and into the jejunum. A little gas escaped from the stomach on its being incised, but no fluid or solid matter. The edges of the incision of the stomach were united by a few points of interrupted suture to the corresponding point of the cut surfaces of the jejunum the anterior row of sutures were then tied. The peritoneum was wiped over with sponges and the external wound united by three layers of sutures after the parts operated on had been dropped back into the peritoneal cavity. Mr. Murray remarked that the operation was undertaken first of all for the purposes of exploration, it being doubtful whether the cause of the pyloric tumour was fibrous or malignant, the age of the patient rather pointing against the latter. For this reason the incision was made in the middle line. The appearance of the growth on opening the abdomen was distinctly malignant, and it involved not only the pylorus, but a considerable area of the anterior wall of the stomach, being fixed posteriorly, and several nodules which were presumably enlarged glands, were felt in the lesser omentum. The extent, size, and fixity of the tumour rendered pylorotomy impossible, and the only alternative was to unite a portion of small intestine to the stomach in order to afford a means of outlet for the contents of the latter. The anterior wall of the stomach was chosen for anastomosis, as being more convenient

than the posterior. The commencement of the jejunum at its junction with the duodenum was easily found and a spot about ten inches from this was selected for union with the stomach. Halsted's method of suture was chosen as being easy of application and on account of its bringing a larger area of the surfaces of stomach and jejunum into apposition. After the posterior row of sutures had been introduced two interrupted sutures at each end were inserted as a means of additional security. After the viscera had been opened the cut surfaces of the mucous membrane were united by a few points of interrupted suture, partly to control the hæmorrhage and partly to bring the openings of the stomach and jejunum into accurate apposition. Mr. Murray thought the method by direct suture was preferable to anastomosis either by Murphy's button or by Senn's plates.

It is satisfactory to state that four weeks after operation the patient is going on well; she has had no vomiting, and was able to take solid food a fortnight after the operation. The convalescence has been delayed, however, by thrombosis of the common femoral vein.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, JANUARY 17, 1900.

ON THE SANATORIUM TREATMENT OF PULMONARY TUBERCULOSIS.

It is rather a curious thing that the open air treatment of consumption should be sprung upon us now as a new and trustworthy means of combating the disease in spite of the fact that most authorities, from the time of Sydenham downwards, have alluded to it in no uncertain tones as the best, and indeed as the only valid, way of controlling its ravages. But the fact remains that this method until quite recently had never been recognised and adopted as a definite method of treatment. Up to the present indeed it cannot truthfully be said that there has been any definite method of treat-

ment for a disease which levies a heavy toll, year by year, on the population of all European countries. We have had enough and to spare of the so-called specific treatments, not one of which has resisted the experience of a few months or years, but we are now brought face to face with a plan which, in early cases and under favourable circumstances, is unquestionably capable of affording a variable measure of relief. It remains for us to establish what are these circumstances, and the discussion which recently occupied three entire meetings of the Royal Medical and Chirurgical Society, if it has not materially added to our knowledge, has at any rate cleared the air. We thoroughly endorse the preliminary protest uttered by Sir Richard Douglas Powell against the use of such a catch phrase as "Sanatorium treatment" as though the existence of the sanatorium was the indispensable basis of the treatment. We much prefer the term open-air or hygienic method, which term has the merit of placing in relief the conditions which militate in favour of recovery. It simply amounts to this, that a predisposition to pulmonary, and probably to other forms of tuberculosis, is created by living in houses from which fresh air and light are largely excluded. Observation and common sense both point to this as the primary cause of the disease, the greater or less abundance of the infective agent coming after. Under normal conditions of health we can defy the tubercle and most other bacilli, but if vitality is sapped by particular modes of existence the pathogenic organism obtains a footing from which no medicinal treatment yet devised can dislodge it. A good deal of the discussion turned on the architectural requirements of the model sanatorium, but, for the time being, this is perhaps of less importance than the principles which underlie the treatment. It is encouraging to find that there is no material difference of opinion as to the essential value of the method although the details of its application give rise to much divergence of views. One point of considerable importance was made clear, viz., that open-air treatment is one thing, and sanatorium treatment another. No one ever complains of a draught on a mountain top, whereas in the average sanatorium draughts are the order of the day. Fresh air at almost any temperature produces excellent results, but draughts, though they do not necessarily give rise to the familiar cold, are productive of a vast amount of discomfort, and must often cause mischief. The principle may be laid down that, to be effective, the open-air treatment must be maintained throughout the whole twenty-four hours. The vitalising effect of many hours passed daily in the open is minimised by a night passed in a closed bedroom, so that if the treatment is to be effectual it must be continuous. Another fact elicited by the discussion was the importance of collateral measures, such as suitable diet and regulated exercise, as adjuncts to the open-air treatment. Although an abundant dietary is an important auxiliary of fresh air, we must not be led astray

by mere increase of weight, which is by no means synonymous with improvement. It is necessary to bear this in mind, because otherwise we might be tempted to regulate the dietary with the view of obtaining a gain in weight without regard to the physiological requirements of the individual patient. In this connection a point was mentioned incidentally which may prove to have important bearings in the future, viz., the influence of a largely nitrogenous dietary in controlling the disease. Tuberculosis, it is obvious, is rarer among classes of society where meat enters largely into the daily food and carnivorous animals are, as a class, much less prone to the disease than their herbivorous fellows. The data at present available on this point, however, are insufficient to enable us to draw any practical conclusion from the suggestion, and in any event no one scheme of dietary is likely to prove beneficial to all patients without regard to previous habits and personal idiosyncrasy. In discussing the "cure" of such a disease as tuberculosis, it is obviously necessary to define what is meant by the term. Dr. Allbutt went so far as to assert that he would not reckon as cured any patient who had not resumed his ante-tuberculous conditions of existence for a whole year without showing any recurrence of the disease. Measured by such a test the proportion of cures would be small indeed, but Dr. Kingston Fowler knocked the bottom out of this argument by remarking that return to previously-existing conditions of existence is precisely what the cured patient must never aim at. On the contrary, his one aim in existence must be to approximate his future life to the conditions under which he has recovered health. As it is, after all, the conditions of environment that determine the vulnerability of the individual, the individual once again exposed to their debilitating influence will become, if indeed he has not remained, vulnerable. The most interesting point, both for the profession and for the public, is the share in the success of the treatment to be accorded to the sanatorium factor. For the poorer class of sufferers, of course, the sanatorium affords the only means of carrying out the method. It means removal to healthier surroundings, better nourishment, absence of worry, and a higher standard of comfort all round. These, combined with rest, will suffice to turn the scale in, possibly, the majority of cases. But is this sequestration indispensable in the case of persons whose usual surroundings are not unsanitary or comfortless and whose nourishment is not inadequate, in whom, indeed, life in the open air and properly regulated exercise are the principal factors to consider? Surely these patients might carry out the treatment in their homes. They have only to observe the precepts on which all authorities are agreed, open windows, regular habits, and the avoidance of excesses, it being understood of course that the sufferer will conscientiously carry out the injunctions laid down for his guidance. It is here that the personality of the medical direc-

tor of the sanatorium comes into play. He it is who can reinforce the dormant will-power of the patient, and who will induce him to conform to the details of the treatment. The subject as it has been presented in this prolonged discussion is far too wide for us to attempt to deal with in the limits of a single article, and we reserve sundry other points for future reference.

THE SALVATION ARMY SHELTERS.

AFTER several years of litigation the question of the efficient sanitary supervision of the Salvation Army Shelters has been placed on a satisfactory, common-sense, legal basis. The history of the whole matter forms an instructive chapter in the annals of public health administration and development in the United Kingdom. Some years ago the Council prosecuted the owners of a shelter for not being registered as common lodging-house keepers, and in the upshot a decision was given in favour of the Salvationists in the case *Booth v. Ferrett*. The case, however, was reopened by the energetic medical officer of St. George's, Southwark, who traced some cases of small-pox to a large shelter in his district. Finding, therefore, that it was impossible to secure efficient disinfection and sanitary supervision of a large and shifting population of the poorest class he was after a good deal of fruitless negotiation compelled to take stronger measures. Entry was obtained one night under a magistrate's warrant and the gross overcrowding then found became the subject of a magisterial conviction. Practically from this litigation it followed that the Medical Officer of Health and the police had no power of visiting one of these shelters at night, the only time when a domiciliary visit would be of any avail. Moreover, it allowed a professedly philanthropic undertaking to qualify its charity to the extent of charging various sums ranging from a penny to sixpence or more for accommodation, to say nothing of other charges for food, washing, and so on. In this way Mr. Booth's organisation was able to compete against the common lodging-house keepers under conditions that gave him an overwhelming advantage. The whole matter resolved itself into a simple commercial transaction in which stringent and costly regulations were enforced on the one side for the safety of the public, simply to be evaded and laughed at by the other to the great danger of the outside community. Happily, however, the resources of civilisation were by no means exhausted and undeterred by former failures, the London County Council again set to work and instituted a fresh batch of prosecutions, only to be ruled against by the magistrate, who while he expressed general agreement with the contention of the Council nevertheless felt himself bound by the decision of the case of *Booth v. Ferrett* to say that the shelters did not fall within the definition of common lodging houses. The next step was the hearing by the Queen's Bench Division of a special case stated by the chief Metropolitan magistrate.

The Council charged "General" Booth with keeping a certain common lodging-house without being a registered lodging-house keeper under the special Acts of 1851 and 1853. After a long and patient hearing the Lord Chief Justice of England delivered judgment in which he allowed the appeal, so that henceforth the semi-charitable, semi-commercial night shelters will come under efficient sanitary supervision. The learned judge disapproved of the principles that had influenced the decision in *Booth v. Ferrett*. He laid down the important principle that even where a house or building is carried on for charitable objects that fact should not place it outside sanitary supervision. The question was not with what object or motive the house was conducted, but whether the house was so carried on as a lodging-house as to be within the provisions of the Act, as it was clearly within the mischief aimed at by the Act. If large numbers of the most wretched class were lodged in common rooms in sanitary conditions were, in the absence of inspection, supervision, and control, likely to arise, and it was the object of the law to secure efficient control. The common-sense of that view is evident, namely, that so far as the public health is concerned, it does not matter one jot whether the motive actuating the keeper of the shelter be philanthropic or mercenary. The second ground of decision in *Booth v. Ferrett* from which Lord Russell dissented was more technical. The judge in that oft-quoted trial decided that a refuge did not fall within the statute, because a common lodging-house was open to all comers in the sense that the keeper could not refuse admission to any applicant. As a matter of fact the common lodging-house keeper exercised a power of rejection, and there was no legal compulsion that bound him to admit, say, drunken and disorderly persons or those of known evil reputation. The question as to the exact position of charitable night shelters in relation to the local sanitary authorities is now fixed upon a satisfactory basis. To have permitted the state of affairs disclosed by the Vestry of St. George's to have continued would have been seriously to checkmate the progress of public health administration in the United Kingdom. With a full recognition of the good work done by the Salvation Army, we must confess that the position of passive and active resistance assumed by "General" Booth in this matter surpasses our comprehension. He has used the resources of the "Army" to resist the right of supervision by the sanitary authorities of large number of vagrants and outcasts whom he has congregated nightly under conditions proved to have been contrary to the first principles of wholesomeness. He has asserted that the shelters are not conducted on a commercial basis, but has failed to substantiate that assertion by a production of accounts. Indeed, he appears to belong to a class of worthy people who cannot bring their emotional impulses into line with the demands of the community that no individual should interfere with their physical welfare. Were it not for the commercial aspect of the shelters we would say that their emotional aspect would

command the widest respect, even where judgment could not follow. On the whole we concur with the final words of Lord Russell, who said:—"We trust that those who are charged with the enforcement of the law will do all they can consistently with their duty and consistently with effecting the objects of the law to avoid anything like harshness or unreasonableness in its enforcement."

THE DUBLIN HOLOCAUST.

WE are pleased to note that the views which we expressed last week respecting the excessive mortality in the City of Dublin, and its causes, have been considered worthy of notice by everyone of our daily contemporaries in Dublin, and, especially that they have generally confirmed our views by their mature experience. The *Freeman's Journal* alone has acrimoniously differed from us, but its criticism is limited to two points. First that our mortality statistics were not exactly correct. Second that, if they were, the fault for omission to reform the life conditions of the poor does not lie with the Corporation, but with the law which forbids it to acquire building sites compulsorily. On both of these points the *Freeman's Journal* is easy of refutation. The mortality statistics of Dublin are issued weekly, and the figures for this week will not be exactly the same as those of the last. Our figures were substantially accurate according to the most recent returns when the article was written, a few days before publication, but not mathematically correct at the latter date. But what boots such squabbling about decimals? while it is notorious that, for the recollection of the oldest inhabitant of the city, its death-rate taken, not on a week's returns, but on a year's or twenty years' has been, chronically, largely in excess of that of any similarly situated town in the Kingdom, and but little less than that of the most malarious towns of the east. Will the *Freeman's Journal* deny this or will it rack its brains for a passable apology for the fact? Since we wrote the Dublin death-rate, as officially stated, has risen from the 46.0 per 1,000 of the population to 51.3, and the latest returns of the Registrar-General for a whole month set it down as 41.7, the slums of Glasgow being represented by 28.6, and the average of twenty town districts in Ireland as about 25 per 1,000. The second excuse offered by our contemporary for toleration of the present horrible conditions of the habitations of the poor, that the Corporation cannot get sites for new houses except by clearing areas at enormous expense, is equally devoid of substantial foundation. We know that the Corporation has made the citizens pay for the purchase of the occupation rights of a large number of favoured individuals in order to make room for outrageously costly dwellings for artisans who are perfectly well able to pay, for accommodation elsewhere but we repeat that for the housing of the very poor, which we have in view, no such extravagance is necessary. There are several sites for moderate sized dwellings which are derelict and can be had for almost nothing, and which would as they now are be a disgrace to any

Corporation, but a shilling will not be expended on them for the benefit of the very poor. We repeat and insist that there can be no hope of a mitigation of the terrible insalubrity of the City but by improving the life-conditions of the poor, and we see no very great eventual difficulty in doing so, if only the Corporation would take as much interest in the problem as it does in hauling into the City boundary communities which vehemently resist their extinction by annexation.

The urgency of this question may be judged from the fact that the Lord Lieutenant has evinced his earnest interest in the welfare of the poor of the City in which he resides by convening a conference of the Local Government Board, the City Health Officer and His Excellency himself to discuss the situation and the remedy, and we are certain that a wise conclusion will be thus arrived at, but we must say at once, that unless that conclusion embodies the ultimate extinction of the tenement house system, and the substitution of a proper model lodging-house system, it will prove as totally unavailing as several panaceas have done before. For the realisation of such a great aspiration, the co-operation of the Corporation is indispensable. It must find the money, and must indicate its outlay in such a way as not to inflict another intolerable blister upon the overburdened ratepayers, and we earnestly trust that the citizens will not permit any renewal of the ineffectual tinkering of the present system which has been going on for the past twenty years. At least £50,000 must be found as a first instalment, and it must be spent not upon law costs or upon the buying up of the property of any one's bosom friend nor in architects' and builders' jobs, but in providing good, substantial dwellings for very poor people. After that is accomplished it will be necessary to move the poor population into these dwellings without violating their convenience or feelings unnecessarily, and, afterwards, nothing will remain but to extend the system, control it properly, and await a result which must be a long way off.

Notes on Current Topics.

The Contracted Pupil of Deep Slumber.

IT is a point of some clinical importance to bear in mind that during deep sleep the pupils are contracted strongly and that they dilate at once on waking under healthy conditions. An American writer, Dr. Robby, of Boston, has called attention to this fact as giving rise to a possible fallacy in diagnosis. Two children were brought to him with a history of a fall. They were unconscious and in both the pupils were of pinhole size. The knee reflexes of both were active, and in applying that test to one of them the child awoke and the pupils instantly dilated. The second child was not roused by the tapping of the knee, but later upon being awakened the pupils at once expanded to the normal size. Since then Dr. Robby has examined twenty-two healthy sleeping children, and in all of them he found the pupils were of pin-hole size and dilated instantly

upon waking. The practical value of the observation lies in the fact that children often sleep soundly while undergoing an examination that would at once rouse an adult. Indeed, a tired baby presents a picture that resembles in many ways that of narcotic poisoning or cerebral injury. Should the pupils not dilate instantly and equally upon waking the observer will be furnished with suggestive evidence of traumatic or drug injury. The physiological side of the matter has long been set forth in the text-books, but it is doubtful whether its clinical bearing is recognised among medical men to the extent it deserves. The point might readily become a crucial one in medico-legal cases, especially when brought forward to controvert evidence of head injury diagnosed after a brief examination. If Dr. Robby had not discovered the real state of affairs in the two cases above mentioned, he might quite confidently have stated later that they showed signs of cerebral injury.

A New Hospital Scheme.

THE suggestion by Dr. Telfer, of Montreal, that there should be in every house a room which can readily be converted into a hospital ward is without doubt excellent in the abstract. But certain difficulties appear to be insurmountable with regard to its practical realisation. In the first place want of space would, in the majority of households, prevent any such scheme being carried out. The author's idea, however, is not to take up an important part of a house and reserve it for use only in time of sickness, but that one room should be so adapted for hospital use that in half-an-hour, when required, it could be changed into a more or less complete hospital. He suggests, therefore, that the ceiling, walls, and floor should be finished in such a manner as to be readily washed; the furniture so constructed as to be capable of being sterilised, and special arrangements made for a separate lavatory and water closet for the sick persons. That is to say, in order to give full effect to the idea it would be necessary to have special plans made for such a room before beginning to build a house, and then all difficulties would be removed. We do not doubt for a moment that a hospital room as suggested would prove of great use under favourable circumstances. For example as an isolation ward for children suffering from one of the symtotic diseases, or for an operation case, or for obstetrical purposes. In each of these instances the advantages of the arrangement could not fail to become self-evident.

"The Medical Parliamentary League."

ANOTHER effort is about to be made to induce members of the Profession to become organised reformers, and thus an association has been launched with the above title, whose objects will be to do some more tinkering with the proposed legislation for midwives and other things. In truth a curious phase is now prevalent in regard to medical politics. At no time so much as the present has the subject of medical reform degenerated so unmistakably into a

trade. Family quarrels have taken place among a certain class of would-be reformers, and a split in the camp has ensued. Thus the unedifying spectacle is before us of two reforming bodies, each with its own little weekly trumpet bidding for popular favour among the medical public. As a matter of fact, however, this craze of reform is being much overdone. The profession, or at least a large proportion of it, is becoming nauseated with the persistent chatter and garrulous outpourings of those who have constituted themselves the champions of reform. Take for example the vexed question of legislation for midwives. We find that, of course, in the interests of the profession, it has been dealt with (1) by the British Medical Association, (2) by the Corporate Medical Reform Association, (3) by the Incorporated Medical Practitioners' Association, and (4) it is the first matter to which the "Medical Parliamentary League" will devote its energy. That is to say, four bodies, ostensibly working with reform objects in view, have expended, or are now expending, their efforts to make legislation for midwives acceptable to the profession. The only conclusion which can be drawn from this undesirable state of affairs is that a good many practitioners would be much better employed if they were to devote more time to their legitimate calling than wasting it in attempting to pose as medico-politicians.

Infirmiry Nurses and Dancing.

THE nurses of the Fulham Infirmiry, so it has been currently reported, have recently been on the verge of a strike, because their matron endeavoured, to prevent the annual ball. The guardians, however came to their rescue, and decided that there should be no departure from the annual festivity that custom had sanctioned so far as to warrant fixed expectation by the nursing staff. It is said that many of the guardians attended the ball in person, and that is partly the reason why they have adopted their present attitude. We fail to see the necessity for any explanation other than the tendency of latter days to enlarge the boundaries of rational enjoyment so as to include larger and larger sections of the community. Infirmiry nurses belong to a hardworked sisterhood, especially when their lot is cast within the four walls of a Poor-law Infirmiry, where the prevailing atmosphere is anything but rose-coloured and exhilarating. Why they should be deprived of the solace of a yearly dance is past the average comprehension. In the bad old days of Bumbledom the bare proposal of such a carnival would have sent a thrill of horror through the length and breadth of the Poor-law service. Even nowadays the old spirit crops up now and then, so far as nurses are concerned, generally in the person of some sour middle-aged spinster to whom the duties of nurses' superintendent have been entrusted. It is a pleasure, on the other hand, to come in contact with a large staff of nurses under a matron of well-educated and broad-minded modern type, who does not object to dancing and who does not think that the mingling of the

sexes in social intercourse is necessarily demoralising. It is not an uncommon experience that the stricter the moral lacing of an institution the more lax is the nursing administration proper.

The Surgeoncy to the Queen's County Infirmary.

THE long disputed question of the surgeoncy of the Queen's County Infirmary was decided, so far as the new governors have power to settle it, on the 10th inst., by the election to the office, supposed to be vacant, of Dr. Arthur Joseph MacAuley Blayney, formerly resident surgeon and resident physician at the Mater Misericordiae Hospital, Dublin, and lecturer in Biology in the Catholic University. Dr. Blayney qualified in 1893 as M.D. and M.C. of the Royal University, and as a student had a distinguished career. A brief narrative of the events of this election will be interesting. Up to the spring of 1898 the surgeoncy was occupied by Dr. William Jacob, who had the co-operation of his father, Dr. David Jacob, and their joint administration of the institution for a long series of years was not and could not be seriously challenged by their bitterest enemies. When, however, the dominant control of the infirmary passed into the hands of the new County Councils elected under the Irish Local Government Act, the dominant party in that Council thought they saw their way to oust these gentlemen and to substitute one of their own colour, to wit, Dr. Higgins, coroner for the district and dispensary doctor at Stradbally, about eight miles from the infirmary, who possessed the pre-eminent qualification for a hospital surgeoncy that he is brother-in-law to Mr. Tim Healy, M.P. To effect this change a very undiplomatic resolution was passed by the dominant majority, but only by one vote, purporting to dismiss Dr. William Jacob on the ground that he holds the dispensary and the Asylum in Maryboro and, therefore could not effectively discharge the Infirmary duty, an objection which applied obviously, with tenfold force to Dr. Higgins, a candidate who held office ten miles away, and might be called to conduct inquests in all parts at which he might be required to attend as judge for days together. For this and for other reasons to which we need not refer, a large section of the electors split off from supporting Dr. Higgins, and decided to run a second candidate on the same party lines. The original Governors of the Infirmary who support Dr. Jacob refused to take part in any election as they contend that his dismissal was totally illegal, and that he is still, *de facto*, Surgeon to the hospital, and this question of law is about to be submitted to the courts. Thus, when the vote was taken on the Wednesday last, Dr. Blayney was chosen by a majority of one vote, the original Governors abstaining, and Dr. Higgins was completely hoist with his own petard, and the new surgeon will occupy the position unless or until he is unseated on the point of law. The election is of general interest because it is the first occasion on which an Irish county infirmary surgeon has been attempted to be dismissed by the newly dominant party. All such officers who held

office before March 31st, 1898, are safe of their seats, but all appointed since then and all to be elected in future will live at the mercy of the dominant party, who may, and will, wipe them out of existence the moment they blench before the popular political programme.

Tabloids v. Prescriptions.

THE *Pharmaceutical Journal*, in its last issue, charges us with having "impudently asserted that compressed tablets afford facilities for the administration, in minute doses, of the very active alkaloids which the practitioner prudently hesitates to order in a prescription." We did say so, and we adhere to the statement, and call the general practitioner as our witness. We never had the remotest intention to belittle the skill of the pharmacist, but we should like to see the general practitioner who would venture to hand to a patient from the country a prescription for half a dozen pills containing each of them, say a thirtieth of a grain of strychnia, or phosphorus, or strophanthin, or cocaine, or atropine. Our contention is, simply, that such drugs as these cannot be compounded even by the most capable and conscientious chemist without the risk that the entire dose will be concentrated in one or two pills, and we are convinced that the Editor of the *Pharmaceutical Journal* knows this perfectly well. The tabloid makers can grind a drachm or an ounce of strychnia into a multitude of tabloids, but the individual dispenser cannot be certain of effecting the same subdivision with safety for half-a-dozen pills, no matter how hard he tries. Our observations were chiefly directed to persuade the pharmacists that it will be ineffectual and foolish to set up a trades-union opposition to the public buying of tabloids and other conveniently concentrated medicaments. It would be, in our opinion, wiser advice to them if the *Pharmaceutical Journal* would recommend them to adapt themselves to the inevitable change in the public taste, and while not too soon abandoning the dying prescription system, to cultivate the trade in such medicaments.

"Strumous Ophthalmia."

It is not a little remarkable that some ophthalmic surgeons should still persist, in teaching that such a disease exists as "strumous" ophthalmia. A few years ago a "strumous" ulcer of the skin always meant what is now called a "tuberculous" ulcer, and therefore now-a-days to speak of "strumous" ophthalmia can only mean "tuberculous" ophthalmia. But the advance of knowledge has taught that the tubercle bacillus is not answerable for any of the conditions which formerly were described as "strumous" ophthalmia; consequently the retention of this term under the circumstances is quite opposed to the scientific teaching of the day, and is moreover misleading. Again, the word "strumous" having now become obsolete from the introduction of the term "tuberculous," it is safe to assume that within a decade or two more, it will pass altogether out of medical nomenclature. Certainly, neither the modern physician nor the

modern surgeon can have any occasion for reverting to the word "strumous" in the course of his teaching, and hence the modern ophthalmic student is probably at a loss to understand why an ophthalmic surgeon should refer to an ophthalmia as strumous when it has nothing to do with the tubercle bacillus.

Notification of Measles.

SOME of our readers may recollect that when, many years ago, it was proposed to enact the compulsory notification of disease, we strongly advocated the system of voluntary notification, because it was free from the danger that disease would be deliberately concealed by both the patient's friends and by the practitioner in charge, with the object of escaping the domestic annoyance and dislocation of business which necessarily follows upon compulsory sanitation. We urged the adoption of the voluntary system, at least as an experiment, because it had been tested in Greenock for some years previously, and had given complete satisfaction, but the compulsory system now in operation was preferred, and, as we anticipated, has resulted in the concealment of a certain proportion of the infective disease in the country. We recur now to the subject, having observed that the Corporation of Wigan has, at the instance of its medical officer, approved of a further extension of the voluntary system, in the case of measles, for three further years, while in many towns the compulsory system works with much friction, and in very many other towns where it is nominally in force it is a dead letter, no serious attempt being made to bring it into operation.

The Study of Botany.

HEALTHY intellectual life is hardly compatible with too exclusive concentration of the mind upon any one pursuit, especially if that pursuit be at the same time the professional avocation of the individual. Every intellectually active man requires a hobby of some kind, which serves the double purpose of enlarging the scope of his ideas and of providing him with a never-failing source of distraction and amusement. For persons whose life runs its more or less even tenour in the country what more interesting pursuit can there be than botany? Foremost among the natural sciences it helps to develop the mind, and opens it to the beauties that surround one on every hand. It is greatly to be regretted that this charming science does not attract more favourable attention than is the case, and the fault is doubtless to some extent to be found in the neglect shown in the elementary schools towards a subject which, even if cursorily taught, is replete with interest and instruction. From a medical point of view, much as the medical practitioner would profit by a fairly complete knowledge of this branch of observation, the curriculum is already too heavily laden for it to be possible to include it among the studies imposed upon the medical student. But the subject might well be accorded a prominent place among the subjects of preliminary education; indeed, in view of its bearing

on *materia medica* it might even be made compulsory. We commend this suggestion, which emanates from a correspondent who signs himself "An Admirer of White of Selborne," to the Education Committee of the Medical Council, as the preliminary examinations are just now under consideration.

A Case of "Larva Migrans."

UNDER this somewhat indefinite heading a case was recently reported at a meeting of the Toronto Medical Society, and accompanied by a photograph of the patient, showing a sinuous, tortuous line coursing over the pectoral region on the right side. The history was that the line first appeared on the back, and was about one-eighth of an inch in diameter. It increased in length from one half of an inch to three inches and a half every day, then in order to put a stop to these migratory proceedings a "fly" blister—obviously a most appropriate remedy under the circumstances—was applied about one inch beyond the advancing trench works, and the parasite, having failed to recognise the necessity of performing a flank movement, delivered a frontal attack upon the fly-blistered area, as a result of which it fell a victim to a blunder in tactics, and the patient was cured. We are informed that the larva of some insect burrows in the skin in these cases, thus producing the lesion. Precisely, but it would have been more to the point if some steps had been taken in this case to ascertain the nature of the larva and thus have thrown some light upon the subject. As it stands, the case is quite incomplete, and whether the lesion was or was not caused by the bot fly, no one can tell. All that the author is able to assert is that it was cured by the "fly" blister, an assertion, however, which has no value respecting the nature of the "fly" which rendered its application necessary.

The Significance of Chilblains.

THE rounded purple, dusky little swellings that come upon hands and toes in winter are familiar to most inhabitants of cold climates under the name of chilblains. Less often they attack the ears, nose, or cheeks, but wherever situated they give rise to a most troublesome burning and itching sensation. The general rule is that they appear in parts of the body remote from the heart, and are most frequent in the young and old. They are prone to occur in persons who suffer habitually from cold hands and feet, that is to say, in those who have a weak or, what Hutchinson calls, a "chilblain circulation." Anæmia is another predisposing condition. The essential nature of this interesting complaint is that it is a damage to the skin, resulting from cold, in short, a mild frostbite. In some cases it approaches the latter state more nearly by the formation of blisters, when the chilblain is popularly described as being "broken." There is no complaint in which more infallible remedies are prescribed by "hobnail" tradition. A favourite plan is to whip the affected parts with a bunch of stinging nettles, a homely but most efficient form of counter-irritation. A Swedish method is

for the sufferer to run several times barefooted round a field covered with snow. Perhaps one of the best ways of prevention in persons of sluggish temperament is to take active exercise and to wear warm woollen gloves and socks. The latter hint may be of use to those who are sending out comforts to our soldiers at the Cape, where the severe weather is sure to call forth a plentiful crop of chilblains, and add, not a little, to the discomfort of the brave men who are fighting our battles in the open.

The Canary Islands for Convalescent Soldiers.

A CORRESPONDENT, writing to the *Times*, makes the very practical suggestion that advantage should be taken of the situation and climate of the Canary Islands for our wounded soldiers. Certainly at this time of the year the return to England of the wounded and sick must be attended by much discomfort and even danger, while the admirable climate of these lovely islands provides an ideal *milieu* for their recovery.

A Museum of Cataracts.

COLONEL GEOFFREY C. HALL (I.M.S.) seems to have established a record. He states in a small publication that he has operated for cataract in 8,000 cases, and that he has all the extracted "lenses carefully packed in bottles to confute the doubter." Thus he must have quite a museum of cataracts. But we feel in some doubt as to what he means by the "doubter." To whom does it refer? It is not to be supposed that there could be anyone bold enough to doubt Colonel Hall's word that he has done 8,000 extractions. Such a feat, it is well understood, could be quite possible in India, where thousands of natives suffer from cataract. Indeed, this disease prevails to such a large extent, that the operation for cataract is one of the most common in the Indian Peninsula, and many surgeons have done their thousands of cases with, and perhaps, without, benefit to the natives. It is, however, quite a novelty, we believe to keep, as Colonel Hall has done the extracted lenses "to confute the doubter."

A Phenomenal Death Rate.

A DEATH-RATE in the large towns of England varying between 37 and 40 per 1,000 is calculated to divert attention to some extent from the losses which we are sustaining by less normal means in South Africa. Although the leaps and bounds which have characterised the returns for the last few weeks are certainly rather startling, it will be seen that the effect of the epidemic of influenza which is, probably correctly credited with the enhanced death-rate, is mainly exerted on the elderly, indeed an immense majority of the deaths have occurred among persons over sixty years of age. It follows that influenza merely strikes down within a limited space of time a number of persons who would have died in a few weeks or months by efflux of vitality; in other words, when the statistics for the whole year are made up, the average mortal-

ity will not be found to have been appreciably affected by the present high mortality. This reflection is calculated to encourage the timorous, because it goes to show that it is not the result of the disease of itself, which, indeed, is but the precipitating cause of a disaster which was in most cases imminent.

Medical Men and the Auxiliary Service.

A FEW days since we published an appeal signed by several influential members of the profession, urging medical practitioners to show their sense of patriotism by offering their services to one or other of the auxiliary services. The present is certainly an opportune moment for urging this matter on members of the profession. Connection with a volunteer or yeomanry corps offers many advantages, both social and professional. Not only is the medical officer discharging a patriotic duty, but he brings himself, thereby, into contact with a large and influential section of society, and the community of arms constitutes a bond which is not to be despised even from the selfish point of view of professional advancement. The drills afford relaxation, both physical and mental, and the annual manoeuvres provide an agreeable change from the ordinary routine of practice. The expense connected with these posts is not necessarily very heavy though we are fain to admit that the cost of the initial outlay for uniform and equipment appears somewhat inflated, a point which our military authorities might well consider, because it cannot be doubted that the obligation of expending between £60 and £70 on uniform, &c., frightens away many a man who would otherwise be delighted to enrol himself.

The Surgeoncy of the City of Dublin Hospital.

We understand that on Monday, the 8th inst., the Medical Board of the Hospital selected the three applicants for the surgeoncy, who it, is incumbent on them to recommend to the general Board of Governors, who will select one from the three. The names chosen by the Medical Board were those of Mr. Henry Croly, M.B. and M.Ch., and B.A.O. of the University of Dublin, formerly resident surgeon in the Hospital and in St. Mark's Eye and Ear Hospital; Mr. Henry Moore, Licentiate of the Colleges of Physicians and Surgeons, surgeon to the Mercer's Hospital, and formerly resident surgeon in the City of Dublin Hospital; and Mr. Richard Lane Joynt, M.D. Univ. Dub. and F.R.C.S.I., assistant-physician to the Meath Hospital. We understand that the general Board of Governors will meet on Friday next to make the selection from these three applicants.

The "Reuben Harvey" Memorial Prize.

THE approaching award of this prize, which is given triennially by the Colleges of Physicians of Ireland for the best essay on some subject evidencing original research in animal physiology and pathology will be made on July 2nd, 1900. The prize consists of £25, and the competition is open to all students of medical

schools recognised by the Colleges, and also to all licentiates and graduates of not more than three years' standing. The competing essays must be lodged with either of the Registrars of the Colleges before June 1st.

THE epidemic of influenza is so severe in Birmingham that many thousands are under medical treatment, and twenty-two deaths were attributed to it last week.

PERSONAL.

MR. ALFRED D. FRIPP, assistant surgeon to Guy's Hospital, is on his way to the front.

DR. T. B. COLEMAN, F.R.C.P.I., has been appointed to the staff of Lord Iveagh's Irish Hospital for South Africa.

SURGEON-CAPTAIN P. H. WHISTON, Royal Army Medical Service, has been appointed to the medical staff in the Home District.

DR. EDGAR A. BROWNE was elected president of the Liverpool Medical Institution for the ensuing year at the annual meeting held on Friday last.

DR. BACCELLI, the Minister of Public Health in Italy, has consented to inaugurate the new School of Tropical Medicine in this country in May next.

DR. JOHN SHOOLBRAID has been awarded a pension of £50 per annum by the Aldershot District Council on his retirement as Medical Officer of Health of Aldershot.

DRS. MCCORMACK and SCOTT SKIRVING, two of the leading surgeons of Sydney, are accompanying the New South Wales Contingent to the front where they will have the honorary rank of major.

DR. W. CHEYNE WILSON has been appointed by the Admiralty to give instruction in the use of the Röntgen Rays to naval medical officers who will, as occasion permits, be sent to the Naval Hospital, Plymouth, for that purpose.

THE additional sum of £10,000, which the Earl of Leicester has promised to the Norfolk and Norwich Hospital, brings up the total benefactions of the noble earl to this hospital to £50,000. The new building to which the latest contribution is promised is to be called the Leicester Home for Nurses.

MR. DOWNES, the president of the Pharmaceutical Society of Ireland, has found it necessary to resign his office, and his retirement has been accepted by his colleagues with unanimous expressions of regret and sympathy. Mr. Downes met with a serious street accident many months ago, and, unfortunately, has not regained health as he recovered from it. His occupation of the presidential chair has been marked by energy and discretion such as few presidents evince, and it fell to him to deal with the knotty question of company pharmacy, which he did wisely, though the result of his work has yet to come.

A Few days ago Mr. Richard Gravely, M.R.C.S., was presented with a jubilee testimonial to mark the completion of his 50 years' residence in the village of Newick, Surrey. The testimonial consisted of a solid silver antique inkstand, a pair of silver candlesticks, a case containing a silver pen, pencil, and paperknife, a cheque, and an illuminated address. On the inkstand is engraved: "Presented to Richard Gravely, Esq., resident in Newick 50 years—1849-1899—by his many friends," and the address itself states: "That the presentation is in token of their appreciation of the constant interest shown by him in the welfare of the inhabitants of Newick and the neighbourhood during his 50 years' residence among them."

Correspondence.

We do not hold ourselves responsible for the opinions of our correspondents.

SICK AND WOUNDED OFFICERS' SURGICAL AND MEDICAL AID FUND.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I shall be glad to be afforded the opportunity of making an appeal in your columns on behalf of those sick and wounded officers of all services whose means are inadequate to secure that efficient medical and surgical treatment which will often be needed to restore to them, after their return home, the health they have sacrificed in the service of their country. Among the great number of officers who have unhappily been wounded or are suffering from disease contracted on service there will certainly be many who have small private means, and who are not in a position to command the skilled assistance they will urgently need. In many cases continuous treatment for long periods will be necessary. Though to offer assistance in such cases will be a matter of considerable delicacy, nevertheless I feel sure that it will be generally felt that an attempt should be made to do so.

The under-mentioned gentlemen have consented to act upon a general committee, and to assist the objects of the scheme in every way within their power. A fund has been opened to which I earnestly trust many of your readers will readily contribute. The provision of accommodation for convalescent patients is a part of our scheme, and I have already received several offers from private persons which I have no doubt that the committee will be glad to entertain.

Subscriptions may be sent to Messrs. Coutts, Strand, London; the Duke of Abercorn, Hampden House, Green Street, W.; or to the Honourable Arthur Brodrick, 18, Eaton Square, S.W. (hon. secretary and treasurer to the fund, to whom inquiries may be addressed). Cheques should be crossed "Sick and Wounded Officers' Surgical and Medical Aid Fund."

I am, Sir, yours truly,

ABERCORN.

Hampden House, 61, Green Street, London, W.,
January 11th, 1900.

COMMITTEE.

The Duke of Abercorn, K.G.
The Duke of Portland.
The Marquess of Londonderry, K.G.
Earl Grey.
Lord Farquhar.
W. S. Church, M.D., President of the Royal College of Physicians of London.
H. G. Howse, M.S., Vice-President of the Royal College of Surgeons of England.
John Tweedy, F.R.C.S., Vice-President of the Royal College of Surgeons of England.
Sir T. Grainger Stewart, M.D., Professor of Physic, University of Edinburgh.
Sir W. T. Gairdner, K.C.B., M.D., Professor of Medicine, University of Glasgow.
John Chiene, F.R.C.S., Professor of Surgery, University of Edinburgh.
W. Macewen, M.D., LL.D., F.R.S., Regius Professor of Surgery, University of Glasgow.

J. W. Moore, M.D., President of the Royal College of Physicians of Ireland.
 C. B. Ball, M.Ch., Regius Professor of Surgery, University of Dublin.
 J. Roberts Thomson, M.D., President of Council, British Medical Association.
 Sir Henry Norbury, K.C.B., Director-General, R.N. Medical Service.
 Surgeon-General J. Jameson, C.B., Director-General, Army Medical Service.
 Sir W. H. Broadbent, Bart., M.D., London.
 Sir W. Mitchell Banks, F.R.C.S., Liverpool.
 Sir Francis Cruise, M.D., Dublin.
 Sir Dyce Duckworth, M.D., London.
 Sir William Gowers, M.D., F.R.S., London.
 Sir Francis Jeune, K.C.B.
 Sir F. Laking, K.C.V.O., M.C., London.
 Sir W. Miller, M.B., London.
 Sir R. Douglas Powell, Bart., M.D., London.
 Sir W. O. Priestley, M.D., London.
 Sir Thomas Smith, Bart., F.R.C.S., London.
 Sir Thornley Stoker, F.R.C.S.I., Dublin.
 Theodore Dyke Acland, M.D., London.
 H. W. Allingham, F.R.C.S., London.
 T. Annandale, F.R.C.S., Edinburgh.
 C. A. Ballance, F.R.C.S., London.
 Thomas Barlow, M.D., London.
 G. T. Beaton, M.D., C.M., Glasgow.
 Ernest Beckett, Esq., M.P.
 E. H. Bennett, F.R.C.S.I., Dublin.
 W. H. Bennett, F.R.C.S., London.
 Walter Bernard, M.D., London.
 Hon. Arthur Brodrick.
 J. Walter Browne, M.D., Belfast.
 B. W. Burnet, M.D., London.
 Lieutenant-Colonel W. J. Charlton, R.A.M.C., Netley.
 W. B. Cheadle, M.D., London.
 W. W. Cheyne, F.R.C.S., London.
 H. H. Clutton, F.R.C.S., London.
 Alfred Cooper, F.R.C.S., London.

ARTHUR BRODRICK.

Honorary Secretary and Treasurer.

BACON RASH—A QUERY?

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—During the recent epidemic of measles whilst attending a sick bed I noticed that the patient's mother was covered over face, breast and arms with a rash which very closely simulated measles. On inquiry I found she was subject to the rash every time she ate bacon, either boiled or fried, and had been so from childhood. The diet caused her no other inconvenience than keeping her within doors for twenty-four hours. About one hour after eating the food the rash appeared, first showing on the face and then spreading to the chest and arms. It finally faded away in the order in which it came. The woman's temperature was normal, her appetite good, and she attended to her household duties as usual. She enjoys a dinner of bacon and would eat it more frequently if it were not for the rash which certainly follows its use. The quality of the bacon used is the best Irish, so the rash cannot be ascribed to diseased food.

Bacon is so largely used as a food that I thought it probable that some other practitioner might have come

across an identical idiosyncrasy, but a careful search of Dr. Neale's "Digest," last edition, and some other reference books failed to find a reference to an identical case, hence my letter.

I am, Sir, yours truly.

GEORGE FOY.

"A SAD AND URGENT CASE."

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I beg to enclose you a list of donations up to date in response to the appeal of Dr. Macnaughton Jones, which I have received subsequent to the previous one, which you kindly published. Will you be so good as to favour this, likewise, with an insertion in your journal?

I am, Sir, yours truly,

WILLIAM H. BOURKE, M.D., Hon. Treas.

Obituary.

DR. ROBERT COLLUM.

THE death of Dr. Robert Collum, of Furbiton, at the advanced age of 86, creates a solution of continuity with a very interesting chapter of history. He qualified as for back as 1836, and subsequently entered the service of the Honourable East India Company, where he was for long attached to Sir Charles Napier's staff, indeed he was alone in medical charge of the 55th on the "Zenobia," a transport on which cholera broke out, killing 64 soldiers in eight days. This, however, was but an incident in a long career, which bristled with responsibilities and adventures. On his return in 1857 he took up the cause of the members of the Royal College of Surgeons of England, becoming president of their society.

THE past ten days has produced a deplorable mortality amongst well-known members of the profession in Ireland.

DR. HUMPHRY MINCHIN died in London at a very advanced age, having withdrawn some years since from all professional practice. He took his first qualification at the Irish College of Surgeons in 1838, and his university degree at Trinity College in 1840. He served in early life as Medical Officer of the Castlereagh Dispensary, and afterwards, for a long period, as Medical Officer of the North Dublin Union and Physician to the City Prisons. He was also Professor of Botany in the School of the Irish College of Surgeons until that chair was abolished. Dr. Minchin was deservedly esteemed in a social sense. He acted as treasurer of the Irish Medical

Association for many years, and was familiar with Dublin social circles as an accomplished musician—a very skilled composer as well as a performer.

Dr. SAMUEL ROBERT MASON died last week most unexpectedly at his residence in Merrion Square, Dublin, at the early age of 47. He was the eldest son of Dr. Thomas Peter Mason, well-known as the founder, with Mr. Ledwich, of the Ledwich School. He took his first qualification from the Irish College of Surgeons in 1873, and followed it up with the M.D. of the University of Dublin and the Fellowship of his College. He devoted himself to the practice of obstetrics, at which he was very successful, becoming afterwards Professor of Midwifery in the College and Master of the Coombe Lying-in Hospital. He accepted the latter appointment when the hospital was in most adverse circumstances, and was very successful in restoring it to its former régime. We understand that he was taken ill in his bed at midnight, and died before medical aid could be obtained.

Dr. STEPHEN O'SULLIVAN, of Cork, joined the profession as M.D. of the Queen's University, and L.R.C.S., Edin., in 1862, and speedily rose in rank in his native city. He became house surgeon of the North Infirmary, and afterwards full surgeon of that, and several other similar institutions. He then became Professor of Surgery in the Queen's College, and served as Secretary of the Surgical section of the British Medical Association, when it met in Cork in 1879. Having enjoyed the confidence of the public for many years, he died at the age of 64.

Dr. HUMPHRY JOHN BROOMFIELD died also very unexpectedly last week. He commenced professional life as a Licentiate of the Dublin Colleges in 1881, and associated himself with teaching in the Carmichael College where he was Lecturer on Anatomy. At the same time he was Assistant Physician in the City of Dublin Hospital and when the Carmichael College was merged in the school of the College of Surgeons, he became college anatomist in the latter institution. A few years since he accepted the surgeoncy of the Carlow County Infirmary, and thereafter practised in that vicinity. It is understood that he had recently suffered from some internal disease, but did not undergo operation for it.

Dr. ROBERT LINDSAY HUNTER died at his residence in Larne, near Belfast. He qualified in 1868 as M.D. and M.Ch. of the Queen's University, after which he practised in England for a little. During the Franco-Prussian war he was engaged as a surgeon at the front, and, escaping from Metz during that memorable siege, he fled to America, from which country he returned to his native place. For upwards of twenty-eight years he practised in Larne, and relinquished his duties about a year ago in consequence of failing health. Besides his private practice, he held the important appointments of Admiralty surgeon, medical emigration inspector, and medical attendant to the constabulary, coastguard, the naval reserve, and lighthouse staff in the vicinity of Larne.

Literature.

KEEGAN'S RHINOPLASTIC OPERATIONS. (a)

COL. KEEGAN's name has for some years been honourably associated with the plastic surgery of the nose, and the profession will be glad of this opportunity of studying his methods of procedure in detail, and of observing the results thereby obtainable. This can now be conveniently and well done, for in the book before us the type is unusually clear, the printing does not show through the pages, and the reproductions of the photographs are highly demonstrative and artistic, and the "turn out" highly creditable to the publishers.

Col. Keegan remarks that his rhinoplastic operations were performed at Indore, in Central India, where he was

residency-surgeon for 15 years, where "cutting off the nose is frequently resorted to, not only among organised belligerents, but as a means of avenging personal grievances."

All of his operations were on healthy persons whose noses had been cut off; he had not to operate in the wake of an attack of syphilis or lupus, which, of course, was greatly in his favour.

According to a letter in the "Gentleman's Magazine," of October, 1794, the Indian operation, the design of which has been adopted by Col. Keegan, has been employed "from time immemorial," but Keegan has materially improved the original method, and he is magnanimous enough to say that even his work has been improved upon by his *confère*, Capt. Henry Smith, M.D.

The book is very pleasantly written, and is entirely free of bombast. Every surgeon who henceforth lays himself out to operate upon truncated noses will be sure to turn to Col. Keegan's book, which may truly be regarded as the nasal architect's *vade mecum*.

ARCHIVES OF NEUROLOGY. (a)

THIS large volume, the result of investigations in the pathological laboratory, of the London County asylums, is an earnest of much good work done and much to do. It contains a large number of papers, many of them contributed by Dr. Mott and Dr. Barratt. In his first paper on the relation of syphilis to organic brain disease and insanity, Dr. Mott treats of the difficulties in the way of historical investigation. It is to be hoped that asylum clinical records are not so scanty as the following statement would suggest:—"I have seen the most obvious syphilitic residua overlooked in the notes of cases in the asylums. . . . even such coarse objective symptoms as hemiplegia and facial paralysis have occasionally not been recorded in the notes." The second paper on brain syphilis in hospital and asylum practice, also by Dr. Mott, is a very important one, containing as it does notes of 60 cases and 23 post-mortem examinations. The date of incidence of syphilitic nervous diseases is touched on fully and the views of authorities are quoted. Dr. Ferrier's statement at Edinburgh, 1898, is quoted and evidently endorsed by the author, thus, "his (Ferrier's) experience led him to associate tabes and general paralysis with syphilis to such an extent that he assumed that a man suffering with either of these diseases had been affected." The evidence of syphilis as antecedent in all such cases has not been proved. Mott has demonstrated a larger proportion than was previously known or suspected. There is still a residual unknown quantity, and where syphilis has been demonstrated it has to be demonstrated further that it is the essential factor. Several papers deal with different phases of the study of general paralysis—e.g., the condition of the blood, the amount of water and phosphorus contained in the brain and spinal cord, juvenile general paralysis, &c. A paper of some interest to asylum men is contributed on the "Etiology of Asylum Dysentery," by Mr. H. E. Durham, and a rare specimen of telangiectasis is described by Mr. C. F. Beadles. The volume contains numerous good illustrations, and the papers all through are worthy of the archives.

WILSON'S VICE AND INSANITY. (b)

Dr. WILSON's book is a further evolution of his work on Drunkenness. He here treats of alcoholism from the moral, physiological, pathological, and clinical point of view. We should add also that he has made a careful psychological attempt to explain the reduction of function in alcoholism. His physiological explanation of the effect of alcohol on the neuron, and the consequent effect on mental control is very ingenious to say the least of it. His argument is that nerve force—whatever it may be—circulates in the nervous mechanism constantly, just as much as does the circulation, and unless there is this con-

(a) "Rhinoplastic Operations." By D. F. Keegan, M.D., F.R.C.S., Indian Medical Service, retired. London: Baillière, Tindall, and Cox. Pp. 72. 1900.

(a) "Archives of Neurology." Edited by F. W. Mott, M.D., F.R.C.S. London: P. S. King and Son. 1899.

(b) "Vice and Insanity." By George R. Wilson, M.D. Edinburgh: William F. Clay. 1899.

stant, mild state of stimulation metabolism becomes a dynamical impossibility. This function of nerve motion he calls "tonic," and the effect of alcohol, he holds, is to produce a tonic depression. There is perhaps not anything very new in this, for we have heard of functional activity calling for fresh blood supply; but it is interesting as being expressed in terms of modern physiology, and apparently letting in more light. In his general conclusions on the effects of alcohol we cannot help feeling that the author is sometimes too drastic, and that he has never been able so fully to investigate what we may call the physiological field of the temperate drinker as compared with the pathological of the chronic soaker and the dipsomaniac. A number of interesting clinical cases are given.

Literary Notes and Gossip.

THE "Pocket Case Book for Nurses" (Scientific Press), has been compiled with the object of inducing those in charge of the sick to cultivate the habit of accurate and precise observation. It contains forms for a large number of records, each embodying details of identity and bodily functions, systematically arranged and tabulated. The idea is good, and the plan seems likely to attain the object in view.

THE Watford magistrates a few days since, ordered the destruction of a large number of books seized on the premises of the "University Press Co., Ltd.," on the ground of obscenity. Among them we learn is Féré's "Expression of Emotions" and Havelock Ellis's work on Sexual Pathology. Mr. Féré will be disagreeably surprised at the notoriety thus given to his work.

"The burden of an honour
Unto which he was not born."

THE little "Manual for the Church Lads' Brigade Medical Corps" (2nd edition), is an extremely succinct and handy little volume for the guidance of those who are organising a "first aid" course. After laying down the main lines of the organisation and scheduling the equipments, we have sketched out for us the subjects for instruction, theoretical and practical, with precise directions for the diagnosis and summary treatment of injuries. Then comes ambulance drill with rules for service. Though quite a "pocket" edition, the cost being only sixpence, it is a marvel of concision and comprehensiveness, and it constitutes a trustworthy guide to a very useful course of instruction and training.

AMONG our American brethren medical men are coming well forward as authors of non-professional works. Dr. Weir Mitchell's "Autobiography of a Quack" has just concluded in the "Century Magazine"; Dr. Wm. M. Polk's "Life of Leonidas Polk, Bishop and General," has been a great success; and Dr. J. Allen Wyeth's "Life of N. B. Forrest," the brilliant cavalry leader of the Confederates, is one of the most valuable contributions to the Inter-States War we have seen. It is furthermore a most carefully-prepared biography and most impartial record of a great life. The author's hero stands forth from the canvas, no fault overlooked, no virtue exaggerated—a great man, worthy of an excellent biography.

YET another of the "Golden Rules" series (John Wright, Limited, Bristol), the subject this time being Psychiatry, the text being furnished by Dr. J. Shaw, of the Grove Hall Asylum. Briefly treated under the four heads, diagnosis, prognosis, treatment, and certification, we have a valuable series of hints and suggestions for dealing with the insane. These will be found very serviceable by the general practitioner, whose experience in this department is necessarily somewhat limited, especially as advice is added in respect of the legal position of patients requiring to be certified. This little volume will certainly add to the popularity of the series, and should take its place alongside of the "What to Do in Cases of Poisoning" in the practitioners library of reference.

THE 1900 edition of the "Formulaires des Médicaments Nouveaux," by H. Bocquillon-Limousin (Baillière et Fils, Paris) brings the work well up to date by the inclusion of the most recent additions to the domain of therapeutics. The list of additions is too long for mention, and we must confess that few, if any, of them are familiar to us, or indeed, known even by name. A little work of this kind is just what the busy practitioner requires, and we regret that it is in a foreign language, which must limit its usefulness in this country. We cannot shut our eyes to the progress that is being accomplished in pharmacy and what we may call pharmaceutical therapeutics, but it is often difficult to put one's finger on the requisite information at the right moment. This work enables us to do so.

QUITE a model of what a student's journal should be is the last issue of "The Broad Way," published by the Westminster Hospital students. The scientific side of the journal is furnished by an important paper by Sims Woodhead on "Natural Protective Agencies against Specific Infection," being the Sturges Lecture attached to the Westminster School. Of the rest of the text a good deal naturally deals with things of special interest to Westminster men. The frontispiece cleverly depicts Mr. Stonham, surgeon to the hospital, riding in armour on a steed caparisoned and trapped with a host of saws, syringes, forceps, lithotrites and other surgical *armamentaria* in the Lord Mayor's procession. As a production of students alone and unaided the January number of "The Broad Way" is decidedly in advance of anything of the kind that has come under our editorial notice.

THE double section of the "Oxford English Dictionary," published this month, includes words from Glass-coach to Graded. The section is edited by Mr. H. Bradley. It contains 1864 main words, 588 combinations explained under these, and 578 subordinate entries; in all 3030. The obvious combinations, recorded and illustrated by quotations, but not requiring individual explanation, number 645 more. Comparison with Dr. Johnson's, and some more recent dictionaries, shows the following figures:—As evidence of the enormous increase of words over any other dictionary hitherto published may be here recorded that in this section alone from Glass to Graded, 3,675 words are recorded, whereas in Johnson there are 313, in Cassell's 1565, in the Century Dictionary 1875; whilst the number of illustrative quotations, here are 15,816 against Johnson's 1102, Cassell's 1047, Century Dictionary 1907.

ONE of the most fascinating medical autobiographies ever written is that of the late Dr. Arthur Hill Hassall. As an investigator, worker, and writer, his period of active life extended over nearly sixty years. His early tastes were in the direction of natural history, and led to the study of zoophytes, about which little was known at the time. His chief work was on the adulteration of foods, upon which he became the greatest living authority, and his labours led to the appointment of a Parliamentary Committee of Inquiry and later to legislation. After a serious illness in 1886, he went to Ventnor with so-called fibroid phthisis of one lung. There he founded the well-known Hospital for Consumption, and on leaving in 1887 he was presented with a service of plate, and a purse of 330 guineas. Shortly afterwards he left for San Remo, where he passed the rest of his days.

MM. BAILLIÈRE ET FILS, of Paris, publish two monographs presenting a certain interest, one on non-diabetic glycosuria, by Dr. Roque, and the other on the diagnosis of diseases of the cord, by Dr. Grasset. The former deals with more or less permanent forms of glycosuria which requires to be distinguished from diabetes proper. These forms all present the common characteristic of never being "idiopathic," but, on the contrary, secondary and merely symptomatic. Dr. Roque describes four varieties of this kind of glycosuria and discusses the appropriate treatment of each. Dr. Grasset's little work is an excellent guide to the exact diagnosis of disease of the spinal

cord by physiological observation. Given a patient presenting symptoms of a spinal lesion, how are we to locate the seat of the lesion, and determine what system or systems are mainly, or exclusively, involved? These are the questions which Dr. Grasset sets himself to reply to, and he has succeeded to a great extent in doing so within the limits of this short monograph.

Laboratory Notes.

BYNO-GLYCERO-PHOSPHATES.

WE have received from Messrs. Allen and Hanbury, Limited, a sample of Byno-Glycero-Phosphates. This is a combination of the popular glycerophosphates with bynin liquid malt, and the result strikes us as being extremely satisfactory. With the tonic and reconstituent effects of the glycerophosphates, we get the nutritive and digestive action of the bynin, an association of properties well calculated to prove of service in the treatment of persons suffering, or recovering from, debilitating and emaciating diseases, and generally in conditions of mal-nutrition and debility. The mixture is quite palatable, and is not likely to be objected to even by fastidious patients.

CULINARY DELICACIES.

MR. VICTOR BENOIST, the well-known manufacturer of invalid and dietetic foods, of 36, Piccadilly, has submitted to us samples of his "Consommé de Volaille" and "Turtle Soup." The palatableness of such products is of even greater importance than their alimentary value, but while both must take first rank among culinary delicacies, it is hardly necessary to point out that a "Consommé de Volaille" prepared by skilled hands is an ideal article for invalid dietary, though it is sure to be highly appreciated even by those whose health leaves nothing to be desired. The Turtle Soup is not less commendable and is certainly not less satisfying. It is important to know that these products can be obtained without difficulty in hermetically sealed jars, practically ready for use, in any part of the country. Their keeping properties are remarkable, indeed we are not prepared to assign a limit, never having alighted on an unfavourable specimen.

ANTI-KAMNIA AND CODEINE.

"ANTI-KAMNIA" is the pharmaceutical name of a product briefly described as "a new synthetical coal-tar derivative of the series $C_{20}H_{22-6}$ into which the amines have entered," and elsewhere as having for its base "the derivatives of the amido-benzoles." It is introduced as a powerful analgesic for the suppression of the symptom pain of neuralgic and rheumatic origin. It is specially claimed that it does not exert any depressing influence on the cardiac function.

We have received a sample of tablets containing anti-kamnia in association with codeine in the proportion of 4.75 grains of the former, and .75 grain of the latter. This combination is recommended as being well calculated to subdue pain in cases where a pure analgesic fails to afford complete relief, as in muscular spasms, asthma, &c. The tablets are best given one at a time, at intervals of about half an hour, until three or four have been administered. The relief given in certain cases has certainly been well marked though in view of the small quantity of codeine present the effect was probably due in major part to the anti-kamnia constituent. Our experience has not been sufficiently extended to allow of a comparison of its efficacy with that of analogous drugs, or combinations of drugs, but, after all, what the patient requires is relief from suffering, and not a more or less accurate estimate of the comparative effects of the constituents.

What is an Adequate Salary?

If a medical man of special competence and experience is to devote his whole time to the onerous and responsible duties attached to the post of medical officer of health it is obvious that a sufficient salary must be provided to enable him to live in comfort and independence. The Local Government Board are of opinion that for a

town the size of Scarborough, an annual remuneration of not less than £500 should be allocated, but the Corporation have just reiterated their view, already expressed, that £375 should suffice. Surely this is a very shabby attitude for the governing body of a flourishing health resort to take towards an officer, whose services are of special value and importance in such a town! We trust that the larger-minded members of that body will reconsider the matter, and so put an end to a very undignified dispute, the more so as the Corporation is certain to give way ultimately.

Small-Pox in London

THERE has been a sudden accession during the past week to the numbers of small-pox patients under treatment at the Isolation Hospitals of the Metropolitan Asylums Board. Some seventeen persons are now under treatment, and it is worthy of note that two of them were originally certified to be suffering from scarlet fever. One of these proved to be the victim of hæmorrhagic variola, and has since died. Occasional errors of this kind are quite unavoidable in the early stages of the disease, but the usual mistake is to describe it as measles. Arrangements have been made for any future cases to be received at the Gore Farm Lower Hospital.

Fraudulent Brandy.

LAST week a West-End grocer was fined twenty guineas for selling as "Three Star Brandy" of an eminent firm spirit which he had bought at a sale, bottled and placed labels on of a fraudulent description. Messrs. Martell and Co. have found it necessary to warn the profession and the public to be on their guard against the selling of inferior brandies, which in most cases are not grape spirit at all, in bottles bearing an imitation of their well-known blue and silver label, and the filling-up of their own empty bottles with other brandies. In buying a bottle care should be taken to see that the blue capsule is intact.

A Well-Merited Protest.

MR. THOMAS BOND, the well-known police surgeon, recently made a public protest as to the treatment of bodies recovered from the Thames. He informed the Coroner that the body had been left lying on the steam-boat pier, covered only with a coat, the police declining to remove it until the overseer had been communicated with. It seems that there is an antiquated rule, dating from the reign of George III., enjoining this course; but it should have been sufficient, one would imagine, to call attention to this anachronism for the rule to be modified or abolished, in the interest of public decency.

Liverpool Medical Institution.

At the annual meeting held January 11th the following list of office-bearers and committees were adopted; those marked * did not hold the same office last year:—President: *Edgar A. Browne, F.R.C.S. Ed. Vice-presidents: A. Bernard, M.B., T. B. Grimsdale, M.B., *T. R. Bradshaw, M.D., and *W. Thelwall Thomas, F.R.C.S. Hon. treasurer: *H. Briggs, F.R.C.S. Hon. general secretary: J. M. Hunt, M.B. Hon. secretary to ordinary meetings: *John E. Gemmell, M.B. Hon. librarian: W. Termewan, F.R.C.S. Council: W. Alexander, F.R.C.S., R. A. Bickersteth, F.R.C.S., T. M. Dawson, M.R.C.S., A. Burns Gemmell, M.B., J. J. O'Hagan, M.B., *A. M. Paterson, M.D., *W. Macfie Campbell, M.D., *James Armstrong, M.B., *Owen Bowen, M.R.C.S., Andrew Stewart, L.R.C.P., *W. T. Clegg, M.R.C.S., and *J. C. M. Given, M.D. Auditors: *A. Burns Gemmell and Charles G. Lee, M.R.C.S. Pathological and microscopical committee: J. H. Abram, M.D., F. H. Barenelt, M.D., R. A. Bickersteth, F.R.C.S., *R. J. M. Buchanan, M.D., A. W. Campbell, M.D., F. C. Larkin, F.R.C.S., C. Macalister, M.D., G. P. Newbolt, F.R.C.S., Frank T. Paul, F.R.C.S., and C. S. Sherrington, F.R.S. Journal committee: The Hon. Secs. to Ordinary Meetings and Pathology Section, F. H. Barenelt, M.D., S. B. Grimsdale, M.B., F. C. Larkin, F.R.C.S., Charles G. Lee, M.R.C.S., C. J. Macalister, M.D., G. P. Newbolt, F.R.C.S., and W. Termewan, M.D.

Notices to Correspondents, Short Letters, &c.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

LOCAL REPORTS AND NEWS.—Correspondents desirous of drawing attention to these are requested kindly to mark the newspapers when sending them to the Editor.

READING CASES.—Cloth board cases, gilt lettered, containing twenty-six strings for holding the numbers of THE MEDICAL PRESS AND CIRCULAR, may now be had at either office of this journal, price 2s. 6d. These cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

ORIGINAL ARTICLES OR LETTERS intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

REPRINTS.—Authors of papers requiring reprints in pamphlet form after they have appeared in these columns can have them, at half the usual cost, on application to the printers before the type is broken up.

X. B. (Bradford).—The Colonial Office has at last officially recognised the Liverpool School of Tropical Medicine. Seeing the enterprise and good work which this school has already evinced, such recognition could not have been longer delayed.

EDINBURGH STUDENT.—The formation and gelatine method of mounting pathological specimens yields beautiful results, but the objection to it is that it is too costly.

SPEE.—The procedure is not in accord with the ethical rule of the profession.

THE HALO OF AFFIXES.

The members of the American Medical Association are entitled in future to append to their names the letters M.A.M.A., which looks endearing, but if properly interpreted merely indicates membership. How our American *confreeres* must envy us the large and varied assortment of letters to which we, or some of us, take as a right! A simple M.D. isn't it with the possessor of a large portion of the alphabet tacked on to his family name.

Meetings of the Societies and Lectures.

WEDNESDAY, JANUARY 17TH.

SOCIETY OF ARTS.—8 p.m. Mr. A. Rigg: Ventilation without Draughts.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN (Leicester Square).—At 4.30 p.m. Dr. T. D. Savill: "Pustular Diseases" (Post Graduate Course).

THURSDAY, JANUARY 18TH.

HARVEIAN SOCIETY OF LONDON (Stafford Rooms, Tichborne Street, Edgware Road).—8.30 p.m. Annual General Meeting and Conversazione.

ROYAL INSTITUTION.—At 3 p.m. Dr. Rivers on "The Senses of Primitive Man."

WEST-END HOSPITAL FOR DISEASES OF THE NERVOUS SYSTEM.—At 5 p.m. Clinical Demonstration. Dr. Harry Campbell: "Cases of Locomotor Ataxy, and other Disorders of the Gait."

FRIDAY, JANUARY 19TH.

EPIDEMIOLOGICAL SOCIETY OF LONDON (11 Chandos Street, Cavendish Square, W.).—8.30 p.m. Meeting.

ROYAL ACADEMY OF MEDICINE OF IRELAND.—Surgical Section. The exhibition of cases and demonstrations thereon. The cases will be as follows:—Mr. H. G. Croly: Tracheotomy for Epithelioma of the Epiglottis and Larynx. Mr. Lentaigne: Resection of Goitre by aid of Local Anæsthesia by Cocaine. Mr. MacArdle: Three Cases of Resection of Intestine. Mr. Swan: Foreign Body in the Knee-Joint Demonstrated by the X-rays and removed by Section of Patella. Mr. Heuston: Ligation of Subclavian Artery for Axillary Aneurism. Mr. Chance: Ligation of Popliteal Artery for Aneurism.

Vacancies.

Brecon Infirmary, South Wales.—Resident House Surgeon, unmarried. Salary £90 per annum, with furnished apartments, board (all food except beer), attendance, fire, and gas.

Catholic University Medical School.—Lecturer on Dentistry. Applications to Registrar, Medical School, Cecilia Street, Dublin. (See advt.)

City of Dublin Hospital.—Annual Election for Resident Medical Officers. Applications to Honorary Secretary of Medical Board, Mr. G. Jameson Johnson, F.R.C.S.I. (See advt.)

Dundee Combination Poorhouses and Hospital.—Resident Medical Officer. Salary £100 per annum, with board and furnished apartments. Apply to the Clerk of Council, Dundee.

Glamorgan County Asylum, Bridgend.—Junior Assistant Medical

Officer, unmarried. Salary £150, with board, apartments, washing, and attendance.

Grove Hall Asylum, Bow, London.—Junior Assistant Medical Officer. Salary £120 a year, with board, apartments, washing, and attendance. Personal application to Medical Superintendent desirable.

Nottingham General Hospital.—House Surgeon for two years. Salary commencing at £100, with board, lodging, and washing.

Northampton General Infirmary.—Assistant House Surgeon, unmarried. Salary £100 per annum, with furnished apartments, board, attendance, and washing.

Plymouth Borough Asylum.—Assistant Medical Officer, unmarried. Salary £125 per annum, with furnished apartments in the Asylum, board and washing free.

St. George's Hospital, London.—Curator of the Museum and an Assistant Curator. Salary £100 for the Curator, and £50 a year for the Assistant Curator.

St. Mark's Hospital for Fistula and other Diseases of the Rectum, City Road, London.—Honorary Physician. Also House Surgeon for not less than six months. Salary £50 per annum, with board, lodging and washing.

Torbay Hospital, Torquay.—House Surgeon. Salary £100 per annum and £5 for nurses' lectures. Board, lodging, washing, and attendance provided (wine, spirits, and beer excepted).

West Kent General Hospital, Maidstone.—House Surgeon, unmarried. Salary 100 guineas per annum, with board and residence, &c., rising 10 guineas a year to 120 guineas.

Whitehaven and West Cumberland Infirmary, Whitehaven.—House Surgeon. Salary £120 per year, and £30 a year for dispensing, with furnished apartments and attendance.

Appointments.

Bailes, Norman Christian, M.B., B.S.Durh., Resident Surgeon to the General Dispensary, Birmingham.

Blandford, L. J., M.B., B.S.Durh., House Surgeon to the Royal Infirmary, Newcastle-on-Tyne.

Dyer, S. Reinald, M.D.Bru., M.R.C.S., L.R.C.P.Lond., D.P.H., Medical Officer H.M. Prison, Stafford.

Field, A. T., M.R.C.S., Medical Officer for the Wymondham Sanitary District of the Melton Mowbray Union.

Goffe, E. G. L., M.B.Lond., L.R.C.P., M.R.C.S., Assistant Medical Officer at the Lewisham Union Infirmary.

Gofton, Edward, M.B., B.S.Durh., Assistant House Surgeon to the Royal Infirmary, Newcastle-on-Tyne.

James, M. B., M.B., Ch.B.Vict., Assistant Medical Officer for the Workhouse and Infirmary of the parish of St. Mary, Islington.

McConnell, Jas., M.B., B.S.Durh., House Surgeon to the Royal Infirmary, Newcastle-on-Tyne.

MacGowan, J. S., M.D.Lond., M.R.C.S., Medical Officer for the Fifth Sanitary District of the Township of Oldham, Oldham Union.

Morrison, R., L.R.C.P., L.R.C.S.Edin., Medical Officer for the Duffell Sanitary District of the Belper Union.

Muirhead, Jas., M.B., B.S.Durh., Junior House Physician to the Royal Infirmary, Newcastle-on-Tyne.

Norton, J. J., L.R.C.S., L.K.O.C.Irel., Medical Officer for the Alrewas Sanitary District of the Lichfield Union.

Rowland, Frank, L.R.C.P., L.R.C.S.Edin., Resident Surgeon to the Birmingham General Dispensary.

Scott, Norman E. H., M.B., Ch.B.Glasg., House Physician to the North-Eastern Hospital for Children, Hackney.

Simpson, Wm., M.B., B.S.Durh., Senior House Physician to the Royal Infirmary, Newcastle-on-Tyne.

Young, A. G., M.B., C.M.Glasg., Medical Officer for the Castle Bytham Sanitary District of the Bourne Union.

Births.

CALTHROP.—On January 10th, at Fernbank, Cross Hills, Yorkshire, the wife of Gordon Calthrop, M.B., B.C.Camb., of a daughter.

COOPER.—On January 14th, at 20, Belsize Road, Hampstead, the wife of Ernest F. Cooper, M.R.C.S., of a son.

DODS.—On January 8th, at 24, Marylebone Road, London, N.W., the wife of Louis F. Dods, L.S.A., of a daughter.

LOWSELY.—On January 10th, at 36, City Road, London, the wife of L. D. Lowseley, L.R.C.P., M.R.C.S., of Hampstead Norris, Berks, of a son.

SANDERS.—On January 6th, at Villa Nina, Cannes, the wife of Gordon Sanders, M.D., F.R.C.P.Ed., of a daughter.

Marriages.

ROGER-SMITH-WOODD.—On January 10th, at the parish church, Old Hollington, near Hastings, Hugh R. Roger-Smith, M.D., M.R.C.P., third son of Professor Roger-Smith, of University College, London, to Dorothy Eugenia, third daughter of the late Rev. Basil R. Woodd, Vicar of Bilton, Harrogate.

WATSON-BARRETT.—On January 3rd, at St. Luke's Chapel in Norwich Cathedral, Charles R. Watson, M.D.Bru., of Tunbridge Wells to Grace Elspeth, daughter of Rev. Canon Barrett, of Lincoln.

Deaths.

CULLEN.—On January 4th, at his residence, Cheltenham, Deputy-Surgeon-General David Cullen, Army Medical Department, retired.

GRANT.—On January 3rd, at 3, Connaught Square, Hyde Park, London, Alexander Grant, F.R.C.S., Surgeon-Major, late of the Bengal Service, and Honorary Surgeon to the Queen, aged 82,

The Medical Press and Circular.

Original Communications.

THE CO-RELATION OF SEXUAL FUNCTION WITH INSANITY AND CRIME. (a)

By H. MACNAUGHTON-JONES, M.D.,
M.A.O., M.Ch., &c.,

President of the British Gynaecological Society.

IT is customary for the outgoing President to make a few observations on some topic of gynaecological interest before leaving the Chair. I am influenced in the selection of the subject I am about to bring before you as much by the feeling that the operative side of gynaecology has been so frequently before us of late, that we may well divert our attention to a brief consideration of a gynaecological matter of interest which has nothing to say to operative methods and technique. I refer to the co-relation existing between the discharge of sexual function in women, mental alienation and criminal acts, as also to the bearings of gynaecological knowledge on a few important questions in forensic medicine. Here I must premise that our knowledge of the phenomena that correlate the functional activity or abeyance of action of the female sexual organs, with either transitory or permanent psychical consequences, especially those of a morbid nature, is not sufficiently definite to enable us to draw very accurate conclusions, or to formulate precise axioms, on which we can found principles of practice. On the other hand, experiences have been accumulating which offer most valuable suggestions in regard to the attitude which has to be taken to women at certain periods of their active sexual life, and which also help us by throwing a side-light on the many reflected nervous disturbances in organs remote from the sexual centre.

We may thus, not without profit, reflect on these points. How far does the process of menstruation, including in that term the physiological changes that take place in the ovaries and Fallopian tubes, as well as those which, either associated with, or apart from these, occur in the uterus, affect a woman, by originating morbid impulses in the various groups of her pelvic nerves which find their response in reflected neuroses in other organs, and thus influence the coherence and stability of her mental acts? Or again, in what directions, and to what extent, does the normal fulfilment of ovulation with menstruation develop for the time being erotic impulses, encourage the state of neurosis generally, or so lower both the psychical and physical inhibitory control as to lead to a hyper-exaltation of the nervous system generally, with increased susceptibility to slight irritations (from whatever source they may arise), and a weakened will control that permits of distorted mental visions and erratic moral acts, vulgarly called

crimes, that the woman is helpless to evade or to subdue?

In order to see to what extent this is true, we have to inquire whether there be evidence that menstruation, both normal and abnormal, does so influence the woman, and under what condition it is most likely so to do. The second division of the subject brings us to a very different question, and that is, how far disease of the sexual organs in women is co-related with symptoms of alienation from slight interferences with their mental equilibrium to more profound disturbances such as melancholia, dementia, or mania. This investigation naturally leads to the further inquiry, how far removal of the diseased organs by operation is salutary or otherwise to the woman, and to what extent the operation in itself may mitigate on the one hand, or, on the other, increase the mental trouble.

There are incidental matters connected with anomalies in the formation of the genitalia in women which have a bearing both on gynaecology and psychology, and which have also to be considered in looking at a case from the point of view of a student of forensic medicine. Lastly, there are a few questions of grave import in the elucidation of criminal acts, in the fixing of indisputable guilt, or in the protection of the innocent. Here, again, gynaecologists are brought into close touch with medico-jurists, and the responsibility is a grave one, for there are certain pathological points that the expert gynaecologist is the most fitting person to give a decisive opinion upon.

Before speaking on the questions to which I have referred, there are, it is necessary to remind you, two lines of thought which we should follow in approaching the question of sexual function in the rôle of insanity or crime. In the first place, we now know the intensity of the physiological function discharged not only by the ovaries, but by the Fallopian tubes and uterus, before a menstrual act is completed. In healthy women there is a cycle of changes in the round of which we have a series of nutritive processes, elaborated through the healthful interchange of function on the side of the circulatory current on the one hand, and the tissue and nerve-elements on the other. These processes cause alterations in the circulation of the Fallopian tubes, and the quantity of blood that they contain; the extraordinary changes which take place during ovulation in the ovary, resulting not only in the maturation and bursting of the follicle, but in a general enlargement of the organ and increase in the size of its blood-vessels; these phenomena being associated with, and followed by, equally marked changes in the uterine endometrium, and, in fact, in the entire uterus. All these alterations occur with a periodicity, and such slight outward evidences of their progress and completion, that there is no other physiological process of equal magnitude attended by such important pathological changes as those of ovulation, and yet so slight an apparent constitutional systemic disturbance.

(a) Valedictory Address delivered to the British Gynaecological Society, January 11th, 1900.

Also, we must remember that ovulation occurs independently of menstruation, and *vice versa*, and that even rhythmical menstruation may occur without ovulation; Pflüger, adopts the theory of a dynamic equilibrium of all the organs, from which it follows that the ovaries carry daily a definite number of stimuli to the central nervous system. At any rate, it is certain that the process of ovulation may go on quite independently of menstruation, and that, in fact, a period of about two days generally intervenes between the bursting of a follicle and the latter.

During all these changes in the genitalia there is a co-existing excitation of the ovarian nerve, causing reflex excitations in the uterine arteries, and, as Rohrig says, such ganglionic and nerve excitations proceed through duly provided paths. (a)

Experiments have shown how important is the effect of the secretion of the ovarian gland on the entire economy, and its normal metabolism. It would seem from the experiments of Curatullo and Tarulli (b) that, if it be suppressed the elimination of phosphorus is diminished, as also the respiratory changes are seriously influenced, while, owing possibly to a faulty metabolism, the body weight is increased. How great an effect the ovaries must have on metabolic phenomena, is, perhaps, best shown by the cure of osteo-malacia by oöphorectomy, an affection which Fehling has attributed to exalted ovarian functional activity and consequent reflex effects on the vasodilators and constrictors of the medulla. (c) The disease is, according to him, a reflex tropho-neurosis of the skeleton, having its focus of reflection in the ovary. Schauta and Mary Dixon Jones (d) have also recorded cases of cure of osteo-malacia by removing the ovaries, and the physiological effects of the constant pouring into the system of this secretion, is, according to Fehling, increased oxidation of organic phosphorised bodies, as well as hydrates of carbon and of fats. If, therefore, the ovaries are removed, or if their function is in abeyance, organic phosphorus is retained, and there is an increase in the calcareous salts in the skeleton. To follow up the various bearings of these physiological effects of ovulation, and the ovarian secretion, either through undue activity or diminution in quantity, would in itself occupy all the time at my disposal. Even the little knowledge we possess of the powerful effects of the unstable phosphorus compounds of the protagon and lecithin series on metabolism throughout the entire body, but more especially on cerebral, cerebro-spinal, and sexual impulses and excitations, is sufficient to indicate how great must be the influence of a secretion like that of the ovary on the entire nervous system, from the parts involved in the excitation of lower and higher reflexes to those portions of the brain cortex in its anterior lobes, which have, as Clouston says, "mentalisation as their function, and which are unquestionably the examples of the highest evolution of organised matter to be found in nature, the fullest of hereditary qualities, the most powerful, yet the most unstable, and by far the most physiologically valuable, part of man—the vehicle of the goodness of the saint and the badness of the criminal." Curious fact for reflection, that, as Hinton long since pointed out, where all this evolution of thought and will exists, there is no textural scaffolding, instability of structure having for its counterpart instability of organic material, and ever fleeting, changing, and mystic mentalisation, acknowledging no definite or stable scheme for its elaboration of the mandates that it issues.

Also worthy of reflection is the fact, that while in the organs endowed with the highest vitality for sexual function and on the parts concerned in generation and the propagation of the species, we find this instability of organic constitution in the male and female secretions, so do we find the same organic instability in the constitution of the highest centres in which reside thought and will.

"There is no doubt," says Claye Shaw, (a) "that the sexual is an innate faculty of the brain stronger in some than in others, and one whose existence is possible without any correspondence of external organs." If this be true, then how much of sexual crime has its origin in defective or abnormal mental organisation?

This brings us to the recognition of all that mass of work which has been done of recent years, and which has served to prove that physical configuration, deviations from the normal physical type, evidences of defective evolution in the growing youth, combined with the legion of hereditary transmissions in which we have defective evolution, physical and mental, exist in one direction, while concurrently there appears to be an excessive distorted or diminished hyper-development of certain traits and configurations in the other.

If the researches of the school of Lombroso and his workers be true, and that physical configuration, not only in the higher centres of nerve structure, but in co-related physical deviations from the normal type, are indications of perversion in the moral and mental attributes of the person exhibiting them, how likely is it to be equally true that anomalies in development, and structural straying from the normal type, as well as pathological changes occurring in the sexual organs of a woman (organs from which emanate impulses and excitations, stirring the deepest depths of her moral nature), have a direct relationship to those motives and actions which we so flippantly embrace under the head of "criminal." If one of our duties as gynaecologists be to study the correlations that exist between the correct discharge of functions on the part of women's sexual organs, and the various morbid impulses set in motion, both physical and mental, arising from congenital or acquired histological and pathological changes in her sexual organism, including the many paths of sexual expression and impression involved by these, then, surely, gynaecologists are brought into the closest relationship with the springs of action which must throw light on criminal motives and criminal deeds.

"If," says Clouston (b), "we take the twelve years between thirteen and twenty-five as the average period of adolescence, it is in the latter six that most criminals develop into that condition. The maximum of criminality falls after twenty-five. By far the greater part of the habitual criminal become so, in fact, before the moral inhibitory faculties have attained full physiological perfection." And he goes on to say, "There is one kind of temptations then strongest, and these are connected with the sexual natus." It is at this age of life, as he insists, that criminals become so, while there is lack of development in their cerebral qualities, their intellectual, and their reasoning powers. This deficiency is associated in those centres, where, while in their highest form of development, we have instability in function and an apparent lack of textural homogeneity, there is still that mystic yet harmonious union of mental impulses with moral inhibition.

"Each with each in turn blending,
Each on each in turn depending."

"(a) On Insanity with Sexual Complications." By T. Claye Shaw, M.D. St. Bartholomew's Hospital Reports, Vol. xii.

that marks the moral and mental stability of the man or woman.

I have to abandon all idea of statistics in a short paper like this, and must be satisfied with referring to certain proved and established facts which bear on the relationship that exists between anomalies of development and pathological changes in the sexual organs of women, and perverted mental and moral impulses.

In the first place, we find such minor troubles present in a large proportion of women who have pathological changes in the uterus or adnexa, associated or not with congenital irregularities or deformities in conformation, as aggravated headache, sense of distension in the head, interferences with memory, facial neuralgia, migraine, ocular and laryngeal, with aural vertigo and tinnitus, symptoms of hyperæsthesia or anæsthesia of the extremities, spinal irritation, true hysteria, insomnia, anosmia or perversions of smell, general neuroæsthenic conditions as agorophobia, cesophageal spasm, gastralgia, and such a neurosis of the coccygeal nerves as painful sitting. Disturbances of the pneumogastric and splanchnic nerves are shown by gastralgia, with various dyspeptic symptoms, while the disturbance of the nerve control of cardiac rhythm finds its expression in intermittent or exaggerated action of the heart and dyspnoea. Such conditions we may class under the general head of visceral and various reflected neuroses, which owe their origin to perverted impulses starting from abnormal or diseased states of the genital organs.

Graver consequences are noticed in epilepsy and hystero-epilepsy, in melancholia, suicidal insanity, and dementia. Piqué found a proportion of 88 per cent. of gynecological affections among the insane, and others have found them in even higher proportion than this. He arranged his statistics from sixty six cases, according as the disease of the brain developed contemporaneously with that of the womb, those with serious genital affections, where operation had but a comparative success, and those whom operation benefited, hastening their recovery. There was definite cure in eleven cases.

We can hardly doubt, with A. T. Hobbs, that constant irritation of the lower nerve centres, incidental to local disease, must react upon the higher centres, and the effects recorded by several observers have to be given due weight in the consideration of the question as to whether insanity has been cured by the ovarian secretion. I have had some interesting evidence from Christopher Martin in the same direction, and Arthur Wilcox has treated several cases of insanity by the administration of ovarian extracts. In cases of suppressed menstruation, in which this was given, distinct recovery took place from such conditions as melancholia and mania. It was not so successful in epilepsy. Jacobs of Brussels has reported similar cases. Hobbs further found that one-sixth of the females in the Ontario Asylum suffered from diseases of the generative organs. Of 110 cases operated upon, 65 were either completely restored (36) or improved by operation (29), and the cases published by Holmes of Chatham (Ontario), Burgess of the Protestant Hospital for the Insane at Montreal, and many other writers, establish the fact of the correlation that exists between diseases of the pelvic viscera in women and insanity. If we look into the nature of the affection most likely to produce mental disturbance, we find it most common in disorders of menstruation, which of course may have as their cause various pathological conditions. With amenorrhœa and dysmenorrhœa we frequently find abnormal congenital configuration of the uterus and affections of the ovaries and Fallopian tubes. The affection of the ovarian nerves which Mary Dixon Jones has so accurately described as "gyroma," she

has demonstrated to be present in many cases of epilepsy, and the removal of the diseased ovaries has effected a cure in several cases not only of epilepsy, but of osteo-malacia. There are instances on record in which tubercle, carcinoma, and endothelioma were present in the removed organs. While time does not allow any lengthy reference to a record of cases, the names of the writers are sufficient guarantee in themselves of the reliability of their facts. They have shown that insanity and ovarian disease not only do frequently exist side by side, but that removal of the offending organ relieves the mental condition. Boldt, Felding, Goodell, Beatty, T. G. Thomas, Marion Sims, and Lawson Tait were among the earliest workers in this field. Still, the difficulty exists of establishing the relationship between uterine and adnexal disease and insanity as one of cause and effect.

Kraft Ebbing (a) has entered into a full investigation of the medico-legal relations of disordered menstruation, and he lays down the propositions that in any medico-legal investigation, not only should the mental condition of the woman during her menstrual period be closely investigated and the concurrency of menstruation with the act imputed be noted, but the previous history of her mental attitude during menstruation should be inquired into, and if it be found that menstruation has, as a rule, a decided effect on the ideation of the woman, or that the catamenial epoch be associated with mental disturbance and acts of an impulsive character, these facts should be taken into consideration as extenuating circumstances or the proof of irresponsibility. All evidence goes to prove that the appearance of the catamenia has, in a large number of the mentally afflicted, an important effect on their condition. This, of course, is more manifest in the disorders of the menopause, in which nervous excitations and psychic disturbances, with various hystero-neuroses, occur. And we know that, in addition to the ordinary histological changes in the ovaries and Fallopian tubes which takes place at the climacteric, there are also at this period frequent pathological changes both in the adnexa and the uterus.

A most valuable paper touching on this subject, on "Insanity with Sexual Complications," has been written by Clay Shaw (Bartholomew's Hospital Reports, vol. xxii.), and is well worth perusal by every gynecologist. He rightly dwells on the dual nature of sexual delusions—those that are purely mental, without relation to the sexual organs, and those which have their origin in the latter. He also points out how, even though there be a correlation between the insanity and the sexual centres of the cord, how dangerous it may be at certain times to excite further reflex activity and stimulate those centres. There may be, he says, uterine or ovarian disease without insanity, or a sexual form of insanity without disease of the genitalia, or, thirdly, insanity may exist and no sexual delusions. The great difficulty lies in establishing the cause or effect of sexual disorder and the insanity. It is clear that the mere fact of sexual acts or delusions being present is totally insufficient to do this, and the whole of Clay Shaw's arguments go to prove how difficult, if not well-nigh impossible, it is to establish such causal relationship. Referring to a case in which there were recurrent exacerbations of insanity during the catamenia, the patient being rational on most subjects in the intervals, though of an erotic nature, he says:—"I think that the operation of oöphorectomy would have much relieved her symptoms, at any rate, the violent ones; but of this I could not be sufficiently sure to be able to recommend it. . . . In an acute stage of violent

(a) "British Gynecological Journal," May, 1898.

insanity, anything like a serious operation is," he says, "out of the question, and there is always the probability of acute symptoms coming on after an operation, preventing the rest which is so indispensable. I think that this is just such a case in which an examination in the middle of the interval be justifiable, and if diseased adnexa were found, oöphorectomy should be performed; not otherwise. Seeing the mass of intellectually sound women who suffer from disease of the sexual organs, I think Clave Shaw's conclusion, that true sexual or uterine and ovarian insanity is by no means common, is a correct one; but, on the other hand, this does not invalidate the soundness of the proposition, that a differential diagnosis of insanity in women and the presence of disease of their sexual organs, has to be carefully considered as a primal or sustaining cause of the mental condition.

The expediency or justification for the examination of any insane woman will depend upon the answer to the question, not whether her insanity is sexual or otherwise, but if the assertion be true that the primary cause of the alienation may rest in a pelvic disorder, which it is the duty of those who have her in charge to discover. Dr. Clave Shaw speaks highly of the effect of wet cupping over the loins in cases of epileptiform insanity at the time of the catamenia. It has the advantage of directing the attention of the patient away from, rather than to, her sexual organs.

(To be concluded in our next.)

Clinical Lecture

ON THE

ROLE OF THE PHYSICIAN IN RENAL AFFECTIONS.

By PROFESSOR LANCEREAUX,

Of the Faculty of Medicine of Paris.

HAVING for function to eliminate from the economy the greater part of the products of tissue waste, many of which are extremely toxic, the kidneys play so important a part in the mechanism of life that if any serious impediment to their functions supervenes, the immediate result is poisoning and death. Consequently the physician should always bear in view the way in which these organs fulfil their function, not only in the course of affections peculiar to them, but in all maladies both acute or chronic for there are very few of the latter which do not, in one way or another, affect the kidney. In every case, then, and under all circumstances, the physician finds himself in presence of two special indications which never vary:—

Treat the renal lesion or functional trouble,

Treat the intoxication which is the consequence of the affection.

We will leave on one side traumatism, parasites, and tumours of the kidney, and even acute idiopathic nephritis. Every variety of nephritis, all these complex groups of symptoms which have been classed in general under the term Bright's disease, albuminuria, acute or chronic, are always symptomatic. Always and invariably, the primary malady localises its effects at the outset to one only of the anatomical elements composing the kidney. In fevers for instance, the epithelium alone suffers. In tertiary syphilis, saturnism and herpeticism it is the vascular connective tissue which is affected, the cells only becoming involved later on.

Hence we have two classes of nephritis, epithelial and connective tissue, which differ from each other in respect of their symptoms, their evolution, and their prognosis. This is the point which I wish to discuss on the present occasion, for this anatomical duality necessarily entails a therapeutic duality

Consequently, when called upon to treat a renal affection the physician must first ascertain the exact nature of the disease before venturing on a prognosis and employing a rational treatment, that is to say, the treatment proper to the histological element affected. Thus, in epithelial nephritis where the detached epithelium obstructs the ducts, causing almost complete suppression of urinary secretion, cantharides, which acts as a specific on the epithelium, incites the flow of urine after all other diuretics have failed. But you must bear in mind also that a rigid milk diet in these cases is of paramount importance, not only by reason of its diuretic effects but also on account of the necessity of not overtaxing the secretory function of the renal epithelium.

Let us consider on the other hand, connective tissue nephritis or nephritis without primary lesion of the epithelium. The indication is for us to have recourse to an agent capable of modifying the new sclerosed tissue. Preparations of iodine, and iodide of potassium in particular, possess this property. They should consequently be prescribed whenever the connective-tissue stroma is in process of proliferation. The drug should be prescribed in doses of from 15 to 30 grains daily and even more, and that for weeks, months, and even years on account of the tenacity of the affection. Employed at the outset, iodide of potassium sometimes effects a cure, but in the majority of cases the action of the drug is limited to retarding the progress of the disease. Prescribed when the disease had reached an advanced stage, the iodide does more harm than good. But this is not all. In addition to the two kinds of nephritis already described, there exists a third variety in which the structure primarily affected is the nervous element, viz., the so-called neuropathic affection of the kidney. In this malady, opium, antipyrin, and especially quinine should constitute our treatment.

When, in the course of these renal affections, uræmia has set in, the treatment naturally changes, and here also it is necessary to bear in mind the teachings of pathological anatomy and of clinical observation. What does pathological anatomy tell us? It tells us that the lesions of uræmia are focussed on the digestive tract. The other lesions of elimination, that of the skin, the bronchi, and the serous membranes, although present to a certain degree, are, however, not well marked; it is the alimentary canal which is principally affected. The mucous membrane of the stomach is injected, thickened, and sometimes ulcerated, and is always coated with thick mucus; the presence of this mucus produces irritation of the membrane, and is largely composed of the debris which can no longer pass off through the kidneys. The small intestine is but little affected, but it is otherwise with the large intestine, and especially the rectum, which is slate coloured, thickened, covered with mucus, and, in parts, ulcerated.

What does clinical examination teach us? It teaches us that there are two kinds of uræmic symptoms—digestive symptoms and nervous symptoms. The digestive symptoms (vomiting, diarrhoea, &c.) are rather providential; they should be respected and even solicited. We must, therefore, prescribe emetics, especially in the uræmia of fevers. The purgatives must be of the drastic kind, that is to say, such as act more especially on the large intestine. The nervous symptoms (convulsions, headache, delirium, &c.) should be treated by chloral. Nothing equals chloral in the treatment of nervous uræmia, provided it is given in sufficiently large doses. Give it without hesitation and you will never have occasion to regret it.

Such are the general principles of the treatment of uræmia—drastics and chloral. There are, however, other means of treatment which must not be

neglected, one of which I may mention, for I employ it frequently, I am referring to cold affusions. Every morning I order the whole body to be rubbed with cold spirit lotion in order to stimulate oxidation. This treatment is vastly superior to inhalations of oxygen, which, after all, only occupy the mind of the patient, and can do no real good. After the administration of drastics (scammony, jalap, &c.) you have seen me prescribe pills composed of squill, digitalis, and scammony, in doses of one grain each of these substances. From six to eight of these should be given daily for six or eight days.

These pills purge two or three times a day, and increase the quantity of urine. They act rapidly, especially where much œdema is present. If, however, after three days the secretion of urine has not notably increased, the pills should be replaced by the bromide or caffeine.

The regime of the patient should be milk, but occasionally, tea and *café noir* may be permitted.

The Harben Lectures.

DIPHTHERIA.

By PROFESSOR WILLIAM R. SMITH, M.D., D Sc.,
F.R.S.Ed., BARRISTER-AT-LAW.

ABSTRACT OF LECTURE III.

DIPHTHERIA, as I have already remarked, is a disease occasioned by the presence of a particular bacillus, which for all practical purposes is found alone in the affected area and its neighbourhood, and which in the course of growth and multiplication forms a toxin, or poison; and this poison, subsequently becoming absorbed into the system, gives rise to the general symptoms with which we are all familiar.

These toxic products are therefore of the greatest importance. They vary greatly in their composition, and consequently differ in what may be called their lethal activity, and in their local or swelling-producing activity, one specimen containing a considerable proportion of the substance which determines the local effect, but a smaller amount of the substance causing the death of the animal; whilst a second toxin may set up only a slight local reaction but cause death in a comparatively short space of time. In diphtheria it is the lethal action of the poison which has to be reckoned with, and, in the successful treatment of the disease, therefore, the activity of antitoxic serum is determined by ascertaining its power of neutralising this lethal activity as accurately as possible.

In order to determine the absolute toxicity of a toxin Ehrlich took the death period as four days from the day of infection, so that if the animal lived beyond the fourth day, the dose of toxin would be considered sub-lethal. He pointed out that, owing to the varying susceptibility of the animals, the dose might kill some of them in two days, while a certain number of them might live to the fourth day, but if the dose were strong enough, no animal should live beyond that day. Theoretically 100 times this dose, injected along with one unit of antitoxin, should not kill before the fourth day, on which day the animal might die, but it certainly should not live beyond the fifth or sixth day. It was found, however, that this multiple of 100 plus the unit of antitoxin did not give these definite results. He then determined accurately two neutralisation points—first, the amount of toxin which one antitoxin unit exactly neutralises—i.e., the effect on the animal after injection would be such that not only would the animal not die, but no ill-effects would follow. This point he represented at L_0 , nothing being left to be neutralised. The second neutralisation point was that at which the quantity of toxin present is not only sufficient to neutralise the whole of the antitoxin, but a sufficient quantity of uncombined toxin remains sufficient to kill the animal on the fourth day—

this point he represents as L_x . Theoretically the difference between the two L_0 and L_x should be 100 and 101 multiples of the single dose respectively. In the first case there is complete neutralisation, in the second an excess of toxin sufficient to kill the animal in the same time that a single lethal dose would bring about the same result. This method, however, is not in actual practice.

Ehrlich further shows that there is a definite chemical action and reaction between toxin and antitoxin, neutralisation going on more quickly in concentrated solutions than in diluted ones. Heat accelerates and cold retards the combination, and these, it will be noted, are precisely the conditions under which ordinary chemical double salts are formed. He thus was led to look upon the neutralisation of toxins by antitoxins as the formation of a double salt; and arguing from this analogy, he laid down the rule that one equivalent of the toxin always neutralises an equivalent of the anti-substances, and that multiples of the one neutralise corresponding multiples of the other. A molecule of the toxin binds, therefore, a definite and constant quantity of the anti-substances, for which also it has a specific affinity.

A further suggestion by Ehrlich, which is of supreme interest in this connection, is that small quantities of the tetanus toxin are actually selected by the motor ganglion cells of the central nervous system from the fluids in which the toxin is conveyed throughout the body, and firmly held by such cells. Every functional cell consists primarily of a nucleus, associated with which is the main function of the vitality of the cell. In addition there are associated "lateral chains" with subsidiary or special functions. These chains have specific combining functions, one chain especially having a special affinity for the tetanus poison which is literally seized upon by the living protoplasm of the cell, and by this means the lateral chain is subjected to the continued influence of the attached tetanus poison, which—to use Ehrlich's words—"brings about a slowly-advancing, but long-continuing functional disturbance so long as the union of the lateral chain and toxin continues," and this union generally remaining permanent, there is an explanation of the formation of the anti-substances.

This function of the lateral chains to hold the toxin is something apart from the ordinary cell activity. As fresh toxin is presented, so there is induced in the cell a greater and greater power of combining with the toxin, this power assuming a particulate character according as the toxin molecule is that of diphtheria, tetanus, snake-poison, or the like, and as fresh supplies of toxin are provided, new lateral chains are formed, having the specific power of combining with the specific toxin. These chains become developed to such an extent that they can no longer be retained in the cell, but are thrown off into the blood unused, ready to come into contact with the specific molecules for which they have affinity—indeed, under such circumstances they appear to have a greater power of combination than they possessed when present in the cell.

Another interesting point is that even large doses of the toxins, with the exception of the snake poison, require a considerable time in which to exert their toxic effects. Ehrlich suggests that this is because the toxin is forming a definite molecular combination with the protoplasm of the cell or its lateral chain, and that having entered into the combination, it does one of two things, either it paralyses the cell, thus interfering with its main functions, or it so stimulates its special function that, in place of succumbing, it gradually acquires the power of combining with, and rendering harmless larger and larger doses of toxin. In the one case, the death of the cells and the animal occurs; in the other the formation of antitoxin.

Further, Ehrlich asserts that if the special cells of an animal or organ do not possess lateral chains that can unite with the toxin molecule, the toxin does not prove fatal to these cells, and no antitoxin is produced. The obvious bearing of this upon the production of antitoxin by susceptible animals, and the failure of all attempts to reproduce it in animals immune to certain of these organic poisons, is of great interest.

Roux and Yersin obtained the toxin of diphtheria by precipitation with alcohol and phosphate of lime, and therefore looked upon it as a ferment or an enzyme, Brieger and Frankel saw in it a tox-albumin or a mixture of such, whilst Dr. Sidney Martin, in a report to the Local Government Board (on "The Chemical Pathology of Diphtheria and of Infective Endocarditis; with an Account of Diphtheria Palsy, experimentally produced by the Chemical Poison of Diphtheria"), describes how he obtained an albumose and an organic acid from the blood and organs of patients who had died of diphtheria. This albumose is capable of remaining in the blood for a considerable period after a single injection.

If such a toxin be kept in a warm chamber, it begins to lose its toxic effects, while its power to neutralise an antitoxin remains unimpaired. This is an important fact to remember in keeping a test toxin for standardising an antitoxin.

Further, Dr. Cartwright Wood, who had previously pointed out that, in order to artificially obtain the toxins of the microbe formed in the human subject, it was necessary to give it albumin, so as to place it as nearly as possible under analogous conditions to that which pertained in man, obtained an active growth of the bacillus by inoculating broth with a virulent culture, and after the lapse of a day or two he added 10 to 20 per cent. of horse serum, or plasma, in order that the enzyme or ferment toxin produced from the broth might not alone be formed, but also the albumoses from the dilute albumin.

The conclusions which Dr. Cartwright Wood arrived at as the result of this interesting series of experiments with albumoses may be given at length, so important are they in connection with the treatment of diphtheria. They are: "(1) That powerful diphtheria antitoxins can be produced without risk in a much shorter period of time than has been previously possible; (2) that much more powerful antitoxins can be easily produced, so that the amount necessary to be injected into a patient can be greatly reduced, and one of the great objections to its introduction into private practice in this country may be removed; (3) that the greater strength of the serum will permit of the patient receiving at the beginning a sufficient quantity of the serum at one injection, when, as is universally recognised both by animal experiment and clinical experience, its curative action is exerted most markedly."

After these preliminary remarks let us now consider the steps necessary for the preparation of antitoxic serum. The toxin is prepared by the growth of the diphtheria bacillus in nutrient bouillon, prepared by taking a pound of veal, from which all fat and connective tissue has been removed, mincing it, and adding to it 800 c.c. of water, allowing it to stand for two or three hours, and then boiling it for twelve hours, care being taken to keep the meat from running together in masses by shaking it; the fluid is then expressed from the meat in a press, and 2 per cent. of Witte's peptone added; it is afterwards boiled for an hour, allowed to cool, and filtered; it is then heated to the boiling-point, and neutralised or rendered faintly alkaline to phenol phthalein with normal sodium hydrate solution, about 30 to 33 c.c. of normal sodium hydrate solution being required per litre; after neutralisation it is again boiled for two hours, filtered, and transferred to the flasks in which the toxin is to be produced, which resemble a Wolfe's bottle, having three necks; this shape of flask so as to ensure a good surface growth, 400 c.c. of broth are placed in each flask.

The broth is inoculated with an organism, which has been specially chosen for its virulence, and the flask is kept at a temperature of 35 degs. C., or from 30 degs. to 36.5 degs., some bacilli producing a more active toxin at the lower, others at the higher, or at an intermediate, limit. In the course of twenty-four hours a diffuse cloudiness takes place in the liquid due to the formation of dust-like granules or small flakes, which sink to the bottom as a flocculent sediment. The turbidity and sediment increases in proportion to the activity and vigour of the organism; at the same time a film is

formed on the surface which is easily broken up by shaking, when it sinks to the bottom; the opalescence remains as long as the alkalinity of the medium is maintained and growth continues; when this has ceased, the flocculi sink to the bottom, the broth resumes its original clearness, and the formation of toxin ceases, although the bacilli are alive in the sediment; this film-formation is important as an indication of strong toxin production.

If the reaction of an inoculated alkaline broth be tested at intervals, an acid reaction will be noted which increases during the first two or three days after inoculation; then comes a pause, and finally the broth appears to regain its alkalinity; if the broth be acid or but faintly alkaline, no good toxin is produced.

The growth of the pseudo-diphtheria bacillus is also vigorous in broth, but the cloudiness is more dense, sets in earlier, and the broth becomes clear much later; there is also an absence of acid-production in the early days of growth.

The toxin is then poured into properly sterilised jars, where the bacilli rapidly settle in a thick deposit. The supernatant liquid is then at once filtered through a Chamberland filter, and the strength of the toxin, as regards its lethal activity tested, and the result recorded on the flask which contains it.

The antitoxin is obtained by taking a horse, and testing it for glanders and tubercle in the first instance by the use of mallein and tuberculin so as to be assured that the animals are free from these diseases. An injection is then made subcutaneously in the neck of 300 c.c. of the serum toxin; this, according to the amount of reaction obtained, is followed by a similar injection of 400 c.c. in two or three days, and so on persistently for about four weeks. In this way the animal is rendered immune, and then injections of the ordinary ferment toxin may be commenced, 400 c.c. being first used, and then repeated every three or four days, the doses being gradually increased until 500 or 600 c.c. are injected. The blood is carefully tested from time to time throughout the treatment, and in this way it can be determined when the blood is ready to be drawn. This is eventually done by making a small incision through the skin over the jugular vein; slight pressure should then be exerted on the vein below the point of intended orifice, and by thrusting in a trocar, to which is attached a piece of indiarubber tubing, this is arranged to discharge its contents into a sterile beaker of a capacity of 800 c.c., covered with parchment paper, and containing 6 or 7 c.c. of a 10 per cent. solution of citrate of soda. The addition of this salt delays the clotting of the blood, so that the red cells have time to fall to the bottom, by which means an exaggerated buffy clot is formed. At the end of twenty-four or forty-eight hours nearly one-half of the bulk of the blood is drawn off as serum, and if the clot be allowed to stand a day or two longer another 5 or 10 per cent. may be withdrawn. The serum is drawn off by a system of exhaustion into a sterilised conical flask, graduated in half-litres, and to each litre 30 c.c. of a 6 per cent. emulsion of trikresol is added, so as to make the serum an impossible medium for organisms to grow in. The serum in bulk is then transferred to a cool, dark room. No other special precautions are called for, it is then tested and brought up to a proper standard with other antitoxins of known strength, and ultimately sent out in small tubes containing 4,000 units in 10 c.c. for a dose.

The use of antoxic serum for the treatment of diphtheria cases has now for some time been general in the hospitals of the Metropolitan Asylums Board; let us therefore look for the results to the statistical evidence available from these institutions.

I have prepared tables showing the mortality per cent. of the diphtheria cases admitted into all the Board's hospitals for each year since 1889, the first complete year after diphtheria was recognised as a disease admissible to the Board's hospitals, from which we can deduce the following total mortality rates:—

1889	...	...	40.7	1895 (first antitoxin year) ...	...	22.8
1890	...	...	33.5	1896 ...	...	21.2
1891	...	...	30.6	1897 ...	...	17.7
1892	...	...	29.5	1898 ...	...	15.4
1893	...	...	30.4			
1894	...	...	29.2			

by which it will be seen that in 1898 the mortality had been reduced by the use of antitoxin nearly 50 per cent.

At every hospital the rate of mortality fell, the lowest being at the South-Western Hospital, where it dropped from 22.50 in 1892 to 11.96 in 1898.

We find that for every age-group the percentage mortality in 1898 was less than one-half of what it was in the pre-antitoxin period 1890 to 1893.

In a report issued by the medical superintendents of the Metropolitan Asylums Board for the year 1895, the following table appears, which shows the great importance of the treatment being adopted at an early stage of the disease; this we can readily see is in absolute accord with our scientific knowledge on the cause and progress of the disease.

Showing percentage of mortality in relation to day of disease on which cases of Diphtheria came under treatment in the Hospitals of the Metropolitan Asylums Board.

Day of disease.	Mortality per cent.
First	11.7
Second	12.5
Third	22.0
Fourth	25.1
Fifth and over	27.1
Total	22.5

This table is not repeated in the 1898 report.

The benefits derivable from early treatment are clearly shown in this table. But far more striking evidence is obtained from the experience of the serum treatment of post-scarlatinal diphtheria cases, that is, cases of scarlet fever which develop diphtheria whilst in scarlet fever wards. To such cases occurring in the Board's hospitals, the treatment can be applied immediately after the diagnosis of the disease.

From a consideration of the tables which I have prepared, it is manifest that the greatest success attended the treatment of those cases which were at once recognised, and at once subjected to the injection of antitoxin serum.

We have now arrived at the point where we may consider what, if any, practical points we have gleaned which may help us in dealing with outbreaks of this disease.

We naturally ask, how is its continuity maintained in the intervals between epidemics? Is it a sufficient explanation to give that the disease is kept alive by direct infection from one to another by so-called unrecognised cases, or is it not more reasonable to suppose that the germ finds some favourable local habitat such as soil, and that at intervals its virulence becomes increased and a fresh outbreak occurs? But if this be so, then our inquiry is thrown a step further back, for we then have to determine what is the cause of the periodic increases of virulence, or else, assuming there is no variation in virulence, what occasions an attack on human beings? All these questions involve problems of the greatest complexity, which will still further have to be worked out.

The chief cause of infection, so far as our evidence at present goes, is personal contact. Owing to the compulsory notification of disease in this kingdom, there is but little chance of a well-marked case of diphtheria remaining for any time as a source of danger to the community, but there is a danger of mild and unrecognised cases so remaining; such, for example, as when one member of a family has contracted diphtheria, and has infected the other members, these latter being to some extent immune, or has infected others before definite symptoms have arisen necessitating isolation; or,

secondly, among school children when a child has the specific organism in his throat, and infects others before definite symptoms have arisen; or, thirdly, when convalescent patients who have been treated in hospital, are clinically cured, but still retain diphtheria bacilli on their fauces, and are allowed to return to their families.

If it were insisted that no patient should be discharged till the throat were free from the specific germ, it would involve great hardship to the patient, and would put even a greater strain on hospital accommodation than is the case at present. The best thing would seem to be to send each patient, as soon as he was well enough, from the ward tenanted by acute cases, into the country if possible, or at all events into a different department of the hospital, and there, by means of abundance of pure air, aided by local antiseptic treatment, to see if the bacilli would not disappear in a shorter time than occurs in a diphtheria ward.

We have noticed the great incidence of the disease on young children, and the importance of school authorities adopting all proper precautions for the prevention of the spread of the disease through the agency of schools. I have reasons for believing that these are not so rigidly observed throughout the country as they should be, and it would seem desirable that the Education Department should take a more active part in directing school authorities in these matters than they have hitherto done. Questions of the most vital public health interest are continually arising in connection with the aggregation of children in schools, and it would appear a matter of urgent public necessity that for such questions the Education Department should have at its disposal the services of an experienced medical adviser. I know that this Institute has made representations on the subject to the Government, and these it is to be hoped will meet with a favourable response. But the measure of all others which I desire most strongly to urge is the use of diphtheria antitoxin for prophylactic purposes.

The only possible objection to the use of diphtheria antitoxin for prophylactic purposes is liability to the inconveniences occasionally attendant on the injection of the serum arising from the occurrence of rashes and perhaps joint pains. These are due not to the antitoxin, but to the serum itself, normal serums exerting a similar action, and, according to Behring, the smaller the amount of serum injected, the less is the risk of these symptoms occurring. The prophylactic dose, of course, requires only a very small quantity of serum, and Behring suggests that this ought to be reduced still more by the use of the extra potent serums, so as to obviate all risk of the occurrence of such symptoms. As these extra potent serums are not so stable as those of the lower grade, he suggests that they should be sent out in the dry form for this purpose. It is hardly necessary to state that the protection, where necessary (as in the case of nurses, attendants, &c.), can be kept up by repeating the injection every five or six weeks.

By the general adoption of this means, I am certain, the amount of diphtheria would be materially diminished, much suffering prevented, and we should be fast approaching the time when the disease would be altogether removed from our midst.

ON THE THERAPEUTIC VALUE OF SALOPHEN.

By T. POYNTZ WRIGHT, M.R.C.S.E., L.S.A.,
M.O.H.

THE value of salophen as a therapeutic agent in various diseases does not appear to have attracted the same attention in this country, or—till lately—in America, as it has on the Continent, where for some years past it has been viewed with great favour, and where, also, the best results have attended its exhibition in numerous ailments. I am desirous, therefore, of recapitulating some of the experiences that have been obtained from its use, and the nature of the cases treated, with a view to a more extended trial by the profession here.

I pointed out, in a letter addressed to one of the London medical journals nearly a year ago, that one of the principal advantages of salophen lay in the fact that it was a perfect substitute for salicylic acid, and its salts, and that one of its chief claims was that it possesses all the merits of the former drug, with none of its inconvenient after-effects.

It has long been recognised that the various preparations of salicylic acid are among the most reliable remedies for many diseases, but it is also equally recognised that the use of this salt and its compound when long continued, or when exhibited in large doses, frequently produce symptoms, such as vomiting, nausea, headache, buzzing in the ears, or even delirium, which often compel us to discontinue its use, and this before we have effected the object for which it was administered.

Salophen is a combination of salicylic acid and acetylparamidophenol, which is not decomposed by acid, and which passes through the stomach unaltered, and without disturbance. The intestinal alkaline mucus, however, splits it up into salicylic acid, and acetylparamidophenol, but the process is so gradual and slow that the effect of the salicylic acid on the system is much more lasting, and this without any of the disturbances previously referred to.

It is claimed for salophen that whenever salicylic acid is indicated salophen should be tried in its stead, and for the reasons above stated. This, of course, implies that salophen would be of value in such diseases as acute articular, chronic, and muscular rheumatisms, neuralgia, cephalalgia, sciatica, gout, influenza, scarlatina, and in certain cutaneous diseases; and such proved to be the case.

Taking the rheumatic and gouty class of ailments first, the experience of American and Continental physicians points clearly to the great value of salophen in acute articular rheumatism. In a paper by Dr. Richy, of New York on "A Therapeutic Study of Salophen," published in the *Medical Examiner*, October, 1898, the evidence as to its action is conclusive. Dr. Richy quotes Dr. Guttman, Dr. Hirschmann, and Dr. Frohlich, both of the Imperial General Hospital of Vienna, Dr. Lutze, Dr. Lange, Dr. E. Koch, Dr. Hardenbergh, Dr. B. H. Waters, of New York, and many others. The experience of all of these are that salophen relieves such cases more rapidly than the salicylates. Dr. Richy says:—"From a study of the literature on salophen in acute articular rheumatism it appears that the drug, whilst endowed indeed with all the properties of the salicylate of sodium, is completely devoid of its unpleasant after effects." Dr. Richy also calls attention to the efficacy of salophen in scarlatina, observing that it presents many symptoms and complications similar to those of acute rheumatism; it seems, therefore, reasonable to use salophen at the beginning of an attack of scarlatina, with the effect that the congestion of the throat rapidly subsides. Such a line of treatment cannot fail to favourably modify the course of the worst cases of scarlatina.

Cases of tonsillitis appear to have been treated with marked success by salophen, especially when connected with a rheumatic diathesis.

The author's experience of salophen in rheumatoid sciatica has shown it to be of great value.

As regards cutaneous affections, Dr. Radcliffe Crocker, in the treatment of psoriasis, has substituted salophen for salicylate of soda, in consequence of the disturbance occasioned by the latter drug. Dr. E. Wannemaeker, of Ghent, is also in favour of salophen in most cases of skin affections accompanied by itching, such as prurigo, urticaria, psoriasis, pruritus, and seborrhoeal eczema.

In the concluding observations of Dr. Richy's paper the following occurs:—"I would mention that salophen has also been employed with success as an antiseptic in intestinal affections. Dr. Hare considers it preferable to salol in the treatment of cholera. Dr. Caspar regarded it of value in typhoid fever, while Dr. Cuillini and Dr. Viti, as a result of experiments on animals, have established the fact that salophen acts as an anti-fermentative in the intestinal canal. Although I have no personal experience as to its utility in this class of disease, the evidence adduced in its favour is sufficiently strong to render it worthy of a careful trial."

I believe, however, that it is in influenza that salophen is more especially valuable, and in my letter previously referred to this was the point that I particularly desired to emphasise. A further experience of its use in influenza during nearly a year has but tended to confirm, more strongly than ever, the views that I then held, and, as this disease is now rife all over the Kingdom, it may be opportune to recapitulate to some extent my opinion. I then said "It is however as a specific for influenza that I desire now to call attention, and from the evidence adduced, there can be little doubt that salophen stands pretty well at the top of the list of all the reputed specifics for the cure of that disease."

"Dr. Hennig, when speaking of influenza, says that among the remedies applied for neutralising neuralgic pain, none have proved so efficacious as salophen, and he 'recommends salophen most cordially in the nervous forms in which influenza presents itself.' Dr. Goldschlager, of the Wieden Infirmary, Vienna, reports that he obtained 'some extraordinarily favourable results in treating influenza with salophen.' Again, Dr. Drews, of Hamburg, is still more emphatic. He states that 'the effect of salophen on the nervous forms of influenza is so favourable as to cause me to declare it, unhesitatingly, to be a specific for the nervous forms of influenza.' This statement with regard to its specific action is fully endorsed by Dr. Claus, of Ghent, and other physicians. In the face of this unanimous testimony as to the value of salophen, coming from men whose *ipse dixit* is above suspicion and incontrovertible, it is clear that we are in possession of a remedy that will help us in checking the ravages of this recent scourge to society."

In support of the above, and to quote more recently, Dr. Richy states that Dr. A. Claus "assigns to it a leading place among specifics for influenza," that Dr. A. Hennig "found no remedy so constant in action in influenza as salophen." He further states that Dr. J. M. Thompson reports that "he had better results in *la grippe* from salophen than from any other remedy."

The extreme prevalence of influenza, at the present time, affords a favourable opportunity for testing the merits or otherwise of salophen in this disease, and of showing whether the deductions arrived at by the profession, on the Continent and America, as to the value of the drug are fallacious or whether it is capable of bearing that impartial trial that those who believe in it are anxious should be extended to it.

Clinical Records.

A COMPARATIVELY RARE INJURY TO THE DISTAL PHALANX OF THE FINGER. (a)

By JOHN EWENS, L.R.C.P. Lond., L.R.C.S. Ed.,

Consulting Surgeon Royal Hospital for Sick Children and Women, Bristol.

I HAVE purposely introduced the word "comparatively" into the title, as, although I have not been able to find any description of the accident in any work of surgery within my reach, it is quite possible that others may have met with it more frequently than myself.

I do not remember having met with more than three cases, the first occurring three years since to a middle-aged woman; the second to a youth about 15; and the third to an officer in Her Majesty's Army.

In each case the accident was produced by the finger suddenly impinging with great force upon a hard immovable substance, and the ungual phalanx was bent forward as in a dislocation, but the ease with which the displacement was remedied, and with which it returned to its abnormal position, proved that this could not be. The pain following the accident was severe, and, on seeing the patient within an hour or two, there was great tenderness, pain, and swelling situated over the proximal end of the phalanx and the joint, with great heat of the surface. The pain was speedily relieved in great measure

(a) Abstract of paper read before the British Orthopaedic Society, December 16th, 1899.

by putting the finger in a proper position on a well-padded splint, reaching to the wrist joint, and kept there by narrow strips of plaster and bandage. Any attempt to leave off the splint gave great pain, and if allowed, the phalanx would have at once returned to its abnormal condition.

In the first two cases, which were under my own supervision, the splint was not removed for a month, when everything was found to be right, except that in Case 1 pretty severe neuralgic occasional pain came on, when the finger was used. This gradually subsided under application of tincture of iodine.

Case No. 3 I did not see till 8 months after the accident (about eight weeks ago), when I was consulted by the patient as to whether any operation could be performed to restore the normal condition of the finger. I found the phalanx could not be extended by the action of the tendon, and it was flexed to an angle of 40 degs. Great pain was often felt, and there was some swelling of the parts. I did not recommend an operation, considering that the division of and shortening the extensor tendon would involve greater risk than was justified. I therefore recommended painting with iodine, and using the finger at his discretion. The practitioner who was consulted applied a splint; but left it off in four or five days, and ordered passive movement, and this alternate treatment of splinting and movement had been continued ever since. When last I saw the patient, about two weeks ago, pain had subsided, and the joint could move freely, but I doubt whether the proper shape of the finger can ever be restored.

Now what is the nature of the accident? Evidently not dislocation for the reasons above stated. Neither is it likely the tendon itself could have been ruptured in the ordinary way.

I would suggest that either (1) the flattened and alternated termination of the tendon may be torn through close to its insertion into the phalanx; or (2) more probably the periosteum may be raised from the bone, thereby causing effusion of blood, and subsequent periostitis, thus accounting for swelling and severe pain. In either case perfect rest and careful adaptation of the parts must be maintained for certainly four weeks, and it is probably due to the neglect of these precautions, the patient (No. 3) owes, what will doubtless be, a permanent deformity. As he is an officer, although the injury, being the little finger of his left hand, will not interfere with his duties, yet for appearance sake any operation considered justifiable would be readily consented to.

Transactions of Societies.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

MEETING HELD WEDNESDAY, JANUARY 17TH, 1900.

Mr. A. G. MILLER, President, in the Chair.

Dr. NORMAN WALKER showed a case of "acne varioliformis"; the condition was fairly typical, the scalp as well as the face being affected, thus differing from ordinary acne. Although the patient had improved under iodide there was no reason to suppose that the lesion was syphilitic.

Mr. MACGILLIVRAY showed a specimen from a case of fracture of the skull.

Dr. CHARLES BEGG read a paper on

CLINICAL EXPERIENCES WITH SALOL IN THE TREATMENT OF SMALL-POX.

His attention was first called to the action of this drug in subduing cutaneous irritability by observing a patient suffering from cystitis who was taking 15 gr. doses of salol three or four times a day. The man, a resident in China, was a martyr to mosquito bites; they usually caused such irritation as to lay him up completely, yet while taking salol (although he dispensed with mosquito curtains and was covered with bites) he remained comparatively immune from itching and dermatitis. Dr. Begg then began to use salol in various forms of irritable skin disease with decided benefit. He has employed it

in a number of cases of small-pox in China occurring both in Europeans and in unvaccinated natives. He found that it removed the irritation almost entirely, and prevented the scratching to which so many ill effects, such as sleeplessness, infection of the eyes, &c., were due. A most important consequence of treatment with salol was that the eruption did not pass beyond the vesicular stage—the vesicles did not mature. In an Englishman over 60 years old with severe confluent small-pox, who was treated with salol, only two groups of vesicles went on to suppuration. He recommended that salol be given in such cases in divided daily doses of one drachm, and had seen no bad results save a degree of mental depression. He ascribed the therapeutic action of the drug to the elimination by the skin of salicylic acid and phenol.

Dr. NORMAN WALKER concurred with the speaker as to the benefit given by salol and salophen in cases of irritable skin disease. Salol, rather than arsenic, was probably the most useful all-round drug in the possession of the dermatologist. The pitting in small-pox was largely caused by the pressure of scabs which were allowed to dry; if they were kept moist, so as not to contract, scarring would be greatly lessened. He asked whether Dr. Begg had any experience of the red light treatment of small-pox. Dr. Harvey Littlejohn also spoke, and Dr. Begg replied.

Mr. SHAW McLAREN read a paper on

PERMANENT DISLOCATION OF THE PATELLA.

Such cases were not common; the dislocation was usually to the outer side, the leg being everted and the anterior surface of the patella directed externally. As a rule the affection first attracted attention after a slight injury to the knee by a fall; it was rarely congenital. In examination of the records of previous cases he found that the following conditions had been said to be associated with dislocation:—1 knock-knee; 2. dislocation at birth; 3. synovitis; 4. defective development of the external condyle; 5. mal development of the patella; 6. permanent external rotation of the leg. In his case the patient was formerly the subject of rickets, and had well-marked genu valgum of the right leg. Both legs had been knock-kneed in childhood, but the left had spontaneously recovered. The right leg was permanently rotated outwards, and there was defective development of the external condyle of the femur, the patellar surface of the bone being narrow, the ridge on the external condyle absent, and the condyle itself abnormally rounded from side to side. He decided to operate, and did a preliminary osteotomy to connect the genu valgum. Thereafter he moored the patella by strong silk sutures to the aponeurosis of the vastus internus. The convalescence was very protracted owing to wasting of the rectus femoris and consequent loss of power, but in the end the patient got an absolutely useful limb, and now, four years after the operation, showed no trace of recurrence.

Dr. HARVEY LITTLEJOHN read a paper on a case of

MURDER AND SUICIDE BY CUT-THROAT.

The bodies of a man and a woman were found lying in an hotel bedroom. The woman was lying across the bed with her feet on the floor, dressed in her out-door clothes, with thick jacket and gloves on, only her hat having been removed; the man lay face downwards across her body. There was a single clean-cut wound in the throat of the woman extending from the symphysis menti to the angle of the lower jaw, the left internal jugular vein having been completely divided and the bodies of the vertebrae scored by the knife. In the man's throat there was a series of cuts extending from the left angle of the lower jaw to past the middle line. A blood-stained razor lay close to his right hand, which was also blood-stained. In such a case the possibilities were double murder, double suicide, and murder and suicide. The last-named alone accorded with the facts; the wound in the throat of the woman was single, a clean, deep cut, dividing part of the collar of the jacket; there was no blood about the room or on the front of the woman's dress or on her hands, and from this it appeared that she was probably thrown suddenly backwards while resting on the edge of the bed, and had been murdered before she had had time to cry out or struggle. The wound of the man's throat was evidently

self-inflicted, as shown by its direction and multiple character, as well as by the blood stains on his hands, and the position of the razor.

BRITISH GYNÆCOLOGICAL SOCIETY.

MEETING HELD JANUARY 11TH, 1900.

The President, Dr. MACNAUGHTON-JONES, in the Chair.

ANNUAL MEETING.

THE Treasurer, Dr. MANSELL-MOULLIN, having read his annual report, which was of a most gratifying nature, Mr. STANMORE BISHOP, of Manchester, moved its adoption, and a cordial vote of thanks to the treasurer for his services to the Society.

This having been unanimously adopted, Dr. HEYWOOD SMITH moved that a cordial vote of thanks be passed to the retiring officers for their great and untiring services. He referred especially to the President, Dr. Macnaughton-Jones, in whom the Society had shown its confidence by electing him a second year to fill the chair, and whom he characterised as a model President, courteous, hospitable, and most able in the discharge of his duties. He also specially mentioned the good work of the retiring secretary, Dr. G. E. Keith. The vote was seconded by Dr. DOLAN, of Halifax, and carried unanimously.

After the transaction of the business of the annual meeting, the retiring President, Dr. MACNAUGHTON-JONES, delivered his Valedictory Address on "The Correlation between Sexual Function, Insanity and Crime," which will be found in another column. He concluded his remarks with a brief review of the losses sustained by the Society during the past year.

Dr. C. H. F. ROUTH moved a hearty vote of thanks to the President for his valuable and interesting address. They had been regaled by a wonderful paper; but in view of the fact that this was the last address they would hear from Dr. Macnaughton-Jones, from the Presidential chair, he wanted to speak not so much about the paper, but rather of the man. He wished to thank him for the courtesy, hospitality and impartiality which had characterised his tenure of office, and for the learned and valuable contributions which he had made to their debates. Among the many distinguished past occupants of the chair, none had been worthier, or better fitted for the post. While many good qualities distinguished the natives of Great Britain, the true Irish gentleman was above all distinguished for the quality of heart, and Dr. Macnaughton-Jones exemplified in this respect the best traditions of his nationality. With regard to the paper itself, the subject thereof was of the greatest importance, and was one that was not often discussed. There was more insanity among women at the present time than formerly, and inasmuch as woman was the most civilising element in the community, it was a most important thing that they should study and practise all that was best in order to restore or maintain her health. Hence they were deeply indebted to Dr. Macnaughton-Jones for calling their attention to this subject.

Dr. W. J. SMYLY, Dublin, seconded the vote of thanks so eloquently proposed by Dr. Routh. The address to which they had listened was of the most deeply interesting nature, and was in itself an epitome of the opinions of the leading alienists and gynecologists on the subject. He wished also to echo the remarks of Dr. Routh on the brilliant Presidency which had come to an end that evening. He had himself been an original fellow of the Society, and could say that there had never been a time when the Society had passed through such a brilliant and successful phase as during the last two years. Eminent foreigners had been attracted to come and address them at their meetings; and the success had been largely due to the untiring activity of their President.

Mr. STANMORE BISHOP, in supporting the vote of thanks, remarked what a debt the Society, and especially the Provincial Fellows, owed to the President. There were many societies where a member felt that it did not matter to any one whether he was present or not; but

this was not the case with the British Gynæcological Society, every member felt at home, and this was largely due to the influence of the President.

The vote of thanks was carried by acclamation; and the President briefly acknowledged it.

The officers and council elected for 1900 are as follows:—

Hon. President: E. Barnes, M.D., F.R.C.P. (London). President: W. J. Smyly, M.D., F.R.C.S.I. (Dublin). Vice-Presidents: W. Armstrong, M.R.C.S. (Buxton), Clement Godson, M.D., M.R.C.P. (London), E. H. Hodgson, M.D. (London), F. Bowreman Jessett, F.R.C.S. (London), Skene Keith, M.B., F.R.C.S. (Ed. (London), Professor L. Laudau, M.D. (Berlin), J. Macpherson Lawrie, M.D. (Weymouth), J. J. Macan, M.D. (London), E. Milne Murray, M.D. (Edinburgh), James Oliver, M.A., M.D. (London), Professor A. Pinard, M.D. (Paris), E. D. Purefoy, M.D. (Dublin). Treasurer: J. A. Mansell-Moullin, M.D., M.A. (London). Council: W. Alexander, M.D., F.R.C.S. (Liverpool), W. H. Bourke, M.D. (London), Professor Murdoch Cameron, M.D. (Glasgow), John Campbell, M.A., M.D., F.R.C.S. (Belfast), G. Roe Carter, M.R.C.P.I. (London), John H. Dauber, M.B. (London), T. Eastes, M.D., F.R.C.S. (Folkestone), J. Furneaux Jordan, F.R.C.S. (Birmingham), George E. Keith, M.B. (London), H. Macnaughton-Jones, M.D., F.R.C.S. (London), T. Morton, M.D. (London), W. H. Newnham, M.B. (Clifton), J. Inglis Parsons, M.D., M.R.C.P. (London), Professor A. W. Mayo Robson, F.R.C.S. (Leeds), F. W. Ramsay, M.D. (Bournemouth), C. H. F. Routh, M.D. (London), F. F. Schacht, M.D., B.A. (London), Professor W. Japp Sinclair, M.D. (Manchester), W. Simon, M.D. (London), Heywood Smith, M.D. (London), R. T. Smith, M.D. (London), J. W. Taylor, F.R.C.S. (Birmingham), W. Travers, M.D., F.R.C.S. (London). Editors of the Journal: J. J. Macan, M.D. M.A. (London), Arthur E. Giles, M.D., B.Sc. (London), H. Macnaughton-Jones, Junr., M.B. (London). Hon. Secretaries: Arthur E. Giles, M.D., B.Sc. (London), Charles Ryall, F.R.C.S. (London). Trustees of the Property of the Society: G. Granville Bantock, M.D., Fancourt Barnes, M.D. F.R.S.E., Clement Godson, M.D., M.R.C.P.

France.

[FROM OUR OWN CORRESPONDENT.]

PARIS, January 20th, 1900.

AMAUIROSIS.

M. DANLOS presented a man at the last meeting of the Dermatological Society who had contracted syphilis some three years previously, and from repeated attacks of iritis had almost completely lost his sight. He was submitted to different forms of mercurial treatment in several hospitals, and at one place received thirty injections of bin-iodide of mercury. That extended treatment but slightly improved his condition. When the patient entered the speaker's ward he was suffering from a severe attack of mercurial stomatitis, which had to be treated immediately. At the end of three weeks, the speaker was able to inject calomel subcutaneously, and the effect of the calomel was most surprising. The sight improved rapidly, and at the end of the fourth injection he had recovered completely. M. Danlos said that he had communicated this case for the purpose of re-habilitating calomel, which had been strongly attacked as a treatment of syphilis these last years.

M. Fournier said that calomel was doubtless a remedy for syphilis; certain lesions of the tongue or of the larynx, certain cases of phagedænum improved and even got well as by enchantment under the influence of that drug. But in other cases calomel has been known to

fail where injections of soluble salts of mercury, or even simple pills of proto-iodide gave very good results. Further, as long as a means was not found of sparing the patient the terrible pain caused by injections of calomel, the remedy should be reserved for exceptional cases. Another member observed that the dose of calomel varied with the individual; where grave accidents happened, the intolerance was perhaps due to glycosuria.

INFANTILE ECLAMPSIA.

Eclamptic attacks in infants being due for the most part to gastro-intestinal intoxication, the evacuation of the digestive tract is of first importance. However, this means did not always succeed in preventing recurrent attacks of convulsions, and in such cases bromides with or without chloral were generally prescribed. Dr. Lange has found that phosphorus frequently used for rickets exercised a sedative action on children, superior to the bromides. He administers it in the same, that is to say in a solution of oil, during three or four days to obtain a definite cure of the convulsions.

PULMONARY CONSUMPTION.

Dr. Mendel has instituted a new kind of treatment for consumption and which has given him considerable satisfaction. By means of a long curved syringe of the capacity of a drachm he injects through the mouth into the trachea about three drachms of the following solution:—

Essence of eucalyptus	} aa 3j ;
Essence of thyme	
Essence of cinnamon	
Iodoform, xx grs. ;	
Bromoform, x drops ;	
Sterilised olive oil, ʒiij ss.	

The tracheal injection is practised daily. The patient who feels the solution trickling into his lungs experiences an agreeable sensation of warmth and does not cough. In his early experiments Dr. Mendel operated with a mirror, but now he is able to dispense with that aid. The patient holds his tongue himself outside his mouth between thumb and finger by means of a napkin. The treatment is simple and inoffensive, and the effects varied with the stage of the disease. In patients in the first stage he has succeeded, after two or three weeks' treatment in relieving the cough and expectoration, and even stopping them altogether, strength, sleep, and appetite had also returned. In the two remaining stages of the malady the results were not so satisfactory, but still considerable benefit was obtained, expectoration easier and less abundant, strength and appetite improved.

In explaining the action of the treatment Dr. Mendel says that the medicated oil injected into the orifice of the trachea descends slowly, bathing the walls. It thus penetrates the bronchial tubes, creating a large surface of evaporation at the point where the bronchial tubes branch out. Before the oil is absorbed the air entering the lungs is saturated with volatile odours that destroy the bacteria.

In certain cases where the tracheal injections could not be performed daily, he has substituted a medicated enema composed of a glass of milk with the yolk of egg and from ten drops to two teaspoonsful of the solution mentioned above. Excellent results have been obtained from this treatment.

Germany.

GELATINE AS A HÆMOSTATIC.

The *Deutsch. Med. Wochens.*, 49/99, reports a case of almost fatal epistaxis cured by injection of a solution of gelatine. A woman, æt. 68, bled so profusely and continuously in spite of all ordinary measures, that half a litre of physiological solution had to be injected subcutaneously. The following treatment was then carried out, syringing of the nasal cavity with warm saline solution, to get rid of crusts and blood clot, then twenty to thirty grammes of warm fluid gelatine were introduced into the nose by means of a glass syringe with a wide nozzle, the *alæ nasi* being pressed upon the nozzle in order to prevent the gelatine at once running out again. After removal of the syringe, the gelatine hardened quickly, and the bleeding was arrested at once.

In the same journal a series of successful instances of the use of gelatine as a hæmostatic is given by Dr. Bauermeister. He used the gelatine internally in a 10 per cent. solution in three cases of hæmorrhage from the gastro-intestinal canal, and also externally in the form of a tampon soaked in gelatine, in several cases of epistaxis (in one of which plugging had been unsuccessful), in one case of profuse bleeding from the uterus, and always with prompt and good result. In only one case a case of hæmorrhage from the lungs, twenty to thirty grammes of gelatine daily failed to arrest it. The writer believes that it undoubtedly facilitates coagulation, and that when applied on the surface it can do no harm. As to its subcutaneous employment, he acknowledges that not enough is as yet known of its possible danger to encourage one to make a trial.

THE ORIGIN OF OXALIC ACID IN URINE.

The *Deutsch. Med. Zeitung* (103/99) gives a brief summary of an article on the subject by Dr. Felix Lommel.

The conclusions were mostly arrived at as a result of a series of experiments by the author on himself.

1. Oxalic acid found in human urine depends but little, if at all, on oxalic acid introduced into the system with the food.
2. By far the greater part is formed in the system itself.
3. The oxalic acid found in urine after taking large quantities of oxalates in the food bears only a very small proportion to that introduced.
4. The excretion of oxalic acid does not stand in direct relationship to decomposition of albumen.
5. Food rich in nuclein, as well as the known uric acid increase, also considerably increased the oxalic acid.
6. Food rich in gelatine also increased the excretion of oxalic acid.

LUXATION OF CONGENITAL HIP DISLOCATION.

LORENZ is so convinced of the importance of his "bloodless operation" on the hip-joint for congenital dislocations, that he has taken the subject to the German

Surgical Congress for discussion. In cases of children born with the dislocation where the acetabulum becomes filled up, and the ligamentum teres absorbed after the course of years; in some cases, after the lapse of fifteen years, he has replaced the head of the femur over the accumulated deposit, and retained it in position till the pressure has produced a depression in the new growth and finally made a new acetabulum. He thinks the operation in unilateral luxation should not be undertaken by his method after ten years of age, while bilateral should not exceed the seventh or eighth year, and even with these ages great caution is necessary to prevent accidents incidental to the operation. The most severe of these accidents in his own practice was in the case of a girl, *æt.* 13, on whom he had operated, in whom gangrene of the leg ensued, from the head of the femur, getting entangled with the femoral artery in the reduction. He recorded ten cases where the head of the femur was fractured from the shaft, the patients' ages ranging from nine years to sixteen years, besides other fractures of the pubic and iliac bones. Twice he has had paralysis of the peronei muscles, and five times in the quadriceps. Out of 360 cases treated, he has had three die from chloroform, and twenty-two cases unaffected by the interference.

The patients above these ages he prefers Paci or Sen-ger's operations, as these affect the soft parts only, and offer a greater chance for a movable joint.

The frequency of the re-luxation forwards and upwards, has led Lorenz to take actinogrammes to show the relative height of the ligamentum teres, and the improbability of re-luxation backwards.

Petersen said that a form of reduction for congenital luxation had long been practised in Bonn, recommended by Schede, that could not be said to be a success as there was too much force applied. An apparatus had been devised to measure this force accurately, but with all this precision eight unilateral cases out of a total of 161 had been successful. In a very large number of the cases the head of the femur could not be retained over the site of the acetabulum when replaced owing to the absence of capsule and ligament while the cavity is filled up.

There are some cases with favourable conditions which admit of retention, and with slight inward rotation may be kept for a short time and finally retained, when an outward rotation may bring the bone again into its proper situation. During these periods of alteration a plaster of Paris binding is preferable.

Recently Schede has tried a forward twisting of the femur, and performed osteotomy under the trochanter. After three or four months' retention with a bandage in this inward rotated position the bandages are removed. The Röntgen rays are used while the head of the femur is turned to its normal position. While the child was under chloroform for osteotomy, a strong gold wire was passed through the trochanter into the neck of the femur with the ends protruding by which the upper part of the femur could be held in an inward rotated position after the plaster of Paris bandage was applied. After five weeks this wire or needle can be withdrawn, while the bandages may be removed three or four weeks later.

In the discussion that followed Mikulicz said that he had met with 100 such cases and found many of them easily replaced. He considered the luxation occurred in the

latter months of uterine life, probably many of them intra-partum. One of the principal hypothesis in the production of this displacement was the extraordinary development of the ligamentum teres which, by its interposition displaced the head of the femur. In many other cases we find an interposition of a capsule which seems to have grown in over the acetabulum, displacing the head of the femur outwards. He thought Lorenz's bloodless treatment the best method of managing these displacements, although some cases required more heroic operative measures. Heubner was in favour of Schede's treatment, combined with an extension apparatus. His experience led him to believe that 50 per cent. of such cases only required a corset or form of support for their correction, while 10 per cent. required operative treatment. He thought Lorenz's cases came under the former category.

The Operating Theatres.

CANCER HOSPITAL.

SUB-PERITONEAL HYSTERECTOMY.—MR. BOWREMAN JESSETT operated on a woman, *æt.* 30, who had been admitted suffering from large fibroids of the uterus. The tumour extended to about half an inch above the umbilicus, and laterally on the left filled up the iliac fossa of that side: *per vaginam* a large mass was discovered in Douglas's pouch pressing somewhat on the rectum, and causing some difficulty in defæcation. The uterine sound passed four and a half inches. The patient had extensive hæmorrhage, and her usual periods lasted from ten to twelve days; she was blanched from loss of blood. The whole tumour was fairly movable, and the woman suffered but little pain. Mr. Jessett made a long abdominal incision in the middle line, extending from the pubes and the umbilicus, and going about half an inch to the left side of the latter. The tumour with some difficulty was delivered and the broad ligaments ligatured on each side, clamps being applied on the uterine side to arrest any hæmorrhage; the bladder was found to extend very high up on the tumour; it was carefully peeled off and the anterior flap of peritoneum formed. Posteriorly the flap of peritoneum was dissected off and the uterine arteries were ligatured on each side. The cervix of the uterus was next cut through with scissors, leaving a wedge-shaped opening, and the tumour was removed. The wedge-shaped piece of the cervix was laced carefully together with catgut suture and the anterior and posterior peritoneal flaps were united with a very fine silk suture across the floor of the pelvis, care being taken to bury the stumps of the lateral ligaments which had been previously ligatured. The patient during the operation was in Trendelenburg's position. The parietes were closed by a single silkworm gut suture, care being taken to catch the different layers of integuments in the parietes with each suture. The patient bore the operation very well. Mr. Jessett remarked that it was often difficult to decide whether to recommend operation to women suffering from fibroids or not. He thought that in cases in which patients were losing large quantities of blood or in which pressure upon some important viscus or part caused great pain, or possibly pressure on the ureter produced hydro-nephrosis, operation should be recommended; in cases,

however, at or near the menopause, where the presence of the tumour caused no great trouble or inconvenience, then he considered the surgeon would not be justified in advising an operation, as doubtless a number of women go about with very little inconvenience, although burdened with fibroid tumours of moderate size, and, no doubt, after the menopause, the growths often decrease in size.

The subsequent progress of the case was most satisfactory.

PYLOROPLASTY AND CHOLECYSTOTOMY.—Mr. CHARLES RYALL operated on a woman, æt. 55, who had been admitted for constant sickness; she had suffered for a year from abdominal pain in the epigastrium and right hypochondrium which had never been paroxysmal in nature and never very severe. During the last six months she had suffered from sickness, which lately had increased in frequency and usually occurred after food; she had never had jaundice, and there was no history pointing to any previous attack of gastric ulcer. There had never been any blood in the vomit. The patient was greatly emaciated. On examination the stomach was found to be considerably distended, and there was tenderness in the right hypochondriac and epigastric regions, where an indefinite tumour, which was movable, could be distinguished. Malignant disease of the pylorus was diagnosed, and it was resolved to perform gastro-jejunostomy to relieve the sickness. On opening the abdomen by a median incision above the umbilicus, the pylorus was found to be the site of chronic fibroid thickening, causing stricture, and was not affected with malignant disease; the gall-bladder was found thickened and full of numerous calculi; it was therefore resolved first of all to perform pyloroplasty; this was done by dragging the pylorus out of the wound, shutting off the abdominal cavity with sponges, and making an incision in the long axis of the viscus, the wound was drawn apart and sewn up in the usual manner, the mucous edges being brought together by continuous suture, and the sero-muscular layers with a series of Halsted's sutures. The gall-bladder was next emptied through an incision below and parallel to the costal margin, and 256 calculi of various sizes were evacuated; the edges of the gall-bladder were stitched to the wound and drainage was resorted to. The median abdominal incision was then closed in three layers. Mr. Ryall drew attention to the condition of the pylorus, for it was often impossible, he said, to diagnose the condition he had found from malignant disease, as the pylorus may become so thickened as to form a definite tumour, the cause could not always be traced to an ulcer, but might possibly be, sometimes, the result of chronic dyspepsia. With regard to pyloroplasty the result, he said, was most satisfactory in cases of non-malignant stricture of the pylorus. The procedure was a very simple one, the object being to increase the calibre of the pylorus, this being done by making a longitudinal incision and converting it into a transverse one by drawing it apart in this position. He preferred this operation to gastro-jejunostomy, owing to its simplicity and lower mortality, and to Loreta's because after this latter the stricture so frequently recurs. As to the gall-bladder he pointed out that it was very strange the patient had never had an attack of biliary colic, as the thickening of the gall-bladder

and the surrounding adhesions pointed to a previous attack of cholecystitis. Although the pylorus was implicated in the adhesions; the gall-bladder, he pointed out, formed evidently the chief part of the tumour felt before operation. The gall-bladder was not closed, he remarked, after operation owing to the unhealthy condition of its walls, but was secured to the abdominal wound and drained.

The patient made an uninterrupted and very satisfactory recovery, all her symptoms being relieved, and the drainage wound gradually closing.

WEDNESDAY, JANUARY 24, 1900.

UNQUALIFIED MEDICAL PRACTICE IN 1900.

IN spite of generations of active protest on the part of the medical profession the hydra-headed beast of unqualified practice rears its hundred heads with undiminished vigour. In the present year of grace, however, our readers are still awaiting, as their fathers and their grandfathers have done before them, the Hercules that shall demolish the evil monster that thrives upon the life blood of the nation. Everywhere quackery is rampant. No corner of the United Kingdom, no portion of our colonies, is too remote a field for the activities of the vendor of patent medicines and other nostrums, and of the unqualified quack who undertakes to cure fractures, dislocations, ruptures, cancer, cataract, rheumatism, baldness, deafness, consumption, epilepsy, and, indeed, every ill that human flesh is heir to. On the other hand, we have a legislature that is either indifferent or actually favourable to the continuance of piratical medical practice. At the present moment there are members of Parliament with large interests as directors and shareholders in some of the most extensive of the patent medicine companies that flood the country with their deceptive literature. It is a well-known

fact that during the life of a late notorious bonesetter, any attempt to introduce legislation against that branch of quackery would have been fruitless, owing to his wide *clientele* among members of Parliament and the aristocracy. The present state of affairs is ludicrous. Only when a bogus practitioner is incautious enough to give physic to his customers, does he lay himself open to prosecution by a clause that exists under the Apothecaries' Act. Why penalties should not be attached to unqualified practice except under that condition is a standing scandal to the consistency of British law. In this country it has been very rightly determined that the interests of the public demand that every man who practises medicine and surgery must first pass through a definite curriculum, and then be duly certified by a recognised medical corporate body as possessing adequate professional knowledge. Then the legislature and the General Medical Council proceed to keep a tight hand upon men qualified under stringent conditions. Outside practice, however, the thing that damages the public and stultifies the precautions of legitimate qualification is allowed to sap the vitality and plunder the purses of Her Majesty's lieges at its own sweet will. When will a British Government deal with this important question with the thoroughness it deserves? No real advance can be looked for until the General Medical Council, which has the ear of the Cabinet, is radically altered in tone, temper and constitution. The increase of number of direct representatives becomes in this way an essential of prime importance. So, too, the indirect increase of popular representation that would result by the electoral return of the council members of colleges and universities now nominated by some small governing body in each corporate constituency. As often pointed out, a great deal may be done by a better use of the weapons already in our hands. The General Medical Council has done one thing that places the profession in a much stronger position when asking for legislation against unqualified practice, namely, the abolition of the unqualified assistant. That small and unsatisfactory contribution appears to be all that can be expected from that quarter, and medical men must trust to themselves and their own organisation if they want any real and efficient protection of their professional interests. One way in which indirect good may be done lies undoubtedly in the direction of the reform of death registration. Many a prescribing and visiting chemist, and quack practitioner would be considerably restrained by the fear of a coroner's inquiry in all cases of improperly certified or uncertified death. On the part of the public there is a pronounced dislike to any difficulty about a death certificate, and that in itself would be certain to tell in favour of legitimate medical practice. The policy of the Registrar-General of Births and Deaths in the United Kingdom has lately shown a promising activity, so that local registrars now refuse certificates of death that they would formerly have accepted from unqualified persons. It is greatly to be regretted that there are

not more medical men in Parliament, where they might both initiate and inform the legislature upon medical matters. Some day it is to be hoped that our chief organisations, notably the British Medical Association, will see their way to pay members of Parliament out of the funds contributed by the profession. It is only when the necessary infusion of the professional element has been brought about that we may hope for satisfactory results. In many countries of Europe, such as Germany and France, quack medicines and quack medical practice are not tolerated, and it is no small reproach to the intelligence of the British Empire that she has not yet recognised the necessity of ridding her subjects of such noxious pests. That the day of retribution and enlightenment will come sooner or later cannot be doubted, and meanwhile the rank and file of the medical profession may be counselled to sink petty jealousies and to join every professional organisation that offers any hope of achieving some success, however trifling, in the long and arduous campaign against unqualified practice.

THE CO-RELATION BETWEEN SEXUAL FUNCTION, INSANITY AND CRIME.

THERE is perhaps no branch of medicine that has more points of contact with the law than gynaecology, and it may be added that there are few departments of medical jurisprudence where these points of contact are more enveloped in obscurity and uncertainty. The relation of insanity to disease of the pelvic organs; so-called criminal acts which may be the resultant of these two factors; questions of unchastity and venereal disease as they arise in the divorce courts; criminal assault; artificial abortion in all its aspects, including wounds in the uterus and evidences of past or present pregnancy; the duration of pregnancy; these are some of the questions on which important legal issues may hang; and upon which, unfortunately, knowledge is by no means precise. The co-relation of sexual function with insanity and crime was the theme chosen by Dr. Macnoughton-Jones for his Valedictory Address before the British Gynaecological Society. He first discusses the influence of the menstrual function on a woman's character; but here he rather raises questions than lays down doctrines. Alienists, of course, recognise the ætiological importance of puberty and of the menopause in relation to some forms of insanity; and between the establishment and the cessation of the function, the occurrence of menstruation may be associated with mental disturbances. It may, however, be stated categorically that menstruation is not a disturbing factor, except in women otherwise predisposed to derangements of the mind. In a healthy woman it may induce a certain degree of irritability and depression of spirits, but nothing more; it is in the mentally unsound that it may be associated with sudden maniacal outbursts or pronounced melancholia. The same line of thought may be adopted when discussing the relation of pelvic disease to insanity. It

is more than doubtful whether any pathological condition of the uterus or ovaries could lead to insanity, except as the immediately exciting cause in a woman already predisposed thereto. The numerous cases recorded in which the cure of pelvic troubles, by operation or otherwise, has been followed by mental improvement in no way invalidate this view; for they are most readily explained on the supposition that the restoration to a sound condition of mind was hindered by the pelvic disorder, as it would have been by disease elsewhere. It may, however, be granted that diseases of the sexual organs probably exert a more profound influence than disease in other parts of the body. We gather that Dr. Macnaughton-Jones had proposed to dwell on some of the other medico-legal points that we have enumerated, had time allowed; and we can only regret that time proved in this case an *edax rerum*, for we would gladly have heard some pronouncements on these topics from such a recognised authority. Meanwhile, more facts are badly wanted, and we should like to see instituted, under the ægis of some learned society, a commission composed of leading gynaecologists, expert pathologists, and recognised legal authorities, to investigate and report upon some of the medico-legal aspects of gynaecology. Such an investigation, thoroughly carried out, would prove of the greatest value both in medicine and in law, and would facilitate the solution of many questions affecting a large section of the community.

THE APPEAL OF THE GOVERNMENT FOR HOSPITAL ACCOMMODATION.

WHATEVER the shortcomings of the Government have been so far, we must commend them for the steps which they are taking to make ample provision for the treatment of the wounded soldiers during and after the war. It is well known that the hospital accommodation in South Africa is limited, and that there is no room for the treatment of soldiers whose wounds have clearly incapacitated them for further service. Hence the wise decision has been arrived at to draft all such soldiers back to this country as soon as they have recovered sufficiently to enable them to bear the passage. Perhaps in the interests of the wounded men it would be better to allow them to complete their convalescence in the Colony, having regard to the splendid climate which prevails there, in comparison with the exceedingly unfavourable climatic conditions to which they have to submit after landing on these shores. But however expedient it might otherwise be to keep the severely wounded men in South Africa, the plan is impossible for many reasons. The scheme of the Government at present is, after the usual Service hospitals are full, to take up beds for Service purposes at various hospitals which can undertake to provide them. Already, several hospitals in London have arranged to place a certain number of their beds at the disposal of the Government, some without requiring payment, and others in return for out-of-pocket expenses. It is understood that the beds so

allotted will be under military supervision, while all the necessary treatment and nursing will be provided by the hospital authorities. The progress of the war has already clearly demonstrated that a very large number of wounded men will find their way to this country, and will have to be provided for, and in thus being beforehand in their arrangements in this regard the Government are to be congratulated. Meanwhile, we regret to see that a serious charge has been brought against the management of the military hospital at Woolwich. A correspondent has asserted that all the experienced orderlies having been sent to South Africa the wards are practically in charge of inexperienced youths, who are quite incompetent to discharge the duties of attending to the large number of cases of typhoid fever which are now under treatment. The charge is further accentuated by the statement to the effect that the cases are "terribly neglected." We trust that if the state of affairs is really that which this correspondent describes, the Government will lose no time in making good the defect in management, or allow the sick men to be drafted at once into a civil hospital where every necessary medical and surgical provision will be made for them.

Notes on Current Topics.

Difficulties of Diagnosis.

THE difficulties of diagnosis which present themselves to the general practitioner are not always of a technical nature. It has often been stated that errors in medicine occur far more frequently from want of care than from want of knowledge, but there are, so-to-speak, mechanical difficulties in the way of careful examination which sadly hamper the practitioner, while they press but lightly upon the hospital physician. First of all, the average practitioner has to cram many more visits into his day's work than the consultant, and he has consequently less time at his disposal to devote to the individual case. Then there is the indisposition of the lower-class patient to submit to a really thorough exploration, particularly in affections of the pelvic viscera. The hospital physician finds his patient in bed, or can insist upon adequate removal of garments, so that there is no obstacle to his examination, but similar inquisitiveness on the part of the outside practitioner would be regarded as a needless indignity. The consultant has every facility for making analyses of excretions and secretions, &c., of searching for bacilli on the spot which the practitioner can only have done at great expense of time and trouble and even money. Lastly, the hospital physician is not hindered by the sight of parasites which, in the dwellings and on the persons of the poor, exert a very great disinclination on the part of the medical man to too prolonged and too close a contact with his patient. Theoretically, of course, none of these considerations should be allowed to weigh when the accuracy of the diagnosis is concerned, but in practice they constitute genuine, if not insurmountable, obstacles to careful work.

We urge these considerations not so much to excuse errors of omission as of the nature of mitigating circumstances which the consultant may well bear in mind when passing judgment on his handicapped and erring brother outside.

Recent Mortality Statistics of Hysterectomy.

It is but a few short years since that hysterectomy, except perhaps for cancer of the uterus, was considered by surgeons to be far too dangerous an operation for general application. Even now the text-books continue to propagate the view that uterine fibroids are things which will probably cease to trouble the sufferer after the menopause. We know that this bloodless termination is far from being the rule; indeed, the presence of a fibroid or fibroids will often indefinitely postpone the functional change. Nevertheless, in view of the risks which the operation entailed before its *technique* reached its present standard of perfection, the counsel to adopt a purely expectant treatment was usually followed. The modern abdominal surgeon, however, has changed all that. He has reduced the average mortality of the operation to something like two per cent., and in some hands to an even smaller proportion, so that it ranks as a less dangerous operation even than ovariectomy. These achievements are not confined to any particular method or procedure, for what one surgeon succeeds in doing through the abdomen another arrives at through the vagina. The latter procedure, however, is obviously unsuited for the removal of the uterus when associated with large growths. Under these circumstances surgeons are justified in claiming that many women who might with propriety have been regarded as unsuited for this particular operation some years ago may now with confidence be recommended to seek permanent relief by the removal of the source of their troubles.

Myopia and Military Service.

A CORRESPONDENT complains in a morning paper that he, while a good shot, rider, and in other ways fitted for service at the front has been rejected on account of his short sight. Yet he states that with glasses he can "see as far as any one, and can sight a rifle as truly as the best." All this may be quite true, but still his shortness of vision may be beyond that permitted by the army regulations. It may here be pointed out that the regulations lay down that a candidate must with each eye separately, without glasses, read at least $\frac{3}{32}$. If he can read $\frac{3}{32}$ with either eye he may be passed as fit if with correcting glasses he can read $\frac{1}{2}$ with one eye, and at least $\frac{1}{4}$ with the other eye, provided that at the same time he can read J 4. with one or both eyes, without glasses, at any distance he likes. Thus if any volunteer fails to come up to this standard, not we think a very exacting one, when it remembered that in the Navy a candidate must be emmetropic, it is evident that he has not much to complain of if he be rejected for

faulty vision. Moreover, in these days of long distance engagements with the enemy, there is no doubt that a premium will ultimately be placed on perfect powers of vision.

The Registered, but Unqualified Dentist.

THE practitioner of dentistry who obtained admission to the Dentists' Register by reason of his having been in practice before the passage of the Act is a thorn in the side of those who have at heart to raise the status of dentists as a class. Never having entered into an engagement to abandon his liberty of action in the matter of advertising, he is enabled to compete with his diplomated rival on highly advantageous conditions without let or hindrance. One by one these more or less irregular practitioners will drop out, and not until they have disappeared will dental practitioners attain professional rank, though even then it will be necessary to provide against the intangible limited company. In the meantime, we are pleased to see that the Royal College of Surgeons of England are taking steps to check the levity with which certain registered but unqualified dentists make use of titular letters which are calculated to mislead the public into the belief that they possess dental diplomas. Now that the attention of the General Medical Council has been called to the existence of this abuse we do not suppose much difficulty will be experienced in securing a declaration to the effect that it constitutes infamous conduct in a professional respect.

The State of New York and the Prevention of Tuberculosis.

THE State of New York has been considering the advisability of establishing State hospitals for the treatment of tuberculosis. The scheme proposed recommends that every locality able to provide a hospital for consumptives should do so, and that the State should erect and maintain one or more hospitals in districts which are unable to maintain local hospitals. As we have pointed out on previous occasions, the best way for dealing with this matter in this country would be by the organisation of municipal sanatoria. The trend of opinion is certainly towards making some such provision for those afflicted with consumption, and perhaps in the course of a few years that which at present is regarded as expedient will be looked upon as indispensable in this connection. We are still far from insisting, to the extent that continental nations do, upon the contagious nature of tuberculosis, but there is no doubt that in the interests of the public health it would be better were some system of isolation to be resorted to for the treatment of persons suffering from pulmonary phthisis. For example to have consumption hospitals in the midst of a crowded population, instead of in the open country, where the tubercle bacilli would have much less opportunity of doing harm, must be indisputably inexpedient. The more crowded the community into which the tubercle bacillus makes its way, the more virulent are its destructive effects likely to prove. Viewed then from

this aspect, it is quite likely that each of the hospitals into which phthisical patients are taken for treatment in, say, London, become a fertile focus of the disease, and are largely instrumental in its dissemination. If, however, provision were made, by means of municipal sanatoria, to treat all the phthisical poor in towns far away from the centres of population, we believe that a material reduction in the amount of dissemination of tuberculosis would be the result.

The War and the Sale of Drugs.

THE Government a short time ago issued a warning regarding the sale of gas products to foreigners, and since then a Royal proclamation has been gazetted prohibiting the exportation of picric acid, trinitro cresol, carbolic acid, and cresylic acid. The object of these orders is to prevent the enemies of the nation from obtaining supplies of products used in the manufacture of explosive compounds as lyddite. But it is curious to note, as pointed out by the *British and Colonial Druggist*, that in consequence of this action by our Government, a counter-prohibition has been issued on the Continent. That is to say, foreign makers have ceased to offer for sale in this country salicylate and salol preparations. "This," the trade journal in question observes, "might be looked upon merely as a natural result of the stoppage of crude material; but the articles that are being held back by Government instruction on the Continent are chiefly used for explosive material, and so the British Government may possibly find itself worse off by the move that it has made than if it had left the matter alone." The position of affairs in this regard is not without interest, but at the same time more or less disturbance of trade is already taking place owing to the inclusion of carbolic acid in the prohibition order. The effect of the order is to prevent, of course, the exportation of this drug for medicinal purposes, and thus Continental and other surgeons who rely upon carbolic acid as an antiseptic will apparently for the present have to resort to some other preparation for the purpose.

A Medical Strike.

It is not often that we hear of medical men striking *en masse*, but this extreme course was last week decided upon by the physicians attached to a charitable dispensary in one of the outlying districts of Paris. Unfortunately one is not in a position to discuss the merits of the case because the reasons alleged by the medical staff for their action do not in any way tally with those of the governing body. According to the former the reason is that they object to a recent ordonnance compelling them to confine their ministrations to children attending the municipal schools to the exclusion of those receiving their education in a denominational establishment. The governors on the other hand assert that the real reason is that the doctors disapprove of the appointment of a particular physician to be the head of the staff, the physicians, as a body, claiming

indeed, that their chief should be selected by themselves, a not unreasonable contention if seniority is not to be taken into account. However that may be, the usual appeal to outsiders to fill the vacancies has been made, and it is confidently asserted that no difficulty will be experienced in carrying on the work of the institution. The most regrettable feature of the quarrel is that the real victims are the unfortunate sufferers, who are thereby deprived for the time being of the care which they require.

The Royal College of Surgeons of England and Medical Aid Societies.

THE resolution passed at the last annual meeting of the Fellows and Members of the College condemning the connection of fellows and members with friendly societies and other institutions which advertise or canvass for patients has been endorsed by the Council of the College, so that in future one important section of the medical fraternity, at any rate, will be unable to complain that they lack guidance in this matter. Doubtless other licensing bodies will follow suit, and the hands of the General Medical Council will thereby be greatly strengthened in dealing with offenders. No unprejudiced person will hesitate for an instant to approve of the action of the College Council which will go far to reform a practice which had grown into a great abuse. It remains to be seen how the ordinance will work in practice. The resolution applies as well to registered friendly societies as to other medical aid institutions, and it is difficult to see how such societies can be carried on without a certain amount of canvassing. It may be supposed that the term canvassing will only be held to apply to the employment of professional canvassers, as distinguished from propaganda by individual members, in other words against collective, as distinct from individual, efforts to recruit. While we are strongly in favour of the movement, which has for object the suppression of this particular form of unfair professional competition some allowance must be made for the conditions under which these societies exist, and that proviso might well be that no profit should be made by the society or institution out of its medical department.

The Representation of the University of London.

WE welcome the announcement that Sir Michael Foster has consented to become a candidate for the vacant parliamentary seat for the University of London. If the expediency of this one-sided representation be conceded it is obvious that the selection ought to be made on intellectual, and not on political lines, indeed any derogation in this respect would infallibly open the door to hostile criticism of the system under which universities are allowed a special member all to themselves. The scientific status of Sir Michael Foster, tardily recognised by titular distinction, is such that in all probability no dissentient voice will be heard now that he has come forward so that a contest may become unnecessary. His eminence in the scientific

world needs no comment or illustration, and at this critical period it is in the highest degree desirable that the university should be represented by someone thoroughly imbued with the academical spirit, who is at the same time in touch with modern educational requirements. The views of Sir John Lubbock, the late member, by no means commanded universal assent, and although it is stated that Sir Michael Foster is substantially in agreement with those views, we know enough of him to be sure that he will decline to commit himself to any line of conduct which would hamper the future development of the new university now in progress of organisation. We wish Sir Michael every success in his electoral campaign.

The Profession and the Electric Light.

THE inhabitants of Cavendish Square, Harley Street, and the adjoining thoroughfares, which have become the great centre of medical life in the metropolis, have for years displayed a curious apathy in all that concerns local government. With little spare time at their disposal and vastly unwilling to compete with the baker and the tailor for places on the vestry they have had to put up with government by proxy, using such influence as they possess with their tradesmen to prevent their district becoming a veritable slough of despond. Now, however, the worm has turned in consequence of the utter *sans gêne* of the Metropolitan Electric Light Company which has displayed a proclivity to cut off the light, with or without notice, to the immense inconvenience of its customers. It cannot truthfully be said that the President of the Local Government Board, after listening to the recent deputation, held out much hope of effectual interference, indeed, the only remedy he seemed to have in view was competition. The next step ought to be a combined action in the law courts, for although the amount of damages any individual can recover is ridiculously small, the inconvenience to the company of such a method of warfare could not fail to be very great.

Total Abstinence from the Business Aspect.

A CONTRIBUTOR to the *Lancet* presents the temperance question in a very original form which, indeed, is a refreshing departure from the habit of the every day apostle of that cult. He addresses his argument specially to the medical profession, and it, for the sake of brevity, may be put in syllogistic form as follows:—1. Every working-class family in England on an average spends six shillings a week on liquor, and actually much more if deduction from the total of families is made for those who do not drink. 2. If they did not spend this money they would have more to give the doctor and would not be inclined to sponge on the hospital when sick. 3. *Ergo*, the doctor ought, in his own interest, to persuade all the working classes to be teetotallars. Q.E.D. We trust the doctor will do so, but not for this sordid reason, and we may add that as long as the hospital system is as lax as it is, the mean, selfish, working man would resort to the hospital even if his pockets were full of bank notes.

Lyddite.

LYDDITE, the new explosive is so called from the little village of Lydd, situated near Dungeness, in the south east corner of Kent, where it is manufactured. It is produced by the action of nitric acid on crystallised phenol, or to a mixture of phenol and sulphuric acid. On cooling a crystalline mass is obtained: Picric acid ($C_6H_3(NO_2)_3OH$): $C_6H_3O + 3HNO_3 = C_6H_3(NO_2)_3OH + 3H_2O$. Picric acid is easily soluble in hot but only slightly in cold water. It is also soluble in alcohol and ether. Its taste, as its name implies (*πικρός*), is intensely bitter, and its tinctorial power is very great. The explosive properties of the picrates were discovered accidentally. About two years ago a fire, occurring in a chemical factory near Manchester, burnt to ashes some carboys containing picric acid; the acid melted by the heat flowed on a quantity of litharge, thus causing a violent explosion. To form the explosive, melted picric acid is poured into the metal shell and allowed to cool. The detonating charge consists of a picrate of lead or ammonium. The explosive power is said to be fifty times greater than gunpowder.

The Anti-Vaccinationists and the War.

THE anti-vaccination party are waxing wroth with the authorities because volunteers, who present themselves for service in South Africa, are rejected if they cannot produce evidence of successful vaccination. The anti-vaccinationists pretend that they cannot understand what such an objection can have to do with fighting the rebel Boers. We need not undertake to enlighten them upon this point. Perhaps, however, it would be worth while in this connection to suggest to the anti-vaccination party that they should consult the records showing the number of French soldiers who died from small-pox during the Franco-Prussian war, in consequence of the neglect of vaccination.

Longevity in the Profession.

THE recent death of Sir James Paget at the age of eighty-five, recalls that many distinguished members of the profession have, at different periods, attained to a great age. Moreover, at the present moment two such physicians are still with us, one of whom is eighty-four, and the other eighty-three, while one surgeon is seventy-nine. All this goes to prove that robustness, and sound physical attributes have a great deal to do with success in life, perhaps, as much as that mental power, commonly described as "brains." In the great majority of instances, the most distinguished men of the world have been those whose mental and physical capacities have been equally great.

A Peculiar Assault.

IN the days of our youth it used to be thought a huge joke to watch the effects on the epidermis of the selected victim of the hairs of *miruna pruriens*, better known by the name cowhage, or cow-itch, as it is popularly called. The irritation to which it gives rise is "colossal," to use a German adjective,

and it may under certain circumstances determine a dermatitis of serious import. A young man hailing from the neighbourhood of Devonport resuscitated this form of practical joke on the person of a publican's wife, but he has since had reason to regret the fact, inasmuch as he has been mulcted in the sum of £10 *pour encourager les autres*.

Housing of the Poor.

A RECENT report upon the above subject by Dr. Priestley, Medical Officer of Health for Lambeth, has gone the round of the newspapers, and attracted a good deal of attention in official circles. His contention is that the Housing of the Working Classes Act would be better administered under Part II., which enables the authorities to deal with single houses, than by Part I., which deals with unhealthy areas. Broadly speaking, there is something to be said in favour of his view, inasmuch as the cost of proceedings under Part I. falls on the landlord, while under Part II. the burden is thrown upon the ratepayers. Beyond that Dr. Priestley's views appear to be fallacious. Part I. empowers an authority to abolish a whole area of undesirable dwellings, packed together under bad conditions of outside light and air, bordering on narrow streets, and placed perhaps back to back. Now although such an area might as a whole be most detrimental to the welfare of the surrounding district, yet it might be at the same time impossible on technical grounds to shut up any single one of its contributory dwellings. It is to be hoped, therefore, that those journals that have given publicity to Dr. Priestley's views will take prompt steps to publish the other side of the question. In many ways the housing of the poor, especially in our great centres of population, is one of the most urgent problems of the day. It would be a thousand pities to allow distorted readings of a beneficent although admittedly imperfect Act to be circulated as maxims of light and leading from an accredited source. There are already sufficient stumbling blocks in the way of those who are desirous of raising the general standard of environment of the working classes, without any further darkening of counsel from official quarters.

Sleeplessness.

THERE is no more distressing complaint than sleeplessness a nemesis that visits the coach of all alike from prince to peasant. That it comes to avenge some abuse of the brain appears to be abundantly clear. The labourer who lives in the open and works hard sleeps soundly as the proverbial top, unless he becomes the subject of some chronic bodily or mental disease that robs him of his slumbers. To a certain extent a similar observation holds good as to the artisan class in towns. The average citizen, however, who lives in the busy rush of latter day commercial or professional life, as a rule suffers from more or less pronounced insomnia, apart from disease of the kidneys, or other organs. In some cases the want of sleep may be readily traced to

abuse of alcohol, tobacco, tea or other nerve poisons. Want of exercise is a common factor that leads to want of sleep, for which a sensible doctor will be wise in prescribing golf, bicycles, or other exercises with early hours and plain living. Nowadays worry is beyond a doubt one of the chief causes of wakefulness, and anyone who can lessen the stress and storm of modern life will discover the best and safest soporific. Yet few of us would desert any express trains for the stage-coach of our grandfathers. What we want is to adjust our lives to the altered conditions of the twentieth century. No candid and scientific physician would use drugs in the treatment of sleeplessness, except to tide over an emergency. Change of air, change of scene, change of occupation, early hours, plenty of exercise, plain living, are some of the best remedies. Sometimes a Turkish bath and a low pillow will mend matters.

The Surgeoncy of the City of Dublin Hospital.

ON Friday last the Board of Governors of this hospital proceeded to select one from the three names recommended to them by the Medical Board for the surgeoncy of the hospital vacated by the death of the late Mr. Wheeler. As we have reported, these names were those of Mr. Harry Croly, M.B. and M.Ch. Univ. Dub., and formerly house surgeon to the hospital; Mr. Henry Moore, surgeon to Mercer's Hospital, and also an ex-house surgeon to the hospital; and Dr. Lane Joynt, assistant physician in the Meath Hospital. When the governors met a letter was read from Mr. Harry Croly withdrawing his candidature on the ground that he did not desire to contest the position with Mr. Moore, and thereupon Mr. Moore was unanimously chosen to succeed Mr. Wheeler. We understand that Mr. Harry Croly has since offered himself for the surgeoncy of Mercer's Hospital vacated by the transference of Mr. Moore, and his valuable experience as house surgeon to a very active hospital ought to give him a recognisable claim.

Civil Surgeons at the Front.

THE medical profession has not only shared the deep wave of emotion that is sweeping over the British nation, but has been able also to contribute its quota of active help. The latest additions to the list have been made in the persons of Mr. William Turner, F.R.C.S., Assistant Surgeon to the Westminster Hospital, and Mr. Reginald Johnson, F.R.C.S., of University College Hospital. It is understood that Mr. Turner will be appointed to the Base Hospital of the Imperial Yeomanry, and will sail on the 27th. In addition to the foregoing, the London hospitals are at present represented in South Africa by the following distinguished surgeons. St. Thomas' by Sir William McCormac and Mr. Makins; the London by Mr. Treves; King's College by Mr. Watson Cheyne and Mr. Cheadle; Guy's by Mr. Fripp; St. Bartholomew's by Mr. Anthony Bowlby and Mr. Tooth. For the present nothing more need be said than that the

heartly sympathy and confidence of the profession are freely extended to this gallant little band of men chosen from the flower of Metropolitan surgery to succour the brave soldiers who are fighting our battles in South Africa.

Revision Classes at Westminster Hospital.

SPECIAL "revision" classes for the furbishing up of candidates for university and similar examinations are now held three times a week in connection with the Westminster Medical School. The plan adopted is to take a selected subject in pathology, which is duly discussed, and the points raised are subsequently illustrated by practical microscopical work. The course commences on the 30th inst. Time was when students belonging to one or other of the smaller medical schools were compelled to turn from their *alma mater* so soon as they aimed at anything above a mere qualification to practice. That time, however, is no more, and there are signs on the contrary that the smaller schools, with their proportionally larger proportion of clinical material are attracting the senior men from the more crowded centres of medical teaching to their special classes.

The Combatant "Non-Combatant."

THE *Cape Times* of the 14th of December, pays a high compliment to the conspicuous gallantry of Mr. Delap, a Surgeon attached to the G battery of Artillery, now with Lord Methuen. He was in the action in which the Marquis of Winchester was killed, and was noted for his courageous determination when attending the wounded on that occasion. Mr. Delap is a Licentiate of the Dublin Colleges, and son of the Rector of Valentia, co. Kerry.

PERSONAL.

MR. EDGAR A. BROWNE, F.R.C.S.Edin., has been elected President of the Liverpool Medical Institution.

THE Marquis of Zetland has given his house, Herse House, Falkirk, for the sick and wounded from South Africa.

MR. ALFRED COOPER, F.R.C.S., will open the discussion on syphilis at the meeting of the West London Medico-Chirurgical Society next month.

MISS JANE GILMOUR COX has been appointed junior assistant Medical Officer of the Lincolnshire Lunatic Asylum.

MR. WILLIAM ANDERSON, F.R.C.S., has been elected a member of the Board of Examiners of the Royal College of Surgeons of England.

MR. C. N. MACNAMARA, F.R.C.S., has been selected to deliver the Hunterian Oration at the Royal College of Surgeons in 1901.

SIR JOHN WILLIAMS, M.D., F.R.C.P.Lond., has been placed on the Commission of the Peace for his native county, Carmarthen.

MR. ARTHUR CHANCE, F.R.C.S.I., has been elected a member of council of the Royal College of Surgeons, Ireland.

DR. H. FRANKLIN PARSONS has been appointed Assistant Medical Officer Local Government Board and Medical Inspector for General Sanitary Purposes. Dr. R. Bruce Low has also been made an Assistant Medical Officer.

MR. ALFRED FRIPP, F.R.C.S., Surgeon-in-Ordinary to H.R.H. the Prince of Wales, assistant surgeon to Guy's Hospital, is named for the post of surgeon in charge of the proposed Yeomanry hospital.

MR. WM. HY. POWER, whom we mentioned a month ago as the likely successor of Sir R. Thorne-Thorne in the Principal Medical Officership to the Local Government Board, has now been appointed to that important post.

MR. J. N. C. DAVIES-COLLEY, having resigned the post of examiner in surgery at the Royal College of Surgeons, England, the Council will proceed to the election of his successor on February 8th. Notice to Fellows will be found in another column.

THE vacancy in the Committee of Management which conducts the conjoint examinations for the Dublin Colleges, created by the departure of Sir William Stokes for Africa, has been filled by the Council of the College of Surgeons by appointing Mr. F. R. Heuston, surgeon to the Adelaide Hospital.

DR. GEORGE BURBIDGE WHITE, F.R.C.S.I., sometime pathologist to the Meath Hospital and demonstrator in the Royal College of Surgeons of Ireland, announces his candidature for the surgeoncy of the Mercer's Hospital, Dublin, vacated by the transference of Mr. Henry Moore to the surgeoncy of the City of Dublin Hospital.

THE field hospital provided by the munificence of Lord Ivegh will leave Southampton early in the second week in February, its departure having been somewhat delayed for want of transport. Sir William Thomson, who is in chief medical charge, will leave by the ordinary mail steamer on February 3rd so as to have final arrangements made for the arrival of the expedition which will leave by transport a few days afterwards. We have already given the details of the organisation and the names of the medical officers in charge.

WE understand that the Royal College of Physicians of Ireland has called the attention of the Council of the College of Surgeons to the fact that it has felt itself called upon to require Mr. James Charles MacWalter, of Dublin, one of its Licentiates, to surrender his diploma for having resorted to methods of obtaining practice which that College regards as inconsistent with his pledge given when it was granted to him. Mr. MacWalter is known to be actively employed in managing one or more of the seven druggists' shops which

trade in Dublin under the title of Leonard and Co., and he was also the promoter of the abortive Company which started under the title of "Blaud and Co.," to carry on the business of physician, surgeon, and midwifery practitioner, as a limited company. On reference to the *Medical Register* we find that this gentleman held, until his resignation of the physician's Diploma, three qualifications, viz., the Diplomas of that College, and of the College of Surgeons, and also the Licence of the Apothecaries' Hall. Having now ceased to hold the first-named qualification, he retains two, and, therefore, remains on the *Register*, but if he should lose another Diploma, the question will remain as to whether the General Medical Council can leave his name on the official record in respect of one Diploma. We understand that the Council of the College of Surgeons has remitted to a committee to investigate and advise upon the matter.

THE DUBLIN HOLOCAUST.

THE Lord Lieutenant has ordered a departmental inquiry into the causes of the excessive death rate of the City of Dublin. The Commission is to consist of a representative of each of the following bodies, viz., The Irish Local Government Board (probably the Medical Commissioner, Dr. Stafford); the English Local Government Board (possibly Mr. T. W. Russell, M.P.), the Corporation of the City (representative not yet selected); the Royal College of Physicians (Dr. J. W. Moore, President); the Royal College of Surgeons (Dr. R. L. Swan, President); Sir Charles Cameron, Superintendent Medical Officer of Health for the City will, of course, be active in assisting the deliberations of the Commission. Meanwhile the health condition of the City is by no means improving. The Registrar General reports, on the 13th inst., a death-rate of 49.4 per 1,000 of the population, with a considerable increase in the zymotic mortality.

MEDICAL SOCIETY OF LONDON.

At the meeting of this society, which took place on Monday evening last, Mr. C. B. Lockwood read a paper on "The Pathology and Treatment of Appendicitis," which was illustrated by numerous lantern photographs of the appearances described by him. He discussed the alleged cure which was stated to have taken place in these cases under medical treatment observing that subsidence did not imply cure. By the aid of photographs of sections the author showed that the infection spread to the peritoneum through the lymphatics, the spread being favoured by the anatomical arrangement of the tissues. He described the different varieties of the disease ranging from mere appendicular colic to catarrh, stenosis, and finally gangrene and ulceration, remarking that the conditions appeared to be opposed to any natural process of cure.

Dr. Allchin contrasted the trend of current opinion in favour of the surgical treatment of appendicitis with the days when one's knowledge of this particular affection might be described as exceedingly vague and largely incorrect, and the treatment as an attitude of unregulated expectancy. While admitting that much had been learned concerning the pathology and treatment of the disease, he declined to admit that an operation must be regarded as indispensable unless and until pus had been shown to be actually present. He described four groups of cases: (1) the sudden, fulminant cases, rapidly proceeding to a fatal issue; (2) the less acute, but still acute, cases in which, after some days, an abscess formed; (3) the ordinary run of cases, as seen in the medical wards in which, after a fortnight or so, the symptoms subsided, and the patient was apparently cured; and (4) the relapsing cases. It was in the third group that he

thought the physician had still a useful sphere of action, and incidentally he remarked on the value of small doses of opium. In view of prognosis, he attached most importance to an increase in the rapidity of the pulse. Each case must be judged on its merits, and he deprecated any dogmatic rules to the effect that the patient must be allowed to pass so many days or must have had so many relapses before the question of operation was decided.

Mr. A. Barker thought the infection of the lymphatics, which the author had demonstrated, afforded a sufficient explanation of several very difficult classes of cases, notably those in which there were outbreaks of inflammation at a distance, including subphrenic abscess. He concurred in the view that opium was beneficial, and insisted on the bactericidal powers of the peritoneum, and he said that even in widespread suppuration he was careful to limit his intervention to the smallest possible area of peritoneum.

Dr. F. Smith commented on the fact that in the majority of cases of ulcerated appendix there was no previous history of pain, a point which was also observed in many cases of gastric ulceration. He remarked that even in the post mortem room it was practically impossible to cleanse the peritoneum, and he doubted whether any surgeon could effect it on the operating table. Observations on a large number of autopsies had led him to the conclusion that the most common position for the appendix was behind the cæcum or ascending colon. Surgeons should therefore make their incisions in a spot which would allow of their reaching that region.

The further discussion was adjourned to February 24th.

Obituary.

DR. WILLIAM A. HAMMOND.

THE death is announced of Dr. William A. Hammond, Surgeon-General of the United States Army during the Civil War, long a prominent figure in American medical circles. He graduated at Newport in 1848, and in 1849, when he became of age, he entered the army as assistant surgeon. In 1862, he became Surgeon-General of the army, with the rank of Brigadier-General. He instituted many changes, all in the direction of more efficient organisation, established the Medical Museum in Washington, and, most important of all, suggested and carried out the plans from which resulted publication of the "Medical and Surgical History of the Rebellion." After an unpleasant incident in connection with his administrative conduct he was dismissed from the army in August, 1864, whereupon he resumed the practice of his profession in New York, devoting his attention to nervous diseases, in which he soon acquired a recognised position. He was also professor of mental and nervous diseases in the Bellevue Medical College, retiring from this post in 1882 to become one of the founders of a Post-Graduate Medical School, removing, some years later, to Washington where he afterwards resided. In 1879 he was restored to his place in the army as Surgeon-General, and retired with his old rank of Brigadier-General.

Correspondence.

We do not hold ourselves responsible for the opinions of our correspondents.

BACON RASH.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—In reply to the query contained in your last issue, perhaps I may be allowed to remark that instances of this form of "alimentary idiosyncrasy" are by no means rare, though I cannot remember bacon in particular having been mentioned as the source of the trouble. Pig flesh, however, is known to cause cutaneous eruption of the urticarial type in a comparatively large

number of persons; while cheese, eggs, certain vegetables and fruits are often incriminated.

It simply amounts to the fact that certain people are unable to digest particular articles of food, and failing proper digestion we get intestinal fermentation with its cortege of symptoms.

In some cases I have been able to convince myself that the disability is purely imaginary, the idea dating from a digestive disturbance of fortuitous occurrence. When the attention of the alleged victim of the idiosyncrasy has been diverted from the dish no ill-effects have followed. I have seen the same thing happen to Englishmen who have been beguiled into eating frogs' legs. Until they were apprised of the nature of the diet all went well, but no sooner did they learn its nature than they experienced nausea and even vomiting. A sudden emotion, such as intense disgust, may, even if retrospective, temporarily arrest or hinder digestion, whence the evolutions of the familiar symptoms.

I am, Sir, yours truly,

CREDÉ.

Literature.

ALLBUTT'S SYSTEM OF MEDICINE. (a)

THIS monumental work has at last been brought to a successful conclusion, at least we presume so from the fact that the present volume contains a general index that it is the last. It is comprised in eight volumes, the first of which was published in 1896. It contains about 7,770 pages, exclusive of the indexes and not counting the 'System of Gynecology.' It has involved the expenditure of about 4,000,000 words. Each volume is published at 25s. net., so that the total cost of the set, including the gynecology, is £11 5s. Among the contributors are to be numbered some of the most brilliant medical writers of the day. It has been the medium of publication of much good original work, some of which will have an enduring influence on the progress of medical science. To whom should be assigned the credit of having contributed the best article it would be difficult to say, and we have no desire to undertake so onerous a duty. That some of the articles have been lamentably feeble is generally acknowledged; but here again it would serve no useful purpose to indicate them by name. The good articles will be read and carefully studied, whilst the poor and indifferent ones will be ignored. Comparing the volumes we are inclined to assign the palm to Vol. VII., although all the articles on diseases of the nervous system are of a very high order of merit. Vol. I. was somewhat unsatisfactory, and the inclusion of an article on Nursing by a lady connected with a Union Workhouse, excited unfavourable criticism. That many of the articles, not only in that but in the succeeding volumes, would have been better for judicious pruning is obvious.

The volume before us contains the remainder of the "Diseases of the Nervous System," commenced in the sixth volume, "Mental Diseases," and "Diseases of the Skin." Most of the articles are short, a fact which may be gathered from the circumstance that no less than 42 authors have been concerned in the production of this volume. The first article, on "Craft Palsies," is by Dr. Vivian Poore, whose name one naturally associates with this subject. It is written in his characteristically vivid style, and deals with such diseases as writer's cramp, telegraphist's cramp, and sawyer's cramp. He calls especial attention to hephestic palsy, which occurs in those who wield light hammers for forging such articles as nails and the blades of pen knives. He also includes in this category miner's nystagmus, which is clearly a craft palsy analogous to writer's cramp and similar troubles. Next comes an article on "Spasmodic Wry Neck" or Torticollis, by John Chiene of Edinburgh, a contribution which, although short, is thorough, and contains details

of cases in which neurectomy was performed. Prof. Chiene, in a note or postscript, mentions that his article was written in 1896.

"Facial Spasm" and "Tetany" fall to the lot of Dr. Risien Russell; while Sir William Gowers deals with the somewhat difficult subject of "Paralysis Agitans." We are glad to see that the name shaking palsy is retained, and that the attempt to call it Parkinson's disease meets with but little favour. It must be admitted that our knowledge of the treatment of this distressing malady is very limited, and that the medicinal remedies commonly employed avail but little.

"Migraine" or Megrim has been entrusted to Dr. James Mackenzie of Burnley. We think that it is somewhat disappointing, and that it contrasts unfavourably, especially in the matter of treatment, with Edward Liveing's classical "Contribution to the Pathology of Nerve Storms." Dr. Omerod of whose article in conjunction with Dr. Mott, on "Tabes Dorsalis" in Vol. VII. we spoke in terms of the highest praise, deals with the subject of "Hysteria," and again acquits himself well. He is very cautious in his expression of opinion with respect to the value of the Weir-Mitchell treatment. He enumerates so many conditions in which he considers that the results are "less favourable" that it is not very difficult to read between the lines. Dr. Patrick Manson contributes a weird article on "Latah." It is original, and is well worth reading. It is very short, and it would be a pity to spoil it by making an abstract of it. It is very entertaining, and might be published separately as a Christmas number of the "System of Medicine." The other articles on nervous diseases are of the conventional type and call for no detailed criticism.

The articles on "Mental Diseases" are for the most part by Dr. Savage, Dr. Rayner, Dr. Clouston, Dr. Mercier, and Dr. Fletcher Beach. Dr. David Nicholson, C.B., deals with "Criminal Lunacy in England," and his article is pointed with good stories of his old Broadmoor days. The fact of his being now a Lord Chancellor's Visitor in Lunacy does not appear to have spoilt his ability to tell a good anecdote with plenty of "go" in it. We are glad to find an article by Dr. Outtersen Wood dealing with "English Law and Practice of Lunacy," for there are few men in his special department for whose opinion we have greater respect. His views on the treatment of nervous diseases by hypnotism would be worth reading.

The Skin Department is under the control of several well-known dermatologists, including Dr. Payne, Dr. Galloway, Dr. Stephen Mackenzie, Dr. Radcliffe Crocker, Dr. Colcott Fox, and Mr. Malcom Morris. The selection must have been an extremely difficult one, especially as competition in this department is keen. Dr. Fox leads off with "Erythema," "Lichen Urticatus," "Prurigo," and "Urticaria." His articles are thorough, but he errs on the side of over-conscientiousness especially in the matter of quoting authorities when his own assertion would answer the purpose. Dr. Payne contributes a good, clear, solid article on "Eczema," which is as free as any article on skin disease can be from the endless refinements of the specialist. Mr. Malcolm Morris deals ably with "Parasitic Diseases of the Skin," and manages to get a good deal of useful information in a very small compass. His article is practical, and he does not trouble much about other people, but tells his story in terse, vigorous language. There are many articles in this volume which, although doubtless of very great interest to the pure dermatologist will, in all probability, be rarely referred to by the general physician. As examples, we may mention "Rhinoscleroma," "Ainhum," "Craw-craw," "Xanthoma," "Mycosis fungoides," and "Darier's Disease."

GADD'S SYNOPSIS OF THE BRITISH PHARMACOPOEIA. (a)

THIS is a most useful little book and one which

(a) "A System of Medicine. By Many Writers." Edited by T. Clifford Allbutt, M.D., F.R.S. Vol. VIII. London: Macmillan & Co., Limited. 1899.

(a) "A Synopsis of the British Pharmacopoeia, 1900." By H. Wippell Gadd, with analytical notes and suggested standards by C. G. Moor, M.A.F.I.C., Public Analyst for the City of Exeter. 4th Edition. London: Balliere Tindall and Cox, 1900. Price 1s.

cannot fail to prove of value both to students preparing for examination and men engaged in active practice. It contains a complete table of all the chemicals, drugs and preparations in the *British Pharmacopœia* of 1898 with their characters, doses and other particulars. It is all so conveniently arranged that the *Pharmacopœia* itself is superfluous. It can be carried in the vest pocket and is available for reference at a moment's notice. The analytical notes are excellent and will be of great use to public analysts.

AITCHISON'S MEDICAL HANDBOOK. (a)

THIS is the third edition of an excellent little handbook for the use of practitioners and students. Within the brief compass of some three hundred and fifty pages an immense amount of material is condensed, yet the production is in no sense of the word a cram-book. Many busy practitioners require from time to time to refresh their minds by a systematic review of medicine brought concisely in line with modern progress. For such a requirement it would be difficult to imagine a work more fitted than the present, which is a marvel of condensation. The complex and wide subject of nervous diseases is well treated. Wisely, as we think, the author has contented himself with a classification of skin diseases, and has thus avoided the perfunctory section upon that complex branch of medical study which the writers of kindred books sometimes present to their readers. The book requires somewhat close reading, but the more one dips into its pages the more it becomes evident that no detail of importance is omitted. In dealing with so wide a subject a result of that kind connotes most careful and skilled authorship. The publishers may be congratulated upon the high standard of this volume.

NORMAN WALKER ON SKIN DISEASES. (b)

OF recent years British writers have not distinguished themselves by any great discoveries in dermatology. It is therefore a real pleasure to meet a writer who not only displays originality but who also has the courage of his opinions. Such an author is Dr. Walker, whose views in some instances differ widely from those of orthodox dermatology. He constantly quotes Unna, an indefatigable worker in the histology of the skin and an acknowledged authority in many branches of dermatology.

Dr. Walker apparently refuses to worship at more than one shrine. Take, for instance, seborrhœa, in which Unna's views as to the micro-coccus are adopted, but no mention is made of Sabouraud's observations and experiments upon a small bacillus found in seborrhœic hairs. Dr. Walker regards psoriasis as a form of seborrhœic dermatitis, a view which, however startling, is already held by some few dermatologists. He does not mention the fact, however, that the original observation that at once cut off a great class of scaly eruptions from the entity known as "psoriasis" was published some years since at the Newcastle meeting of the British Medical Association. While in the critical vein we must protest against the mistaken jocularity that here and there mars these pages. Thus in speaking of scabies he writes, "the removal of the clothes . . . seems to be to the acari an intimation that the time for their nightly prowling has arrived." Again: "Mr. Hutchinson says that arsenic is our *sheet-anchor* in treatment (i.e., of pemphigus). It is fortunate that our mercantile marine have more reliable anchors than that furnished by arsenic in this disease." In dealing with the etiology of urticaria Dr. Walker refers to a large number of blood-borne irritants as "internal irritants," a term that was received with derision some ten years ago but is now becoming adopted by various writers upon dermatology. He does not regard these internal irritants as reflex in their action, but shelves the difficulty of any precise

theory or conclusion by saying they are probably "poisons" brought by the blood stream to the skin. How do they then act? Curiously enough, acute and chronic urticaria appear to have escaped formal description. For the general arrangement of the book, for its clearness, its thoroughness, its practical bent, its freedom from mere academic trammels we have nothing but praise. We have no hesitation in saying that in future editions we look forward to being furnished with a handbook of which the Scotch school may be proud. At the same time, the literary style demands careful revision. The numerous illustrations, coloured and otherwise, are of high artistic merit.

SMITH'S DIFFERENTIAL DIAGNOSIS. (a)

THIS is an excellent book, which gives in terse form much information that the physician has hitherto had to think out for himself. It may be best described, perhaps, as a critical analysis of clinical symptoms founded on a wide bedside experience, and based on a sound knowledge of physiology and pathology. The essential significance of signs and symptoms is the key to the author's method, and they are discussed both as standing alone and in their relation to groups of local diseases. The section on diseases of the urinary organs is particularly clear and full, and will act as a sketch map to any medical man who is investigating an obscure case of renal origin. An extremely practical point is the differential diagnosis of alcoholic coma; nowhere else in medical literature do we recall any account of so full and careful a nature. Assuredly every medical resident in hospital, to say nothing of police surgeons and general practitioners, should lay these maxims to heart. If more stress were laid upon such necessary knowledge in the course of medical education there would be less heard of the constantly-recurring scandal which is announced in the newspapers under the heading "Drunk or Dying." The index of this excellent volume bears signs of haste. We do not find, for instance, any mention of enteric fever. Widal's test for that disease—spelt in the text, by the way, as "Weidal"—is omitted from the list, nor is it mentioned under typhoid or enteric fever. Dyspepsia *v.* heart pain is given as p. 32, when it should be sixty-two. However, these are not very serious flaws. A somewhat striking omission in the body of the book is that of dropsy. Surely a differential diagnosis of the varieties of so common a sign would be of importance to medical men who are every day being called upon to investigate its bearing upon diagnosis and prognosis. Any little imperfections, however, of this kind will doubtless be cleared up in future editions. We welcome this contribution to current medical literature. The number of useless and unnecessary medical books is legion, but here we have a new departure that is shown by a glance to have more than justified its existence. Dr. Smith may therefore be assured that his book falls within the category of the useful and the desirable.

PYE'S SURGICAL HANDICRAFT. (a)

THE fourth edition of this useful little manual, owing to the death of the original author, has been revised and edited by Dr. Bertram Rogers. The fact that another edition is called for is in itself sufficient testimony as to the need of such a work, the aim of which has always been essentially practical, a point that has been steadily maintained in sight of the present issue. In the section dealing with catheters the importance of cleanliness is properly insisted upon, although we think the passage fails in emphasis where it says, "it is a question whether the duty of cleansing catheters after use should ever be left to nurses or porters." So far as that goes we fancy no careful surgeon would trust the cleansing of his catheters to anyone other than himself. Some trust-

(a) "A Medical Handbook." By R. S. Aitchison, M.D., F.R.C.P.E., late Medical Officer, Out-patient Department, Edinburgh Infirmary. Third Edition. Numerous Illustrations. London: Chas. Griffin and Co. 1899.

(b) "Introduction to Dermatology." By Norman Walker, M.D., F.R.C.P.Ed., Asst. Phys. Diseases of Skin, Edinburgh Royal Infirmary. Bristol: John Wright and Co.

(a) "Differential Diagnosis with Clinical Memoranda." By F. J. Smith, M.A., M.D.Oxon., Physician and Senior Pathologist to the London Hospital. London and New York: Macmillan and Co. 1900. Price 7s. 6d.

(b) "Pye's Surgical Handicraft." Edited by Bertram Rogers, M.D.Oxon. Fourth edition. Illustrated Bristol: Wright and Co. 1900.

worthy means of cleansing soft catheters is still urgently needed. Then, when we come to hypodermic injections the need of sterilising syringe, fluids, and so on is not mentioned at all, while the important point of antitoxin administration is dismissed in a few words. The articles on aural and dental surgery have been revised. On the whole, Dr. Rogers may be congratulated upon the way in which he has performed his task, and preserved the spirit of Mr. Pye's original work while adding to its detail and bringing its subject-matter up to date. As everyone knows, a great many of the things dealt with in these pages, although essential to everyday practice both inside and outside hospital, are not described elsewhere. We have no doubt that among practitioners, especially hospital residents and students, this book will not only retain but add to its old reputation.

ASHBY & WRIGHT'S DISEASES OF CHILDREN. (a)

THE first as well as the latest edition of Ashby and Wright's work lies before us. The former is dated 1889. In ten years four editions have appeared. The first consisted of 681 pages with 138 figures; the last has grown to 872 pages with 217 illustrations and fourteen plates.

This product of the Manchester School of Pediatrics has from the first received a well-merited welcome. It is probably the most concise and complete work on diseases of children in English judged from the standpoint of the practitioner and senior student. It is especially practical. The basis of the authors' work is their experience at the Manchester General Hospital for Sick Children. The collaboration of physician and surgeon has ensured a complete and comprehensive presentation of the ailments of childhood.

In the present edition the whole work has been thoroughly revised, and many of the chapters have been entirely rewritten. Considerable additions have been made to the text, and, as already indicated, some sixty pages, twenty-five new photographs and fourteen plates have been added. Mr. Alexander Wilson has also re-written his valuable section on anæsthetics.

This work is so well known, and so highly prized that any special recommendation of the new edition is unnecessary. Nevertheless, it is pleasing to note that the additions, and revisions are such as will greatly enhance the value of the book for practical purposes.

Separate chapters are now devoted to infantile scurvy, rickets, and tuberculosis. The section on the diseases of the blood and blood making organs has been considerably extended. The introductory remarks on affections of the nervous system will prove of particular service. The pages devoted to mental affections in childhood will be of deep interest to the many now devoting their time and attention to the care and training of backward and defective children. In connection with the consideration of renal new growths now recognised as of such importance in children, the authors make due reference to the recent researches of Dr. Kelynack, another member of the Manchester School. The sections on bones and joints, as would be expected from the pen of such an experienced surgeon as Mr. Wright, are admirable. The new skiagram illustrating "travelling acetabulum" in hip disease is of much interest. Other skiagrams illustrate club-hand, congenital dislocation of hip and separation of epiphyses.

The Appendix contains useful notes on modified milk, milk sterilisers, antipyretic methods, narcotics, purgatives, ferments, gavage, enemata, the physiological alphabet, and many other points likely to be of particular service to young practitioners.

No junior medical practitioner can consider his armamentarium complete without this book. In size, substance, and manner of presentation it stands out as the ideal work for the busy general practitioner. The present edition will do much to more firmly establish this joint production as our best English handbook on the diseases of childhood.

(a) "The Diseases of Children. Medical and Surgical." By Henry Ashby, M.D., F.R.C.P., and G. A. Wright, B.A., M.B., F.R.C.S. Fourth Edition. Thoroughly revised. London: Longmans, Green and Co. 1899. 25s.

HEALTH ABROAD. (a)

THIS timely work is evidence of the growing interest which Englishmen are taking in men and things outside their "island home." Insular prejudices are being swept away by the spirit of Imperialism and a deep and scientific interest is now taken in all matters which influence the health of those who travel or reside in countries the climate of which may in any way prove pathogenic. The enthusiasm for researches on tropical diseases, awakened study of medical climatology, and numerous recent publications on the relations of travel to health, all indicate an eagerness for the conquest of disease as well as it may be for the acquisition of territory.

The main object of the present work is to enable the ordinary traveller to preserve his health whilst travelling in unknown climates, to be familiar with the various emergencies which may arise when medical aid is not forthcoming, and to treat them to the best advantage.

The articles have been written by those who have had personal experience of the district or country they describe.

The editor is rightly careful to impress his readers with the fact that the "work is not intended to obviate the necessity of seeking medical aid." He points out very truly that "matters which at home are of small moment are, in a new climate, and under unaccustomed conditions of travel, often apt to be either serious in themselves from the beginning, or to become serious if left untreated or treated improperly, so that no time should be lost in seeking skilled advice."

Two difficulties are experienced in producing such a work as this. First that there is a great similarity between the conditions which are unfavourable to health in various parts of the world, and between the diseases which are in fact chiefly prevalent, and secondly that there are numerous local diseases, or varieties of diseases, which cannot be dealt with in detail.

The editor and his contributors are to be heartily congratulated on the admirable way in which they have dealt with a particularly difficult subject. The various articles are of course somewhat different in style and vary in arrangement, but even this variation is beneficial as each contributor seems to have treated the country he describes chiefly according to the reasons for which travellers go thither.

As far as we have been able to ascertain the book is peculiarly accurate in its descriptions, sound in its judgments, and safe in the character of its advice. We have no hesitation in strongly recommending it to the careful consideration of all "about to travel."

A list of English medical men practising in foreign countries is given, and is likely to be of convenience to travellers wishing to be attended in case of sickness by one of their own countrymen.

The work is furnished with a good index.

We could have wished that a few maps had been included. It would have added greatly to the interest and practical value of the volume. We trust that such may be supplied in the next edition, and would suggest that the routes generally followed by travellers in search of health be clearly indicated thereon.

RIEDER'S ATLAS OF URINARY SEDIMENTS. (b)

THE publishers are entitled to the thanks of the profession for having placed this magnificent work at its disposal. Dr. Rieder's atlas, containing as it does, thirty-six plates, comprising no less than 167 figures, many of them in colours, is far and away ahead of any work of the kind with which we are acquainted. All urinary sediments of any importance are represented, only a few of the very rare ones having designedly been omitted. In

(a) "Health Abroad: a Medical Handbook of Travel." Edited by Edmund Hobhouse, M.D. Pp. 372. London: Smith, Elder, and Co. 1899.

(b) "Atlas of Urinary Sediments." By Dr. Hermann Rieder, of the University of Munich translated by Dr. F. C. Moore, Assistant Lecturer and Demonstrator of Pathology at Owens College, Manchester. Edited and annotated by Dr. A. Sheridan Depine, Professor of Pathology at Owens College and Victoria University, Manchester. London: Charles Griffin and Co., Ltd. 1899.

addition to the plates, which are works of art in their way, we have a translation of the original text, in which special stress is laid on the characters, the mode of occurrence and the pathological significance of the various urinary sediments. In respect of the inorganic or crystalline sediments it has been thought well to give some of the micro-chemical reactions because the crystalline form alone is not, in every instance, a trustworthy guide to diagnosis.

The English editors have added explanatory notes and a full bibliography, and they have been good enough to supply an alphabetical index, for which their readers will be duly grateful.

We have nothing but praise for the manner in which the translator and English editor have done their work, but the author's text is itself characterised by lucidity and even terseness. The printing of the plates leaves nothing to be desired, and since the same magnification has, as far as possible, been employed, the relative size of the various constituents is readily grasped and appreciated.

Laboratory Notes.

"TROPON."

THERE is scope in the field of what we may call scientific alimentation for palatable and readily digestible products rich in nitrogen. Dried and powdered meat, for a time, held the market, but such a product is necessarily unstable and of variable composition, and its popularity as a means of securing adequate nourishment has waned. We have just had an opportunity of examining a new, highly albuminous food, to which the name *Tropon* has been given. *Tropon* is a light-brown, almost tasteless powder, derived, we are informed, from raw vegetable and animal materials. It is not hygroscopic, and, if kept dry, is practically free from any tendency to decomposition. Our analysis of the dried powder gives the following results:—

Moisture	...	...	11.0 per cent.
Mineral matter	...	...	10 "
Albuminoids	...	...	88.0 "

which closely accords with the analyses made by others. Weight for weight it will be seen that *Tropon* contains nearly four times the amount of flesh-forming constituents present in good average meat. It is not soluble in water, but, as experiments show, it is readily amenable to the action of pepsin.

It is given mixed with milk or soup, the taste whereof is not modified thereby to any appreciable extent, though their nutritive powers are enormously enhanced.

A NEW VACCINATION IMPLEMENT.

We have received from "The Association for the Supply of Pure Vaccine Lymph" (12, Pall Mall East, London, S.W.), an ingenious innovation having for its object to supply an instrument sufficient in itself for an aseptic vaccination. It is very simple in construction and use. Briefly described, it consists of a needle with a flattened point, embedded in a glass head, the crown of which is hollowed out to receive the lymph. This, when *in situ*, is covered with a metallic diaphragm, and a cap, the whole being sealed hermetically by melted paraffin. The operation consists in scratching the arm with the point in the selected spots, then, pushing off the capsule with the thumb-nail, the glass head is applied to the skin near a place of insertion. By moving the hand with a gentle pressure the diaphragm is left behind and the vaccine should then be well rubbed into the abraded surfaces. The proportion of successes by this method is very high, ranging from 93 to 100 per cent. Asepsis is practically secured, and the chances of failure are practically eliminated. The charged needles are supplied at the price of sixpence each, the vaccine being sufficient for from three to five vesicles.

Medical News.

The Teaching of Pathology at Westminster Hospital.

THIS Institution has of late shown strong evidence of unimpaired vitality, the energy of its staff finding outlets in various directions. This we doubt not will meet with the success it deserves. Dr. Lazarus Barlow announces that he will hold the following classes in Pathology:—1. An elementary course of lectures and practical work on Monday, Wednesday, and Friday mornings from 10 to 12.30. Commencing Jan. 15th and ending in July. Fee for the whole course, £15 15s. 2. A revision class for University and other higher examinations, meeting on Tuesday, Thursday, and Saturday mornings from 10 to 12.30. Each day a lecture will be given on some selected point in pathology, and this will be followed by microscopical work. Commencing January 30th and continuing eight weeks. Fee £7 7s. Special classes will also be held in anatomy and physiology every three months for the second conjoint and hall examinations by Mr. Paton and Mr. Canny Ryall, at which students who have not passed can make the necessary attendances at these classes. Fee £3 3s. each subject. The Dean will supply full particulars.

Bradford and District Medico-Ethical Society.

THE annual general meeting of this Society was held on January 17th, 1900. The officers elected for the ensuing year were as follows:—President, Dr. J. H. Bell; vice-president, Dr. D. Goyder; hon. treasurer, Dr. F. K. March; hon. secretaries, Drs. W. Horrocks and A. Manknell; committee, Drs. Mossop, Parkinson, Bronner, Harrison, Handcock, and Metcalfe; auditors, Drs. Arnold, W. Evans, and Peck. Certain alterations were made in the rules of the Society.

A Negligent Public Vaccinator.

MR. AVERILL, the public vaccinator for the district of Longton, Stoke-upon-Trent, appears to have an insurmountable repugnance for the literary part of his functions, and at a recent meeting of the Guardians it was stated that in spite of much urging he had failed to send in any returns for over twelve months. In consequence it was decided to give him a month's notice to terminate his appointment.

University of Oxford.

THE following candidates passed at the recent examinations:—

FINAL EXAMINATION FOR THE M.B. DEGREE.

Pass List.—A. C. Goodwin, B.A., Kelle; F. P. T. Hilliard, B.A., Magdalen; F. O. Stoehr, B.A., Trinity; and J. A. Willett, B.A., University.

Pathology alone.—E. D. Bond, B.A., Kelle; J. D. Rolleston, B.A., B.N.C.; J. E. H. Sawyer, B.A., and W. V. Shaw, Christ Church; F. J. Stevens, M.A., Exeter; A. E. Thomas, B.A., Merton; and B. Warren, B.A., New.

FIRST EXAMINATION FOR THE M.B. DEGREE.

1. Organic Chemistry.—G. D. Allen, non-collegiate; G. Hely-Hutchinson Almond, Hereford; L. T. Burra, University; E. Hurstall, Trinity; v. Davidson, Brasenose; H. R. Dean, New; J. Freeman, University; R. C. Jewsbury, Christ Church; H. A. Philpot, New; E. Whitley, Trinity; and A. R. Wilson, Wadham.

2. Materia Medica and Pharmacy.—T. E. Cole, Christ Church; W. L. M. Day and A. C. Le Rossignol, Exeter College; and A. J. Wigmore, non-collegiate.

3. Human Anatomy and Human Physiology.—E. L. Farncombe, St. John's; A. H. Hogarth, Christ Church; C. M. H. Howell, Trinity; L. D. Neave, Merton; and P. F. Tine and H. M. Turnbull, Magdalen.

* Offers Human Anatomy only, being exempt from examination in Human Physiology.

Society of Apothecaries of London.

The following candidates have passed the examinations:—

Surgery.—T. P. Allen, J. R. Bentley, C. H. Brookes, A. McC. Dallas, J. M. Edwards, W. St. G. G. Hill, D. T. C. Jones, E. C. Scarlett, H. E. Weston, T. R. Wilshaw.

Medicine.—F. G. Aldrich, A. St. J. Bateman, C. H. Brookes, P. Cator, D. T. C. Jones, E. C. Scarlett.

Forensic Medicine.—C. H. Brookes, A. McC. Dallas, D. T. C. Jones, L. G. W. Tyndall.

Midwifery.—A. H. Bell, P. C. Burgess, A. A. F. Clarke, J. S. Goodall, K. Grube, D. T. C. Jones, E. R. Risien, J. Waters, H. Whitaker.

The diploma of the Society was granted to the following candidates, entitling them to practise Medicine, Surgery, and Midwifery:—

Messrs. J. R. Bentley, P. Cator, J. M. Edwards, K. Grube, W. St. G. G. Hill, E. C. Scarlett, H. E. Weston, and H. Whitaker.

Notices to Correspondents, Short Letters, &c.

✉ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

INFIRMARY NURSES AND DANCING

SIR.—An editorial with the above heading appears in the *MEDICAL PRESS* and *CIRCULAR* for January 17th, in which certain incidents are alleged to have taken place at Fulham Infirmary. May I point out that so far as *this* Infirmary is concerned the whole of the charges are absolutely baseless? Will you kindly correct the error in your next issue?

I am, Sir, yours truly,
C. T. PARSONS, M.D.Lond.

Fulham Union Infirmary,
St. Dunstan's Road, Hammersmith.
January 19th, 1906.

UN-PROFESSIONAL ADVERTISING.—Our attention has been called to an advertisement which appears in a Clonmel paper, bearing the signature of a Mr. Redington, who states that he is a Fellow of the Royal College of Surgeons, Ireland, and which puts him forward as a candidate for the position of Medical Superintendent of the Clonmel District Asylum, he being, at present, Assistant at the Richmond Asylum, Dublin. We regret to observe that it seems to be necessary for us to remind this gentleman, first that it is quite unusual for any self-respecting member of our profession to placard his election claims in the lay newspapers, and that any practitioner who does so must expect (and deservedly) the reprobation of his fellows; secondly, that the Bye-Laws of his College, which he swore to observe, prohibit absolutely this method of seeking notoriety, a fact which appears to have escaped his memory. We have, furthermore, to add that the advertisement, as it stands, would be much more suitable as the manifesto of a village stump politician than of a professional gentleman seeking a public medical office, as it places Mr. Redington's claims to appointment almost wholly on the ground of politics and religion, and lays little stress on his competency for the performance of the required duties. In our opinion, the whole thing is anything but creditable, in the professional sense, to the advertiser.

THE LIMITS OF MEDICINE.

A PREY to ill-health for many years, a certain octogenarian reproached his doctor with not having afforded him any relief. "I am sorry," replied the doctor, with a sympathetic smile, "but it is less my fault than that of your age. I can't make you grow younger." "Nor do I ask so much," retorted the patient, "all I ask is to be enabled to go on growing older for some years more."

COLONIAL SURGEON.—The facts are well known, but we doubt the expediency of acting upon them just at present.

OPTICIAN.—The custom is one better honoured in the breach than in the observance.

LAYMAN.—Our correspondent has not shown much wisdom in studying medical books.

DR. G. D. ROBINSON will find the notice he sends for publication has already appeared in our columns three weeks ago, on page 20, January 3rd.

MR. J. E. R. STEPHENS.—The matter shall be considered, and a private note sent you in due course.

MR. BASIL HALL is thanked for his communication.

THE DOCTORS' STRIKE.

ALLUDING to the action of the doctors in a certain country town where for some reason they had "gone on strike" one of the inhabitants asked anxiously what would happen. The only resource, his friend replied, is for the patients to strike too.

Meetings of the Societies and Lectures.

WEDNESDAY, JANUARY 24TH.

DERMATOLOGICAL SOCIETY OF GREAT BRITAIN AND IRELAND (20, Hanover Square, W.).—4.30 p.m. Informal Exhibition of Cases. 5 p.m. Ordinary Meeting.

SOCIETY OF ARTS.—8 p.m. Mr W. O. E. Meade-King: Local Government and its Relation to Parish Water Supply and Sewerage.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN (Leicester Square).—4.30 p.m. Dr. T. D. Savill: Lupus Vulgaris. (Post-graduate Course.)

THURSDAY, JANUARY 25TH.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.—8 p.m. Patients and Card Specimens. 8.30 p.m. Papers.—Dr. W. Edmunds: Experimental Exophthalmos and Enophthalmos.—Mr. A. Lawson: Corneal Horns.—Mr. C. H. B. Shears: Acute Glaucoma following a Single Application of Hematropine.—Mr. W. M. Beaumont: Family Tendency to Ophthalmoplegia Externa.

BRITISH BALNEOLOGICAL AND CLIMATOLOGICAL SOCIETY (20, Hanover Square, W.).—8.30 p.m. Discussion on the Treatment of Nervous Diseases and Affections by Baths and Climate (introduced by Dr. H. Campbell).

FRIDAY, JANUARY 26TH.

CLINICAL SOCIETY OF LONDON (20, Hanover Square, W.).—8.30 p.m.

Papers:—Mr. J. Hutchinson, jun.: Two Cases of Successful Primary Resection of Gangrenous Small Intestine.—Mr. Pearce Gould: A Case of Bullet Wound of the Abdomen with Four Wounds of Small Intestine and Two of the Mesentery, Operation, Recovery.—Dr. Rolleston: A Case of Fatal Hæmopneumothorax of unexplained origin.

Appointments.

CLEGG, J., M.B.Lond., M.R.C.S., an Honorary Medical Officer to the Urmoston Cottage Hospital.
DINGWALL, A., M.B., C.M.Aberd., Medical Officer for the Kinsham and Pembroke Sanitary District of the Kingston Union.
JENKINS, HERBERT, L.R.C.P.Lond., M.B.C.S., House Surgeon to the Bristol Royal Hospital for Women and Children.
LEADER, HAROLD, M.B., House Physician to the East London Hospital for Children and Dispensary for Women, Shadwell.
QUAYLE, EDWIN, L.R.C.P.Lond., M.R.C.S., an Honorary Medical Officer to the Urmoston Cottage Hospital.
SAUNDERS, E. SYMES, M.D., C.M.Aberd., Medical Officer to the Dispensary, Royal Albert Hospital, Devonport.

Vacancies.

Bath General or Royal Mineral Water Hospital, Bath.—Resident Medical Officer, unmarried. Salary £100 per annum, with board and apartments.
Birr Union.—Trained Fever Nurse. Applications to the Clerk of the Union before February 3rd. Salary £40, with board and lodging. (See Advt.)
Chester General Infirmary.—Visiting Surgeon for two years. Salary £80 per annum, with residence and maintenance in the house.
City of Liverpool.—Visiting Physician to the City Hospital North,etherfield Road. Salary £130 per annum. Applications to the Town Clerk, Liverpool.
Croydon.—Medical Officer of Health for the Borough. Salary commencing at £500 per annum. Apply to the Town Clerk, Town Hall, Croydon.
Loughborough and District General Hospital and Dispensary, Loughborough.—Resident House Surgeon. Salary £100 per annum, with furnished rooms, attendance, and board.
Metropolitan Asylums Board.—Three Assistant Medical Officers at the Fever and Small-pox Hospitals, unmarried. Salary commencing at £160 per annum, with board, lodging, attendance, and washing. Applications to the Clerk to the Board, Norfolk Street, Strand, London.
Nottingham City Asylum.—Second Assistant Medical Officer, unmarried. Salary £125, with board, apartments, and washing.
Nottingham General Dispensary.—Assistant Resident Surgeon. Salary £140, per annum. Special arrangement made as to board &c.
Nottingham General Hospital.—House Surgeon for two years. Salary £100, rising £10 a year to £120, with board, lodging, and washing.
Plymouth Borough Asylum. Assistant Medical Officer, unmarried, Salary £125 per annum, rising to £150, with furnished apartments in the Asylum, board and washing free.
Salisbury Infirmary.—House Surgeon, unmarried. Salary £100 per annum with board, lodging, and washing.
Western Dispensary, Rochester Row, Westminster.—Resident Medical Officer, unmarried. Salary 100 guineas per annum, with furnished rooms, coals, gas, and attendance. Apply to the Secretary.
Worcester General Infirmary.—Assistant House Surgeon and Dispenser for two years, unmarried. Salary £70 per annum, with board, residence and washing.

Births.

BRODIE.—On the 16th inst., at Fernhill, Wootton, Isle of Wight, the wife of C. Gordon Brodie, F.R.C.S., of a daughter.

Marriages.

BRIDGEFORD — CUMBERLAND.—On December 13th, 1899, at St. George's Church, Victoria, Australia, Walter Bridgeford, M.R.C.S.Eng., L.R.C.P.Ed., of Boulder, W. Australia, to Florence, daughter of the late Capt. R. F. W. Cumberland, Manchester Regiment.

PLUMMER—MOXON. On January 17th, at St. Nicholas Church, Great Yarmouth, Selby W. Plummer, M.D., of Durlam, to Jillian, daughter of the late Thomas Hy. Moxon, M.R.C.S., of Great Yarmouth.

Deaths.

BRADY.—Killed in action at Kimberley. Geo. C. Brady, son of the late G. Frazer Brady, M.D., F.R.C.S., of Falcarragh, Co. Donegal.

COLLUM.—On January 12th, at Surbiton, Robert Collum, M.D., M.R.C.S., M.B.C.P., aged 84 years.

MANBEY.—On January 13th, at Stanley Villa, Stanley Road, South Acton, George Manbey, M.R.C.S.

ROBERTS.—On January 12th, at the Hawthorne, Croyley Green, Herts, John Henry Roberts, F.R.C.S., in his 87th year.

VERNON.—On January 20th, at his residence Southport, Hy. Hannote Vernon M. Ed., M.R.C.S.Eng., Medical Officer of Health for Southport, aged 68.

WATLINGTON.—On January 19th, at 1, Randolph Gardens, London, N. W. Y. Victor Watlington, M.D.Ed., of Puerto Rico.

The Medical Press and Circular.

THE CO-RELATION OF SEXUAL FUNCTION WITH INSANITY AND CRIME. (a)

By H. MACNAUGHTON-JONES, M.D.,
M.A.O., M.CH., &c.,

President of the British Gynaecological Society.

(Concluded from page 80.)

CLIMACTERIC INSANITY.

CLIMACTERIC insanity occurs both in men and women, but, as Clouston has shown by his statistics, in a much larger proportion of women, 196 to 32 out of 228 cases. The ten years from forty to fifty are the ones he regards as most favourable to the development of the insanity. It is, he says, a sub-acute psychosis, as mania is not nearly so common as melancholia, and suicidal impulse occurs in fully 50 per cent. of the cases, an important practical point being that such suicidal impulse is difficult to prognose so far as the intensity of the suicidal desire, and that such patients have to be always surrounded by every care and precaution against the impulse.

It is interesting to note the pathological changes that occur in senile ovaries, when alluding to that form of insanity that Clouston calls ovarian, which occurs in old maids, the combined effects of an unprepossessing appearance, with a too great devotion to religious exercises, "severely virtuous in thought, word, and deed," "in whom nature, just before or after the climacteric, takes revenge for too absolute a repression of all the manifestations of sex."

Otroschkevitch has shown that in old age the epithelium covering disappears from the surface of the ovaries, that there is desiccation of mature, and wholesale degeneration of the primordial follicles, attended by hyaline degeneration of the arteries and the fibrous tissue, and finally fatty degeneration of the cellular tissue. Here we must have a corresponding decrease in the ovarian secretion.

Here is a case in point. A lady, unmarried, and passing through the climacteric, was brought to me for the removal of a comparatively small uterine polypus. For some time her manner had altered towards her relatives, and she was more taciturn and morose, but there had been no direct evidence of any marked mental alienation. I determined to remove the polypus, but was so struck with the manner of the patient, that in placing her in the Medical Home I asked the superintendent to obtain a special mental nurse to look after her. The next morning she was taking her breakfast, nothing whatever having occurred in the meantime to excite suspicion, and while the nurse was placing something outside the bedroom door, having foolishly allowed a knife on the tray, the patient cut her throat in two places, fortu-

nately not fatally. I subsequently removed the growth in an asylum, but I am not aware that she ever recovered her sanity.

To show how persistent and obscure, with long intervals of suspension, these climacteric impulses may be, I may mention the case of a lady, sent to me by the late Dr. Hack Tuke, who had prolapse of the uterus, with attendant bladder symptoms. She suffered at times from marital delusions and attacks of melancholia. The prolapse was cured, and the patient relieved. She was supposed to be completely cured, but some years later, without any warning, in a fit of depression she committed suicide by drowning.

Clouston places under a separate heading "hysterical" insanity, an insanity engrafted on hysteria, and groups under this a distinct class of symptoms, such as incessant talking, sexual and erotic ideas, imaginary ailments, craving for notice, habits of masturbation. He says such cases form 50 per cent. of insane females.

I am not referring to-night to puerperal insanity, further than to say that in considering the etiology of this affection, various workers have shown that both in uterine lesions which have existed previous to labour, and the other affections of pregnancy, we have ante-partum warnings of the predisposing causes of this affection, while in lesions occurring during labour, such as severe laceration of the cervix, not treated immediately and rectified, we have the exciting causes of the puerperal mania. The insanity of pregnancy Clouston regards as comparatively rare, occurring in women advanced in life when becoming pregnant, and usually of a melancholic and suicidal character.

There is an important bearing on these cases, as indeed, on all cases of insanity in women, and that is the hereditary alcoholic tendency and proneness to alcoholic nerve degenerations and dipsomania. Sixty per cent. of such cases, Clouston says, recover at childbirth. How far menstruation, epilepsy and insanity are correlated, may be still further deduced from the observations by Sutherland in Hack Tuke's "Dictionary of Psychological Medicine." Briefly, they are as follows:—Esquirol has computed that the disorders of menstruation form one-sixth of the physical causes of insanity, and in this conclusion Morel coincides. In epileptic insanity the catamenia has a marked influence on the fits, increasing these in number or intensity. Menstruation has a like effect in producing exacerbations of excitement in mania, while in sufferers from melancholia, amenorrhoea is frequently present. General paralysis appears to induce an early climacteric, and further, the curious fact is recorded that in a few aged insane women, the catamenia reappear after prolonged cessation. It is worthy of notice that in dementia, menstruation does not appear to be affected, and all the evidence points in the direction that there is a delay in the appearance of the menstrual act in imbeciles, idiots, and cretins.

I have recently had two patients, sisters, both of

whom developed symptoms of insanity. In one it assumed the form of dislike to the parents and delusions regarding them, as well as a suicidal tendency. The first attack occurred with suppression of the catamenia. She quite recovered from this. With a second stoppage of the periods she became the victim of religious delusions. Again, with the re-establishment of the catamenia, she has perfectly recovered. The other sister with the onset of each menstrual period grew excitable, and incoherent, and took sudden violent dislikes even to her parents. This mental derangement passed off about a week after the termination of her rather scanty flow. Gradually approaching the next epoch it recurred. She is now perfectly well, and her uterine functions are healthy.

Clouston well sums up the class of symptoms we meet with in patients of this stamp. I may summarise them as follows:—Stupidity and lethargy in some, lack of interest in duty, an anti-social tendency, causeless aversion to relatives, intolerance of control, incompatibility of temper, impracticable visionary scheming and want of common sense; sudden development of unaccountable immorality, or perverted sexual and reproductive trains of thought. Unfortunately, as the writer says, such patients, who really require to be placed in the hands of a doctor, too often find their way into the arms of a policeman.

I have myself recorded two cases which, so far as I know, are unique, of trophic disturbance associated with menstruation. One, which I brought before this Society, 1896, of deep discolouration and pigmentation of the entire side of the face, complicated occasionally with extensive ecchymosis of the cellular tissue of the orbit, in a case of violent dysmenorrhœa, and coming on with the catamenia. The other, which I read elsewhere, and to which I gave the name of "esthiomenic menstrual ulcer of the nose," in which the most serious trophic disturbances, resulting in a form of corroding ulcer of the nose and lip, recurred with each menstrual period, and began with amenorrhœa. Curiously enough, a sister in the same family was subsequently troubled in like manner. The full particulars of the case I refer to were in the *Edinburgh Medical Journal*, 1898.

Hack Tuke (a) in writing on marriage and insanity, notices what he evidently regards as a perversion of feeling, in which young persons of both sexes suffer during a protracted engagement from a revulsion of feeling, and an antipathy is engendered which may lead to a rupture and its legal consequences. Of course, there is one powerful factor in both men and women, which, especially during the development of adolescence, has a strong collateral influence in producing and maintaining erotic desires, impulses, and delusional insanity. Of this I have myself known some marked instances. I allude to the practice of masturbation. Not only has this habit a predisposing influence in the direction of such morbid emotions or delusions, but in many cases it plays a principal part in the production of the epilepsy of puberty.

I can speak from personal knowledge, having had many consultations with him in cases of mental trouble associated with disordered sexual functions, as to how the late Hack Tuke regarded this question. He recognised fully the coincidence of disordered menstruation and disturbance of the mental functions, but was not greatly impressed with the value of a surgical operation on the insane, though, as he stated in the discussion which took place in this Society ten years since, he considered that the operation of oöphorectomy might be indicated in certain cases, and justifiably performed with benefit.

Our distinguished Honorary President on the same occasion held that in cases of nervous derangement, in which disorder of the sexual functions is suspected,

a close investigation as to the state of the sexual organs should be made. There can be no doubt that the view of Spencer Wells, speaking generally, was against operation in such cases. Dr. Savage, in 1890 at that discussion, held that a relatively small amount of success followed examination of the pelvic organs of women. I have had, for the purposes of this address, a valuable letter from Dr. Blandford, whose long experience of the insane makes any opinion emanating from him of special value, and in that—for I have not here time to quote the entire communication—speaking from his forty years of connection with insane cases, the view is strongly upheld that uterine or ovarian disorders are not serious factors in the causation of insanity. He has never had a case of malignant uterine disease, and in only one patient a fibroid tumour, which was developed years after the insanity. He looks upon the cessation of the catamenia and amenorrhœa as rather a concomitant occurrence than as having anything to say to the causation of mental disease, and with regard to operations, he says that he has never known a patient cured by one, and has known insanity to follow in one case. He does not approve of subjecting a woman in a maniacal state to a vaginal examination.

I quote this opinion as expressing, on the part of an experienced alienist, the views of those who are strongly antagonistic to the more modern school, both of alienists and gynecologists, with regard to this question. As one holding possibly what I might call a middle position, I refer to a communication I have had from Dr. Percy Smith, of Bethlem, who also took part in the discussion of 1890. His views are the same now as then. He considers that the number of women in asylums who are supposed to have reached them through diseases of the sexual organs is greatly exaggerated; and, further, that many of the cases which have been admitted to Bethlem Asylum had already been submitted to gynecological treatment for affections of the genitalia, and that the breakdown had come during such treatment and after operation for the local disease. He thinks, in cases of recurrent insanity and where the disorder is most marked at each menstrual period, that while he has no experience of the effect of oöphorectomy, it is worthy of consideration in cases where outbreaks of eroticism, excitement, or stupor, occur at each period, the patient being sane in the intervals; and the amenorrhœa, which is present in acute mental disorders, he regards, in the greater number of cases, as a symptom of the general disorder, and does not believe that it demands a local examination. Nor does he in any way agree with the American suggestion that every woman admitted to an asylum should be examined, regardless of age or symptoms. "The gynecologist must not lose sight of the nervous system, nor the alienist of the pelvic organs."

Dr. Yellowlee, writing to me, says that gynecological operations for the cure of insanity are far from satisfactory in their results, and are not justifiable unless there be proof that there is local disease irrespective of the insanity.

I myself have seen insanity (not climacteric) complicating fibromata, displacements, and adnexal disease—but in every case the history disclosed a pre-existing predisposition to mental obliquity or some distinct form of alienation. Personally, I at present take the view that, in the great majority of cases in which there are gross lesions of the sexual organs present in insane women, and even where the lesion has preceded the insanity, there still has been pre-existent to the lesion what Robert Barnes well calls "an antecedent nervous condition as a predisposing factor."

I lately operated upon a young lady who had been previously confined in an asylum, and who subsequently had the operation of supravaginal hysterectomy performed. The latter step was taken for a fibroma of the uterus, and the adnexa of one side were removed. The discharge from the cervix continuing, and treatment not availing, she consulted me for the affection of the cervix. On examination I found a most unhealthy cervix with a deep and bleeding erosion, and a rather profuse discharge. I removed the cervix, and she recovered perfectly from the operation. But the old symptoms of erotic mania returned, and it became necessary to remove her to an asylum from which she has since been discharged as cured.

I operated upon another case—one of a lady who had held the office of superintendent in a private asylum, and from whom I removed two cystic ovaries. She previously had had curettage twice performed for endometritis and erosion of the uterus. She complained of constant agonising pain in the seat of the ovaries, and dysmenorrhœa. She was a typical specimen of the true neurasthenic and neurotic woman. Not until I had emphatic requests in writing from herself and relatives did I consent to operate, nor would I confess, be in a hurry to accede even under these conditions to such a proposal in a similar case. Twice she deliberately induced a hernia of the wound by her own acts, necessitating a third operation and forcible restraint afterwards to prevent a repetition of this, and then so admirably feigned a condition of dementia that not until the certificates for removal to an asylum were filled, which were really completed in order to test her malingering, did she return to a natural state of mind. This case, though an unenviable experience to me, may, perhaps, be a warning to others.

Mr. Elder and Mr. Furneaux Jordan have both had two cases of post-operative insanity, all of acute mania. The operations were curettage and oöphorectomy, and the diseases ovarian cystoma and myoma.

One of our Fellows, Dr. Halliday Croom, has this year reported a case of acute mania occurring on the third day after simple ovariectomy, the patient dying on the sixth day, and also a second case of acute mania at each menstrual period, which he treated several years since by the removal of cystic ovaries, resulting in a permanent cure.

Elzholtz, of Vienna, has reported a case of suicidal melancholia completely cured by pan-hysterectomy. In this case there was a bleeding myoma. (a)

I have also through Mr. Martin notes of a case. A patient, æt. 42, upon whom he operated in the Warwick Asylum for ovarian tumours, suffered from melancholia, which passed into dementia. The case ended in complete recovery. He refers to two other instances of menstrual mania which were cured by pan-hysterectomy. In the one case four years, in the other two, have elapsed since the operation, and both have completely recovered. On the other hand, he also sends me notes of two cases, one of vaginal hysterectomy for chronic metritis and hæmorrhagic endometritis, and the other a case of pan-hysterectomy for myoma, in both of which insanity followed the operation, one about a week, and the other three weeks, later.

Dr. Japp Sinclair gives me the particulars of an interesting case of a lady who had been confined in the Cheate Royal Asylum. She suffered from a bleeding fibro-myoma, and had been subjected to a long course of expectant and old womanly treatment for the same. Professor Japp Sinclair performed hysterectomy, and though there was an anxious time after the operation, she never again had to return to

the asylum, from which she had been temporarily removed for the purpose of operation.

Dr. Ernest Hall reports another most interesting and instructive case. The patient suffered from intermittent melancholia for nearly three years, and came to be looked upon as a hopeless case in the London Asylum (Montreal). The adnexa when examined, after she had been in the asylum from April, 1895, to January, 1898, were found diseased. Complete recovery followed on oöphorectomy.

Professor Auguste Martin, of Berlin, on whose vast experience I thought it well to draw in writing this address, says that all his experience teaches him that healthy women do not run the risk of insanity from their sexual functions, nor are they endangered as to insanity by operations on their sexual organs. On the other hand, if their mental condition at the time of the operation or previously, be not a normal one, operations on the sexual organs induce mental instability or temporary insanity, the more so in proportion as their physical or mental state have been impaired prior to the operation.

Dr. Wood, of Hoxton, out of eleven cases, admitted to the asylum within ten years, of women who suffered either from climacteric disturbances, or in whom sexual disturbance was attributed as a cause, shows that in one case melancholia had followed removal of the ovaries, in another it supervened after suppressed menstruation, and in another, a senile, prolapsus uteri was present. There was one case of mania of pregnancy, one of the mania of puberty, and six of climacteric insanity. Up to 1890 Keith had six cases of insanity out of 64 hysterectomies, and Savage of Birmingham had records of four cases of insanity out of 483 cases of oöphorectomy.

Mary Dixon Jones, whose opinion as unquestionably the foremost of living women gynecologists, and whose views with regard to epilepsy I have already quoted, (a) referring to oöphorectomy for diseased ovaries and tubes in the case of women so affected who are insane or mentally afflicted, having instanced some such cases, says: "I would not remove healthy or normal ovaries for dysmenorrhœa or any suffering in the regions of the ovaries; I would not remove any save diseased adnexa for epilepsy, nor for mental or neurotic disease, even if I had failed after long trials of tentative measures, and had the cordial, full, and deliberate sanction of experienced practitioners."

George Rohé, of the Hospital for the Insane, Sykesville, who probably as much as any other living psychologist has studied the effects of the operation on women in insanity, and, indeed, also in the case of males, comes to these conclusions with reference to post-operative insanity, that while there is little difference in the two sexes between the number affected, the graver forms follow, in the majority of cases, operations upon the abdominal and pelvic organs in women. He considers that, excluding cases of heredity, or acquired psychopathic predisposition, the mere removal of the ovaries would have no greater psychical effect than the removal of the arm or leg.

Confusional insanity is the form frequently found as post-operative, and both Dr. Rohé and Dr. Hurd of Baltimore, who has written on post-operative insanity and undetected tendencies to mental disease, consider that the great majority of the cases are due to toxæmia from septic infection. "There is no ground for considering," says Dr. Hurd, "that the operation *per se* produces mental disease," and, so far as removal of the ovaries is concerned, a premature climacteric insanity may be developed, but this is due to the loss of the organs, and not to operation." The essential pre-requisite for the development of post-

(a) Vienna Klein Wochenschrift, November 23, 1898.

(a) "British Gynecological Journal," November, 1895.

operative insanity must be in all cases a neurotic organisation predisposed, either from hereditary taint or from acquired nervous weakness, to take on diseased action in consequence of any disturbing influences. Operation should be discouraged in people of this constitution.

Mr. Jesset inclines to this view, that though insanity may occasionally follow gynaecological operations, still, the rule is that the patients recover from the mental disturbance and are ultimately much better for the operative interference.

It was my intention to have referred to other matters in which gynaecology is brought into close relationship with forensic medicine, and where it plays a most important part, as, for instance, in suspicions of chastity and the form and condition of the hymen; gonorrhoea, and the presence of the gonococcus in uterine discharges, and the whole question of scientific pathological evidence as regards wounds of the uterus, the condition of the endometrium, the presence and duration of the products of conception in utero, as well as the pathological differentiation of pregnant and non-pregnant changes in the ovaries. All these considerations seriously affect a correct decision in cases of attempted or produced abortion. Time, however, does not permit of this.

CONCLUSIONS.

On the entire evidence before me, I have come to these conclusions (1) That the correlation of insanity and disordered sexual functions arising out of affections of the generative organs is a factor to be taken into serious consideration in the treatment of women mentally afflicted.

(2) That where there is ground for the suspicion that some physical condition of the uterus or adnexa exists which may produce or aggravate the mental affection, a careful examination, under an anæsthetic if necessary, should be made.

(3) That in the investigation of criminal acts committed by women, either during the menopause or while the menstrual function is either active or suppressed, due weight should be given to the influence exerted by its irregularity or abeyance on the mind of the woman. In doing this, her previous history and temperament have to be considered.

(4) That the special dangers of the climacteric period and the symptoms indicative of threatening climacteric mania must be recollected. The principal of these are moroseness and depression of spirits, attacks of hysteria, occasional hallucinations of sight and hearing (especially of smell), suspicions with regard to relations, unjust dislikes, unfounded apprehensions of some great crime committed or injury inflicted on them, suicidal tendencies. Here again examination of the pelvic viscera is justifiable.

(5) That in operations on the female generative organs there is a greater predisposition to mental disturbance than after other operative procedures, but the post-operative insanity is generally of a temporary nature.

(6) That women who have been previously insane are predisposed to a relapse by the development of disease in their sexual organs, and especially to such temporary recurrence of insanity after operation on these organs.

(7) In order to anticipate suicidal impulse, and the commission of crime, the disordered mental symptoms exhibited at the menstrual epochs and at the climacteric should be carefully noted, and if the discharge or the cessation of the sexual function be attended by evidence of disease in the sexual organs, an examination of these should be made, when, if gross lesions be detected, operation should be resorted to.

A RARE FORM OF ULCERATION IN THE FEMALE URETHRA. (a)

By RICHARD DANCER PUREFOY, M.D.Dub., F.R.C.S.I.,

Master of the Rotunda Hospital; Obstetrical Surgeon to the Adelaide Hospital, &c., &c.

THE close resemblance in aspect and clinical history between some forms of chronic syphilitic disease and others of a malignant nature, has long been recognised—indeed, sometimes the effect of treatment by drugs must be observed before the differential diagnosis can be safely established. Especially is this observable in regions where cutaneous and mucous structures coalesce, and hence the external female genitals, as might be expected, furnish some of the best illustrations of this fact. A young woman, who recently was under treatment in the Gynaecological Wing of the Rotunda Hospital, complained of pain and soreness in the vagina, and on examination the following conditions were observed:—The greater labia were of normal size and healthy. On the inner surface of the left nymphæ a circular excavation existed, the edges sharp-cut and overhanging; the base, white, cicatricial tissue. The entrance of the vaginal canal was closed by a morbid growth, with nodulated surface of a deep red colour, which, on close examination, proves to be an out-grow h hanging from the edge of an enormously dilated urethra; indeed, the lower third of this passage was so widened and distorted, that considerable difficulty was experienced in passing a catheter into the bladder. Strange to say, the patient, in spite of this, did not suffer from incontinence of urine. In the vestibule and adjoining parts an indolent shallow ulceration was observed, alternating with patches of white cicatricial tissue marking its former course. Dr. Purefoy said: In the writings of the late Dr. West I had long ago observed some records of cases so closely, if not absolutely identical, with the one under consideration that I do not hesitate to quote some of his remarks. He says:—"The affection has come six times under my observation—twice in married women, who acknowledge to having suffered from venereal disease; and four times in women of unchaste life, one of whom was at the time suffering from a secondary syphilitic eruption. In each instance the patient alleged that she had either been aware of the ulceration or had for some time suffered from painful and difficult micturition. Twice the disease was associated with excrescences from the mucous membrane of the urethra. The ulceration appears to begin at the orifice of the urethra, extending thence inwards towards the bladder, producing in its course a great widening of the canal and a patulous condition of its orifice, so that the finger tip can easily enter it, while the surface is the seat of large indolent granulations which secrete a small quantity of muco-purulent fluid, are not generally very tender to touch, but highly sensitive to the passage of urine."

I have met with this ulceration independently of any other disease in these parts, but also in cases where previous ulceration had destroyed the clitoris and the nymphæ, and have seen it associated with unhealthy ulceration about the posterior commissure of the labia and the entrance to the vulva, as also with those small condylomatous growths about the vulva which one often meets with in cases of vascular tumour of the urethra, and these latter, indeed, are far more commonly present than absent. When the disease has advanced far, or has been of long standing, the cellular tissue beneath the urethra

(a) Read before the Royal Academy of Medicine in Ireland, January 5th, 1900

usually becomes considerably thickened, and I have seen the lower wall of it represented by a dense cartilaginous substance, not unlike one of the lips of a hypertrophied and partially procident cervix uteri, while on two occasions I have been able to carry my finger along the whole length of the canal into the bladder. Even when not far advanced this disease causes difficulty in the retention or actual incontinence of urine, while, when it has extended along the whole canal, and left its aperture permanently patulous, the sufferer may be afflicted with complete incontinence. In one such case I have seen, the patient, *æt.* 22, had suffered from the infirmity for many months. She was afforded some slight relief and comfort by wearing a pessary, which, by pressing against the urethra, partly closed it. In another such case the ulcerated canal was so widely open that two fingers could be easily passed into the bladder. In its earlier stages this distressing affection admits of some amelioration by local measures—the application, for instance, of oxide of zinc in the form of ointment, or lotion with liquor plumbi; and, even in the advanced stage, attended with widening of the urethra, the use of strong nitric acid, or the actual cautery, may bring about such cicatrization and attendant contraction of the diseased parts that control of the bladder may be regained. Some facts in the history of my patient, as well as some scaly patches on the face and neck, afforded such presumptive evidence of a syphilitic taint that I prescribed for her a combination of bichloride of mercury and iron in mixture, and its use was followed by marked improvement, though I cannot be sure of its permanence. In many points these cases bear a close resemblance to that formidable disease of the female genitals first described in 1849 by M. Hugnier, and to which he gave the name “*lupus hypertrophicus, or perforans*.” This affection is very rare; I have myself only once seen it, and medical literature does not afford records of more than about forty cases in all. In the admirable “*Memoirs on Diseases of Women*,” by Dr. M’Clintock, will be found excellent illustrations of some of them. Whatever views we entertain as to their pathological history, they serve, I think, to enforce the remark with which I began this short communication.

FIVE CASES OF ANGINA PECTORIS.

By DR. SALOMON,
of Berlin.

I HAVE recently had under observation five well-marked cases of angina pectoris, which present several points of interest. The symptoms were alike in all. At first a painful sensation was complained of behind the upper part of the sternum, so severe as to compel the patient to relinquish whatever he was doing, and seek support. After a variable interval the distressing sensation was repeated. There were no asthmatic symptoms in any of the cases. In the course of a few weeks the pain began to radiate to the left arm, and soon the patient found it almost impossible to go upstairs. Finally even gentle movements, such as undressing and getting into bed, started the pain. Some months later an attack came on of the most agonising pain, taking the breath away with a feeling as if death were imminent. The duration of such attacks was from ten minutes to several hours. The attacks usually recurred at shorter and shorter intervals. One patient, however, had only a single attack and another did not have a well-marked attack at all.

Case I. died suddenly during an attack; he had suffered from syphilis.

Case II. was that of a gentleman, *æt.* 58, who was

intemperate, and was suspected of having had syphilis. The attack came on at constantly diminishing intervals day and night. Morphia only gave ephemeral relief. Ultimately maniacal attacks came on and he died.

Case III. was that of a man, *æt.* 53; the attacks were probably started by influenza. There was no history. He also died, and sclerosis of the coronary arteries was found after death.

The next two patients recovered. A man towards the end of the fifties was accustomed to immoderate exertion, both physical and mental. He had one attack which lasted 24 hours. This was four years ago. He gradually lost the sternal pain on walking, and became able to take long walks and climb hills without inconvenience. Case V., a patient also in the fifties, was a neurasthenic in consequence of venereal excesses. He also recovered after several attacks of moderate severity, and has been well for two years.

Sclerosis is the recognised cause of the disease, but a good deal depends on its situation and degree. We meet with angina, dependent on ischæmia of the heart, a condition which obtains in aortic regurgitation and stenosis. Sée never recognised a pseudo-angina of nervous origin.

Sée’s views and his treatment by the iodide was fully recognised in Germany. Previously treatment was purely hygieno-dietetic. For the attacks themselves we had ether, chloroform, amyl nitrate, nitroglycerine, morphia subcutaneously, &c. But recovery cannot be effected by these medicaments, and although the attacks may thereby be shortened or ameliorated, death was still the usual sequel. It was only with the introduction of the iodides by Huchard in 1883 that a serious attempt was made to prolong life. Iodines are supposed to strengthen the cardiac muscle and to dilate the blood vessels, and Huchard reported a number of striking recoveries under treatment with the iodine salts, and he assumed that they had a resolvent effect on the arterio-sclerotic process. According to Sée, however, the vascular lesion continued unchanged, as evidenced by numerous autopsies. He concluded that the beneficial effect was due merely to the action of the medication on the circulation as a whole.

Among German authors Vierordt, from being an opponent, became a warm advocate of the iodide treatment, and at the Medical Congress of 1897 he reported a number of really remarkable successes. Treatment should be continued for at least a year, and should be resumed at intervals afterwards. Vierordt believed in a positive curative effect of the circulating iodine, particularly on the walls of the blood vessels.

Personally, I do not believe that iodine can do any good in genuine cases of ordinary angina. There is an angina with a neurasthenic base, which in its symptomatology and its prognosis differs from that of coronary angina, and in my experience patients with coronary angina die, while those with neurasthenic angina get better.

The treatment is not affected by the distinction, for iodine along with the hygieno-dietetic treatment must always occupy the first place.

AMBROISE PARÉ AND HIS TIMES.

By J. GRANT ANDREW, M.B., C.M.,
Assistant-Surgeon to the Victoria Infirmary, Glasgow.

THE following sketch of the great French surgeon, Paré, is based on material derived from the classical monograph of Malgaigne and the admirable biographical study of Mr. Stephen Paget. Paré was born in 1510 and died in 1590, so that his life was

practically co-extensive with the century. Paré was surgeon-in-ordinary to four French kings, and among the more notable of Paré's contemporaries were Luther and Erasmus, Calvin and Knox, Shakespeare and Rabelais, Raphael and Titian, Montaigne, Paracelsus, Servetus, Sylvius, and Vesalius. During the Dark Ages the ban of the Church on the dissection of the human body had arrested pathological research and development in surgery, with the result that the great mediæval surgeons can be counted on one hand. The rediscovery of the literature of the ancients, which partly caused and partly followed the Renaissance and the revolt against prescriptive authority, imparted new life to the study of surgery. Paracelsus, with all his charlatanry, was a beneficent iconoclast, and Paré, on the experimental side, was the great pioneer of sinner methods of operative surgery and regimen. Paré was born at Bourg-Hersent, in Marne, his father being, according to one account, "coffretier," or maker of wooden chests; according to another, valet-de-chambre and barber to the Seigneur de Laval. Ambroise had a sister, Catherine, who married Gaspard Martin, a master barber-surgeon of Paris. His education was irregular and elementary. He says, quaintly:—"I desire not to arrogate to myself that I have read Galen either in Greek or Latin, for it did not please God to be so gracious to my youth that it should be instructed in the one tongue or the other."

An opportunity which Ambroise had of "assisting" an eminent surgeon from Paris, who came to the village to perform an operation, fired him to try his fortune in Paris, and since his brother-in-law was a barber-surgeon there Paré set himself to learn surgery. There is no record of the circumstances of his student life beyond the fact that, while still unqualified, he was lucky enough to get an appointment at the Hôtel Dieu as house surgeon where he continued three years, accumulating a vast store of data for future use, one of his teachers being the great anatomist, Sylvius. After leaving the hospital Paré did not settle down to spend his life in a barber-surgeon's shop for a practice to grow up slowly. He had too much ambition and energy for that. It was a stormy age of frequent wars, and Paré resolved to live a double life—with the army in times of war, at Paris in the intervals of peace. Accordingly we find him present at every campaign until 1569, when he ceased to wander, and lived quietly, but industriously, at home, one of the most familiar and best-beloved citizens of Paris. He died about Christmas, 1590, just after Henri IV. had raised the siege of Paris, which, in respect of the frightful suffering which it caused, has been compared to the siege of Jerusalem by the Romans. We know nothing of the manner of Paré's death.

War has always had its horrors, but in this scientific age it is difficult to conceive of the monstrous inhumanities rife in Paré's times. We owe his description of these, and of the more humane methods of treatment which he introduced, to the mere accident that he was attacked in his old age by a preposterous Dean of the Faculty of Medicine, who asserted that Paré's use of the ligature after an amputation was vastly inferior to the old-established use of the cautery. "The book was an idiotic appeal to authority and tradition; the very thing that Paracelsus would have loved to burn. But it has an everlasting merit, inasmuch as it drew from Paré his 'Apologie et Traicte contenant les Voyages faicts en divers Lieux.' This work, which is remarkable for rich humour, pungent wit, and shrewd observation of the facts of disease, and of men and affairs, gives an account of Paré's campaigning experiences, and of the lessons he drew from them, and casts many instructive sidelights on the manner and customs of medical and surgical practice in the sixteenth

century. The thesis of his defence being the superiority of ligaturing and soothing treatment for hæmorrhage and gunshot wounds, &c., to the orthodox methods of the actual cautery and boiling oil. He naturally gives much attention to the miseries of the wounded under the prevailing system. One passage will serve as a sample of his quality:—"The soldiers within the castle, seeing our men come on them with great fury, did all they could to defend themselves, and killed and wounded many of our soldiers with pikes, arquebuses, and stones, whereby the surgeons had all their work cut out for them. . . . I had read in John de Vigo

. . . that wounds made by firearms partake of venenosity, by reason of the powder, and for their cure he bids you to cauterise them with oil of elders, scalding hot, mixed with a little treacle; and, to make no mistake before I would use the said oil, knowing this was to bring great pain to the patient, I asked first, before I applied it, what the other surgeons did for the first dressing, which was to put the said oil, boiling well, into the wounds, with tents and setons: wherefore I took courage to do as they did. At last my oil ran short, and I was forced instead thereof to apply a digestive made of the yolks of eggs, and turpentine. In the night I could not sleep in quiet, fearing some default in not cauterising, that I should find the wounded to whom I had not used the said oil dead from the poison of their wounds, which made me rise very early to visit them, where, beyond my expectation, I found that those to whom I had applied my digestive medicament had but little pain, and their wounds without inflammation or swelling, having rested fairly all night; the others, to whom the boiling oil was used, I found feverish, with great pain and swelling about the edges of their wounds. Then I resolved never more to burn thus cruelly poor men with gunshot wounds." Paré then relates how he paid court to a surgeon of Turin to discover his secret and sovereign balm for gunshot wounds. He succeeded, and was much gratified to find the recipe, which was to boil in oil of lilies young whelps just born and earthworms prepared with Venetian turpentine, "was like that which I had obtained by chance."

One of the cures upon which Paré dwells with venial pride will have a peculiar interest for pharmacists as an example of the sixteenth-century drugging. By command of the king, Paré attended M. d'Auret, a Flemish nobleman, who was almost moribund with a suppurating gunshot wound in the thigh. Paré very naively remarks that when he saw that the patient was so ill he was very sorry that he had come, for his own reputation. In consultation with the staff of physicians and surgeons who had been treating d'Auret for seven months, Paré prescribed a course of treatment which is only partly indicated in the following extracts:—"For the bedsores . . . a fresh soft bed, with clean shirt and sheets. For the swelling and coldness of the limb hot bricks, sprinkled with a decoction of nerval herbs in wine and vinegar, and to the feet an earthenware bottle filled with the decoction. The thigh and the whole of the leg to be fomented with a decoction made of sage, thyme, lavender, flowers of chamomile and melilot, red roses boiled in white wine, with a drying powder made of oak-ashes and a little vinegar and half a-handful of salt. For the bedsores a large plaster made of the desiccative red ointment and of Ung. Committissae equal parts. . . And for the strengthening of the heart a refrigerant of oil of water lilies, ointment of roses, and a little saffron dissolved in rose-vinegar and treacle, spread on a piece of red cloth. For the syncope . . . good nourishment full of juices, as raw eggs, plums stewed in wine and vinegar, broth of the meat of the great (stock) pot, the white meat of

fowls, partridges' wings minced small, and other roast meats easy to digest, as veal, kid, pigeons, partridges, thrushes, and the like, with sauce of orange, verjuice, sorrel, sharp pomegranates; or he may have them boiled with good herbs, as lettuce, purslane, chicory, buglass, marigold, and the like. At night he can take barley-water, with juice of sorrel and of water-lilies, of each two ounces, with four or five grains of opium, and the four cold seeds crushed, of each half an ounce. . . . For the great pain in his head his hair must be cut and his head rubbed with rose vinegar just warm. . . . also a forehead cloth of oil of roses and waterlilies and poppies, and a little opium and rose vinegar, with a little camphor, all wrapped in a handkerchief, to be held some time to his nose. . . . And we must make artificial rain, pouring water from some high place into a cauldron, that he may hear the sound of it, by which means sleep shall be provoked in him. . . . For the knee, ointment of mallows and oil of lilies, and a little *eau-de-vie* and a wrapping of black wool with the grease left in it." It is evident from this example that Paré possessed one of the chief secrets of success in medical practice—he was a master of minutia; but while, probably, some of the details were introduced for the sake of their dramatic or moral effect, Paré did not omit the essentials, which were the opening of the abscess and the administration of opium, along with careful dieting. The use of opium in an age which esteemed powdered unicorn's horn a panacea and crushed mummy "the sovereignest thing on earth for an inward bruise" is significant of Paré's bias towards more rational modes of treatment. The last book that Paré wrote was in denunciation of the craze for mummy. "Ambroise will have none of it, 'flesh of decomposed, cadaverous, dead bodies.' He has never seen it to do anything but give the patient a pain inside and make him sick. The ancient Jews, Egyptians, and Chaldees never dreamed of embalming their dead to be eaten by Christians. . . . It smells so bad that fishermen use it for bait. . . . Nobody is sure what it really is. Some people believe that mummy is made and manufactured in our own France, and that they take the bodies, by night, off the gallows, eviscerate them, dry them in an oven, dip them in pitch, and sell them for good, true mummy, saying they bought them of Portuguese merchants, who brought them from Egypt." He then tells the story of a friend of his who visited a storehouse of mummies, owned by a Jew, at Alexandria. Asked if the bodies had been brought from the sepulchres of the ancients. "The Jew fell a-laughing and mocked at this . . . saying that it was not four years since he had prepared all these bodies himself, thirty or forty, and they were the bodies of slaves and such-like people. He did not care whence they came, nor what they died of, nor whether they were young or old, male or female, provided he got them, and nobody could tell who they were once they were embalmed, and he marvelled greatly that the Christians were so greedy to eat the bodies of the dead."

Considering the activity and vicissitudes of his life, Paré was a prolific writer. His writings, according to the custom of his time, range over a wide variety of subjects in anatomy, surgery, medicine, obstetrics, State medicine, pathology, pharmacy, natural history, and demonology. Many of his treatises brought him into violent conflict with the Faculty of Medicine, which controlled the whole profession at that time. The interests of the three leading branches of applied medicine were represented by (1) the corporation of barber-surgeons, which had worked its way up from the position of a craft to a quasi-professional footing; (2) the confraternity of surgeons; and (3) the Faculty of Medicine, which stood for the physician

proper. These institutions were perpetually engaged in a sort of triangular duel. Paré began his career as a member of the corporation of barber-surgeons. He underwent two examinations, but it is not clear whether they were two separate examinations or whether Paré failed the first time he went up. When Paré became distinguished by his skill and his Court appointment, he naturally wished for a better professional status, and he sought to enter the confraternity of surgeons, and they were so eager to have him that they plunged into a labyrinth of irregularities, and, although they made a pretence of ploughing him, he was admitted soon after, and it was understood that the examination was merely formal. His enemies of the Faculty never allowed him to forget that he had been smuggled into the fold; but the great grievance which that body had against him was that he wrote his books in the vernacular, and even when he got some of them turned into Latin they were not propitiated, but Paré held his own against them, and sometimes outflanked all their forces.

While Paré's works contain much sound doctrine on the subjects with which they deal, they also reveal the limitations of his age. "He had no knowledge of the circulation of the blood or of the absorbent system, no anæsthetics, no antiseptics, no bacteriology; his understanding of the nervous system was not in advance of his times, and he had neither microscope, nor stethoscope, nor thermometer." Paré believed that the stars influenced the course of disease, that the plague came of itself by the Divine will, apart from Nature, as a punishment for the sins of the people, although he endeavoured to trace its natural causation, that maggots in wounds and many other living things were generated spontaneously. He believed in the devil, evil spirits, sorcery, and witchcraft, and in the power of saints to cure disease. He had a firm faith in the royal touch for the king's evil. As an offset to these superstitions, we find that "some of his operations were curiously modern. He understood and practised what we now call massage, he had a good way of producing local anæsthesia, he was opposed to immoderate bleeding, he knew the value of rest and silence for his patients."

In his private character Paré presents many engaging aspects. He was sociable, peace-loving, humane, and the friend of the poor. In some respects he was very like his illustrious successor, John Hunter, whose maxim "Why think? Why not experiment?" was the keynote of Paré's method. "They both of them began life in the country, they saw something of war, and wrote on gunshot wounds. . . . They spent the money lavishly when it came, they were great lovers of animals and their ways. . . . They loved the collecting of specimens, dissecting them, demonstrating them. . . . But there are two points of special likeness between them—first, the constant appeal to experience; next, the love of questioning, comparing notes, getting to know the results obtained by other men. Paré rashly predicted that the surgical advances of his time had left little for posterity to improve upon, and now his own methods are antiquated, his theories all wrong, his books are the forgotten treasures of a few great libraries. Our methods, our explanations, will also be superseded; our books, many of them, will not even be treasured. He has kept his hold for three centuries by force of character, and that alone."

THE Queen has sent through Lady Addington a beautiful quilt to the Buckingham Nursing Home. The article is not only valuable, but it is also interesting from the fact that it was worked by Her Majesty.

Transactions of Societies.

CLINICAL SOCIETY OF LONDON.

MEETING HELD FRIDAY, JANUARY 26TH, 1900.

SIR R. DOUGLAS POWELL, Bt., President, in the Chair.

MR. J. HUTCHINSON, JUNR., read a paper on

RESECTION OF GANGRENOUS INTESTINE IN CASES OF HERNIA.

He related two cases of successful primary resection of small intestine during herniotomy, both operations being performed by simple enterorrhaphy without mechanical aids. One was a woman with a strangulated femoral hernia on whom he had operated in 1893, removing five inches of damaged gut, she was in good health six years later. The second case was a man with strangulated inguinal hernia, in this it was necessary to excise ten inches of intestine, this was done by Maunsell's method—that is one in which an artificial intussusception was made. The patient made a perfect recovery, but died three years later from ulcerative colitis, and the specimen was fortunately obtained for Mr. Hutchinson by Mr. H. L. Barnard. It was shown at the meeting, and proved that there had not been the slightest narrowing at the site of the resection. Mr. Hutchinson remarked that it was probably the general impression that the use of Murphy's button had rendered resection of intestine not only quicker, but safer. To test this belief he had collected from hospital records (including all the cases he had himself operated on both with and without this apparatus), fifteen examples of primary resection for gangrenous gut performed with Murphy's button, and sixteen cases in which suturing alone was employed. Of the former only one (seven per cent.) had recovered, of the latter six (forty per cent.). This was a very striking comparison, but besides this the fatal cases treated by suturing alone had lived on an average twice as long as those in which Murphy's button had been used; in other words, they had given so much more promise of survival. Three out of the ten fatal cases of simple suturing would probably have recovered but for accidental complications (multiple strictures of small intestine, obstruction of intestine by an omental band, and tuberculous phthisis causing constant cough). Moreover, the post-mortem records showed, on the whole, better union of the divided ends after suturing than after the use of Murphy's button. The latter was apt to cause acute congestion by its bulk, its weight was also a disadvantage, and even should the patient recover it was probable that a stricture might result. At any rate, the openings made by operations with Murphy's button in gastro-jejunostomy sometimes showed a marked tendency to contract. The greater time required for the accurate performance of suturing did not appear to be of much practical importance—it had probably been a little exaggerated. The after-shock had not been dangerous in his experience. Whilst primary resection of [gangrenous, perforated, or irretrievably damaged intestine in a hernia must always be attended with high mortality, it yet offers the best chance of recovery. Of eleven such cases treated by other so-called conservative methods—formation of an artificial anus, &c.—every one had died. This agrees with the results previously brought forward by Mr. Kendal Franks, Mr. C. B. Lockwood, and other surgeons. Turning to the details of the operations, in performing resection it was of great importance to excise enough of the damaged intestine so that the sutures might be placed in healthy tissues, and it was nearly always advisable to do it through a median abdominal wound. Special care had to be taken with the mesenteric ends of the two ends, for leakage most readily occurred at this point. Maunsell's method was probably one of the best to employ. If the intestine could be emptied and made to contract this would favour sound union and tend to prevent infection of the stitch apertures by the septic contents. It was probable that the administration of an aperient immediately after the operation would lead to

better results than in the past. The author had operated on 140 cases of strangulated hernia with a total mortality of 25 per cent. Sixty-five were inguinal herniæ, of which fifty-four recovered; fifty-four were femoral, and of these forty recovered; whilst twenty-one were umbilical, and of these twelve recovered: taking all the fatal cases together, thirty-four deaths in all, 25 per cent. The great majority were due to the gangrenous or acutely inflamed condition of the intestine and omentum at the time of operation. Five of ten fatal cases were possibly due to the employment of too conservative methods.

Mr. BARKER said he much preferred primary resection to the use of Murphy's button, which he thought was merely a phase in the evolution of this class of operation. He pointed out that the amount of intestine removed was a matter of no great importance, the essential element of success being that the suture should be applied to healthy gut, the walls whereof had not been injured by distension. He related three cases of intestinal suture of his own. In one the button dragged the intestine into a kink and caused death. In two others he sutured with excellent results without even a bad symptom, but he was careful to resect far away from the seat of the original lesion.

Mr. HOWARD MARSH remarked that excision of the intestine for gangrenous intestine was not nearly as dangerous an operation as was generally supposed, but he agreed that it was necessary to remove the intestine from a sufficient range so that no untrustworthy part was included in the suture.

Mr. CHARTERS SYMONS observed that the statistics of the operation would no doubt improve, because in future they would probably operate in a much larger proportion of cases. The great difficulty in his opinion was to empty the intestine, thus preventing continuance of the symptoms from subsequent paralysis of the bowel. He expressed himself in favour of direct suture, and concurred in the views expressed adverse to the use of Murphy's button.

Mr. HUTCHINSON, junr., in reply, said he had used sutures of fine silk going through all the coats. He remarked on the fact that they found no adhesions of any sort of that part of the intestine or on the corresponding part of the peritoneum, the scar being absolutely smooth. He was unable to suggest any novel method of emptying the bowel, and remarked that if some means of doing so could be devised the operation would be greatly simplified. He, too, had been struck with the superiority of the direct suture in gastro-jejunostomy, the cases not exhibiting any tendency to contraction at all.

MR. A. PEARCE GOULD read a case of

BULLET WOUND OF THE ABDOMEN, WITH FOUR WOUNDS OF THE SMALL INTESTINE AND TWO OF THE MESENTERY: OPERATION: RECOVERY.

The patient was a young German, æt. 20, who was accidentally shot with a small revolver on the evening of October 30th, 1899. A doctor who was called to him at once found him in great pain and administered an hypodermic injection of morphia, and then took him on to the Middlesex Hospital where he was seen by Mr. Pearce Gould about an hour after the accident. The wound in the abdomen was 2 ins. below the navel and 1 in. to the left of the middle line. There was still some pain; the respiration was easy and the abdomen moved freely; pulse 96. The liver dulness was not obliterated, no dulness in either flank. No paralysis; 6 ozs. of clear normal urine were drawn off by catheter. Under an anæsthetic the wound was explored and found to extend into the peritoneal cavity. This was freely opened and blood flowed out from it, but neither gas nor intestinal contents were observed. The intestine was examined, and four wounds apparently in the jejunum were found, three of these were perforating, the other involved the serous and muscular coats only. There was no visible escape of intestinal matter. These wounds were closed with Halsted's sutures of sterilised silk, and two wounds of the mesentery which were close by were also sutured. No other lesion was found. The peritoneal cavity was cleansed, the bowel returned and the abdominal wound closed. The man made an uninterrupted recovery, and left the hospital.

well, on December 4th. The bullet was found lying deep in his left buttock and was left alone. In commenting on this case Mr. Pearce Gould drew attention to the following points:—1. The multiple lesions produced by a single bullet. 2. The absence of symptoms of the granular lesions. 3. The necessity for exploration, even in spite of the absence of all symptoms, to determine whether the wound was perforative, whether any viscus or large vessel was injured and, if so, to treat them. He emphasised the importance of the hypodermic injection of morphia immediately after the accident, both in relieving pain and shock, and in controlling the movements of the intestine and so lessening the chance of fouling of the peritoneum with germ-laden intestinal contents. The case illustrated the necessity for careful and thorough exploration of the abdomen (by operation) in all cases of perforating wound and severe contusion of the abdominal wall.

The PRESIDENT remarked that the case was one of great interest to both physicians and surgeons. Although the administration of opium and morphia had, not without reason, been discarded in these cases, he pointed out that it was one thing to give them while the diagnosis had yet to be made, and quite another to administer them after the diagnosis had been made clear. With a bullet wound through the abdomen they might take it for granted that the abdomen had been injured, so that there was not the same objection to the use of morphia in such cases in view of the relief to suffering which it procured, especially on the battlefield. They were invaluable in perforations and the like. He suggested that the absence of shock in the author's case was largely due to the patient's being under the influence of morphia.

Mr. BARKER commented on the fact that some patients with severe abdominal injuries suffered severely from shock, while others scarcely suffered at all. He remarked that the results in these operations must greatly depend on the time they were taken in hand after the injury. If seen at once every surgeon he supposed would explore, but if not seen until after a lapse of time doubts might be entertained. He thought that small bullets with high velocity might pass through the abdomen without inflicting necessarily fatal injury. He concurred in the view that opium was at present left too much in the background.

Mr. HOWARD MARSH referred to two cases of his own, one that of a boy who had been run over by a cab who exhibited no symptoms of shock, &c., and this induced him to abstain from operating. The lad died next day, and then he was found to have sustained a ruptured colon. In the other case a gentleman while hunting was thrown on to a heap of stone, and was severely shaken. Nevertheless, he remounted and rode home, went the next day to London, and it was only on returning home that he fell into a state of collapse and died, when it was found that he had sustained an injury of the superior mesenteric artery causing gangrene of the bowel. He insisted on the value of saline injections to overcome shock in these cases.

Mr. NEWTON PITT called attention to the fact that veterinary surgeons were the habit of puncturing distended intestine through the abdominal wall with a large trocar usually without any disastrous results. He recalled the report of a case which had recently appeared in which a soldier had received a bullet right through the abdomen in which nothing was done, yet the man recovered. If an exploratory operation could be done under favourable circumstances he would do it, but not otherwise.

Mr. GOULD, in reply, said the patient was only partially under the influence of morphia. He suggested that the difference in the amount of shock must be due to some physical cause. In his own case it was the small intestine and the mesentery close to the intestine that were injured, so that the deeper nervous plexuses escaped injury. Possibly the absence of shock was due to this fact. He agreed that saline injection were often useful, but in this case the condition of the patient did not appear to call for it. On the whole he thought that experience of puncturing the intestine in man was un-

favourable to the practice. He admitted that if they operated in every case they would alight on a certain proportion in which there was no perforation of intestine but as against these there were the cases in which grave injury was unaccompanied by serious symptoms, and he thought the balance was in favour of routine exploration.

ROYAL ACADEMY OF MEDICINE IN IRELAND SECTION OF OBSTETRICS.

MEETING HELD FRIDAY, JANUARY 5TH, 1900.

The President, Dr. A. V. MACAN, in the Chair.

SPECIMENS EXHIBITED.

DR. PUREFOY.—A case of ectopic gestation removed by vaginal coeliotomy, with microscopical section showing chorionic villi.

MULTILOCULAR OVARIAN TUMOUR.

Dr. ALFRED SMITH showed a multilocular ovarian tumour which he removed from a patient aged thirty-five. The patient was seized with severe abdominal pain and acute distension, with much distress. Examination under ether demonstrated uterus free, and a tumour the size of a full-term uterus, which would not come down to the pelvis; no pedicle could be made out. Diagnosis doubtful. Operation revealed a tumour distended with blood; pedicle acutely twisted. No adhesion had formed. Recovery.

SYPHILITIC PLACENTA.

Dr. HEARD, of Monkstown, exhibited a specimen of above.

Dr. PUREFOY insisted on the interest of the association of albuminuria with a state of health which could only be removed by the use of mercury, and the albuminuria made that fraught with danger.

Dr. SMITH thought the condition of the intima of the arteries must be known before they could determine whether the placenta was syphilitic or not.

Dr. JELLETT asked was the quantity of albumen large, and had the woman suffered during pregnancy or before it?

On the motion of Dr. MONTGOMERY the specimen was referred to the Committee of Reference for decision as to whether it was syphilitic or not.

Dr. GLENN exhibited a specimen of intraligamentous myoma removed by coeliotomy.

DECIDUOMA MALIGNUM.

Dr. W. J. SMYLY, in a paper on deciduoma malignum, reviewed the literature of the subject, pointing out that observers were now almost unanimous in believing that this was a disease sufficiently distinct to merit separate consideration. They also agreed as to its clinical features, pathological appearances, and treatment; also as to its connection with pregnancy, and differed only as to their views concerning its histogenesis. Having reviewed the various theories upon this subject, he said that in the present state of our knowledge it was impossible to determine which view was correct, but he inclined to Veit's opinion, that the disease was a sarcoma, modified by pregnancy. He also described a case which had come under his own observation. The patient, a pluripara, was delivered of a hydatiform mole in December, 1898. She had repeated hæmorrhages until May 10th, when she had so profuse a hæmorrhage that she was reduced to a condition of profound anæmia. The uterus was dilated, and a quantity of material resembling placenta removed, which, on microscopic examination, proved to be deciduoma malignum. Putrefaction and septic fever followed, with pulmonary symptoms and empyema preceding radical measures. She lingered two months and then died. There was no post-mortem examination. Dr. Smyly showed the microscopic specimens at the Edinburgh meeting of the British Medical Association, when they were pronounced by Dr. Sanger to be typical examples of the disease which he had described.

Dr. PUREFOY said he had never felt the tissue of the

uterine wall in such a condition of utter degradation and softening as it was in this case. It felt like brown paper. The mole structure removed on the first occasion was of a nature not commonly seen in these cases. He thought it was mixed fleshy and hydatiform mole. Scattered through it were distinct vesicles, evidence of vesicular degeneration being also present.

Dr. SMITH said he was inclined to regard it as an ordinary sarcoma influenced by pregnancy. He knew some eminent pathologists who thought it an ordinary sarcoma. The whole literature of the subject was embodied in Dr. Smyly's excellent paper.

The PRESIDENT said there was one case not mentioned by Dr. Smyly—i.e., Pick's case, in which he found the metastasis of the ordinary hydatid mole not to be malignant. Pick considers that the fetal structures are only accidental, and they may even form embolisms without being malignant. Opposed to Veit's opinion (which most people would agree with) was that which regarded it as carcinoma of the outer layers of the epithelium covering the villi.

Dr. SMYLY replying, said the point about metastasis in cases of hydatiform mole was one of extreme practical importance, because anyone who had not learned otherwise would think that when metastasis occurred the case was hopeless. But the metastasis might not be malignant; a woman might have benign meta-stasis in her lungs and recover after operation. Of course, if there were malignant metastases the case would be perfectly hopeless.

A BARE FORM OF ULCERATION IN THE FEMALE URETHRA.

Dr. PUREFOY read a paper on this subject which will be found on page 106.

In the discussion that followed, Dr. SMITH asked what was the difference between this condition and prolapse of the mucous membrane of the urethra?

The PRESIDENT said he specially asked the question as to whether the orifice of the urethra was in the centre, because the same idea had occurred to him as to Dr. Smith. The ulceration seemed to be very much like the ulceration that took place in prolapse.

Dr. PUREFOY, in reply, said that if the President and Dr. Smith had seen the case they would not put forward the opinion that it was prolapse. It had no character in common with that condition. Some of the tissue was whitish, and of almost cartilaginous hardness. The outline of the urethral canal was perfectly distinct. The tissue was entirely different from the ordinary mucous lining of the urethra, and was associated with and continuous with cicatricial tissue.

The Section then adjourned.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.

MEETING HELD THURSDAY, JANUARY 18TH, 1900.

The President, Dr. BURGESS, in the Chair.

Dr. ARTHUR HALL introduced a case showing the remains of vaccination pustules on the "chapped hands" of a girl, *et. 15*, who had not previously been vaccinated. She had nursed a recently vaccinated baby about a month previously.

Dr. VINCENT showed a specimen of adenoma of the kidney from a patient who had died of apoplexy.

Dr. RISELEY read the notes of a case of

ABSCESS OF THE BRAIN FOLLOWING INJURY OF THE EYELID.

The patient was a boy, *et. 1*, who was admitted to the Royal Hospital, Sheffield, on October 20th, suffering from an abscess in left upper eyelid. The lid was very prominent, dull red and glazed looking, and there was a small wound with sloughy edges and distinct fluctuation. Three weeks previously the child had run a rusty sharp-pointed file-maker's tool into the eyelid for about an inch. The wound did well for a time and then began to swell up. The lid was incised transversely on admission, an excessive amount of pus escaped, and on introducing finger bare bone was felt. The wound was plugged with iodoform gauze. Temperature remained

subnormal and child apparently did well till the second night, when meningitis set in, temperature rose to 100, and the patient died within 12 hours of onset of symptoms. Towards the last the eyeball could be seen apparently quite normal. There was escape of cerebro-spinal fluid from wound. Post-mortem: Fracture of orbital surface of frontal bone. Lymph covering brain on upper and under surfaces. An abscess on under surface of frontal lobe size of large walnut, communicating through the fracture with wound of lid. The abscess cavity contained a little pus and some iodoform crystals and was lined by pyogenic membrane.

Dr. N. BARDSWELL read a report on eight months' trial of

THE SANATORIUM TREATMENT OF PHTHISIS

at the Sheffield Royal Infirmary. Accommodation had been made for twenty patients, but the conditions under which the trial had been made were disadvantageous. In the grounds hammock chairs for the patients and a revolving shelter had been erected for accommodation in bad weather. Routine treatment had been for the most part modelled on that followed at Nordrach. Apyrexial cases spent the whole day in the grounds, those with pyrexia lay by open windows, the wards being well aired throughout the night. Three chief meals were given, viz., at 6 a.m., 12.30 and 7 p.m., extra butter, milk, and eggs being added to the infirmary "full diet," the diet being modified for individual cases when necessary. Carefully regulated walking exercise was allowed in cases with a temperature never above 100.2. Pulmonary gymnastics were also employed in convalescing cases, systematic massage replacing exercise in bad cases. Practically, no medicines were given except bitter tonics, and cod-liver oil and malt. Temperature was taken every four hours in the axilla, the pulse and respiration were recorded night and morning. The sputum was measured and recorded every day in drachms, the weight was recorded weekly. In all thirty patients had been treated, eighteen of them being still in the Infirmary. The cases were unselected. By far the best results had been obtained in patients with a small amount of active disease, and good general condition. Out of seventeen such cases five had been nearly cured, and returned to suitable work, and the rest were very much improved in every respect. Cases with extensive, active disease, and severe constitutional disturbance, and those with phthisis laryngea had done badly, half of them dying, and the rest improving in the summer to remain stationary or to relapse in the winter. As far as Sheffield Infirmary was concerned nearly all the patients improved considerably under treatment from April to September, but during the winter months all cases, except those with small lesions, and those who were well advanced towards convalescence, either ceased to improve or became worse.

BRITISH LARYNGOLOGICAL, RHINOLOGICAL, AND OTOLOGICAL ASSOCIATION.

MEETING HELD FRIDAY, JANUARY 12th, 1900.

Dr. BARCLAY BARON, President, in the Chair.

THE PRESIDENT showed an obscure nasopharyngeal case. A middle-aged man, after having a discharge of pus and blood from the nasopharynx and deafness for several months, began to suffer from severe paroxysmal pain in the right side of the head, becoming gradually worse and more extensive. Later, there was numbness of the skin of the same side of the face. Examination revealed a small, hard, circumscribed swelling with a smooth surface in the upper part of the nasopharynx.

After a few remarks by Mr. Mayo Collier, Mr. WYATT WINGRAVE said that he could detect a hard swelling apparently on the internal pterygoid plate, which was suggestive of a new growth.

Mr. J. BARK (Liverpool) related a case of painful spasm of the muscles on one side of the face, cured by removal of a nasopharyngeal polypus.

Mr. WYATT WINGRAVE showed a case of lupus of the

fauces, with extensive ulceration extending down to the larynx, causing much destruction of tissue.

Dr. R. Woods (Dublin), expressed a doubt as to the case being lupus, and advised specific treatment. Mr. Mayo Collier gave reasons for similar views, and Mr. Wyatt Wingrave replied.

Dr. DUNDAS GRANT showed (1) a case of emphysema of the orbit in a labouring man due to blowing the nose. (2) A case of laryngitis secondary to rhinitis. (3) A case of bridge-like synchiae between the septum and the inferior turbinal body without ascertainable cause. (4) A case of lupus of the inferior turbinal.

Dr. FURNESS POTTER showed. (1) A woman, æt. 47, with postnasal growths which he considered to be persistent adenoids. After giving his reasons for this view he mentioned other cases of postnasal growth in adults which had proved to be malignant. (2) A case of a growth on each ventricular band in a man, æt. 39. (3) A case of extensive papillomatous growth of the vocal chords.

Mr. ATTWOOD THORNE showed for Dr. WILLIAM HILL a case of stammering in a youth.

Dr. DENNIS VINRACE thought that, the cause being neurotic the treatment indicated was careful tuition with avoidance of attempts at conversation when excited, and attention to the general health.

Mr. MAYO COLLIER advised the removal of the adenoids present, and exercise for the thickened palate.

Mr. ST. GEORGE REID observed that in some cases where the velum was sluggish and pendulous, and articulation indistinct it was advantageous to remove a small piece of its posterior edge.

Dr. BROWN KELLY (Glasgow) read a paper upon

EPISTAXIS FROM THE ETHMOIDAL VEINS.

He reported several cases of severe epistaxis in which the stream of blood had been traced to the septum above the anterior end of the middle turbinal. He showed that the vessels ruptured were probably the anterior ethmoidal veins, and that these are closely connected with the intra cranial circulation. The absence of valves in the veins and the pressure in the longitudinal sinus would allow of a profuse flow in a backward direction. Hæmorrhage from this source are easily checked by packing gauze between the middle turbinal and the septum anteriorly.

Mr. J. BARK (Liverpool) observed that recurrent epistaxis in adults usually occurred in the position indicated by Dr. Kelly, and that a small plug inserted between the middle turbinal and the septum was effectual and caused little discomfort.

Dr. R. Woods alluded to the constitutional treatment of such cases, supplemental to local measures. Mr. Mayo Collier and the President also joined in the discussion.

Dr. R. Woods (Dublin) showed a skiagraph of a foreign body in the œsophagus of a child, which was successfully removed.

PARIS, January 27th, 1900.

RHYTHMIC TRACTIONS OF THE TONGUE,

At the Académie de Médecine M. Laborde spoke on the mechanism of the respiratory reflex and tractions of the tongue. If upon the living animal, he said, moderately anesthetised, the trunks of the superior laryngeal nerves were excited, a more or less intense agitation with incoherent respiratory efforts would be observed ending, if the irritation continued, in the arrest of the respiratory movements. On the other hand, by exciting the central end of the pneumogastric nerves in an animal placed experimentally in a state of asphyxia, or of apparent death, a return of the respiratory movements was witnessed, so that under this new condition the intervention of the irritating cause provoked and brought back the functional activity instead of producing its suspension

or arrest. He had applied from that fact a double application of mechanical methods of traction of the tongue, namely, the rhythmical or intermittent traction when it was a question of awakening and of maintaining the suspended respiratory reflex; continued traction when it was necessary to obtain the arrest of a morbid hyperactivity such as spasm of the diaphragm constituting hiccough.

M. Pinard said that when a child was apparently still-born he introduced the tube of Chaussier into the larynx after having removed all the mucus from the region and practised artificial respiration. Immediately the heart began to beat more frequently, and in successful cases vermicular movements were observed in the diaphragm, and finally the first inspiration, followed quickly by others thus establishing definitely the function. Consequently, and without wishing to detract anything from the experiments of his colleague, he was of opinion that it was the air alone which acted upon the heart first and the respiration afterwards.

M. Laborde answered that he was far from wishing to ignore the efficacy of insufflation of air into the trachea in children apparently still-born, but it was, nevertheless, true that in individuals profoundly asphyxiated, rhythmical tractions of the tongue succeeded where insufflation of air failed. It was for that reason, and also relying on his personal researches, that he thought he was authorised in saying that the first method was more efficacious than the second, and was of more easy application. He did not condemn, however, insufflation of air, and thought it should be employed concurrently with traction of the tongue when possible.

ABSCESS OF THE LIVER.

M. Lucas communicated a case of abscess of the liver in a man who had lived in Algeria ten years, where he had contracted the disease which terminated in abscess. On his entry into the hospital the patient was in a miserably cachectic condition, fever, sweats, &c. Suppuration of the liver being suspected an exploratory trocar was passed in at a selected point giving issue to 500 grammes of pus. After having resected the ninth and tenth ribs behind, the speaker incised the abscess and withdrew nearly three pints of matter. The seat of the suppuration was then washed out with oxygenated water, two drains were placed *à demeure* and the wound closed. At present the patient is as well as might be expected, and although he was operated on rather late, there was a good chance of definite recovery. As to the instrument chosen for incising the liver Dr. Lucas said that he always used the thermo-cautery instead of the knife; the former was more tedious, but the loss of blood was reduced to a minimum.

BERLIN, January 27th, 1900.

THE PROPHYLATIC TREATMENT OF PUERPERAL FEVER.

Prof. DÖDERLEIN in a paper in the *Therap. Monatsch.* strongly advises the use of india-rubber gloves in cases where manual interference is necessary as well as the usual means for insuring absolute cleanliness. Treatment has not, he says, gone hand in hand with bacterial knowledge, nor has it advanced equally with prophylaxis, but it has distinctly advanced with the aid of

bacterial knowledge. In all cases of puerperal infection the infective germs can be demonstrated in the interior of the uterus. The variation in the clinical symptoms depends on the variety of bacteria and their poisonous qualities. One thing, however, is constant, the temperature and the cardiac activity form the first and most exact indication of the condition. These objective signs render possible a timely causal method of treatment.

If one proceeds on the assumption that the primary disease is in the uterus, by the time these symptoms above named show themselves, the bacteria will already have invaded the tissues, the lymph tracts, the glands and blood vessels, where they can be further followed up. There appears, therefore, a prospect of fighting the infection only when the uterus can be properly cleared out and disinfected in the first stages of the disease. Opinions, however, are not at one as to the best way of doing this. We scarcely know what remedies are effective, but one thing we do know and that is that on account of their dangerous qualities we must abstain from such highly poisonous antiseptic solutions as sublimate and carbolic acid. Ahlfeld had recently recommended alcohol, and the writer had made use of a 96 per cent. solution.

As regards antistreptococcus serum, his experience, contrary to that of many, had been favourable, and, for the future, he would not omit its employment in any case of streptococcus infection. The remedy was, however, of use only against infection with streptococci, so long as no deleterious consequences of a general or local kind had taken place.

As regarded symptomatic treatment, in his opinion, the free employment of antipyrin was the most trustworthy. In certain rare cases total extirpation of the uterus recommended by Schultze was justifiable and successful. In illustration of this he reports two cases in which he performed the operation with success.

At the last meeting of the Free Society of Surgeons, Hr. Weber read a note on

SUBPHRENIC ABSCESSSES.

Of 600 cases of perityphlitis seen in the Moabit Hospital there was suppuration in 300 and in nine the abscess was subphrenic. In six cases the vermiform appendix was situated under the liver, the cæcum dragged upwards. He thought the fact of importance as regarded the origin of subphrenic abscesses. Besides the recognised ways along the colon and behind the peritoneum, there was a third way in which pus could reach the subphrenic space.

The pleura was implicated in all the cases, in seven there was empyema, and in two dry fibrinous pleurisy. In all the cases but one the pus was intraperitoneal. The speaker was of opinion that subphrenic abscesses could be avoided if extensive incisions were made so that the whole field of disease could be brought into view. The abscess was opened in most cases through the pleura; in those where the pleura was not affected after the costal pleura had been sutured to the diaphragm.

Hr. Sonnenburg followed with a paper on

THE TREATMENT OF CIRCUMSCRIBED ABSCESSSES OF THE PERITONEAL CAVITY.

Riedel, of Jena, had recently published a work on this subject, in which he laid down the principle that the abdomen should be opened at once as soon as fever set in

and a palpable tumour was present; he went carefully over the abdomen, held back the intestines with gauze, opened the abscess under the protection of compresses, and carefully wiped away every trace of pus; he then closed the abdomen in layers, but leaving the skin unsutured, and allowing a strip of gauze leading from the abscess cavity to the outside to remain in the angle of the wound.

The speaker did not think the procedure worth being copied; it was quite certain that the healthy peritoneum could bear much more than was formerly suspected, and that only irritated peritoneum was incapable of resisting infection. The question only was the peritoneum near the abscess to be looked upon as healthy. In the majority of recent cases he should say no; an inflammatory irritability was here set up by toxins, and a few bacteria would be enough to bring about suppurative peritonitis. It seemed therefore better to wait until the stage of irritation was past and firm adhesions had formed. Then it was advisable to get into the abscess as directly as possible, sparing the adhesions, clearing the cavity, and then closing the wound. It was here there was danger of ventral hernia, but it was safer than to close the wound, and if hernia did occur it would be operated on at a later stage without danger.

Hr. Karewski had lately had two subphrenic abscesses not of perityphlitic origin, one had its origin in osteomyelitis of the 11th and 12th ribs. The other case was that of a child who was run over, and was admitted with symptoms of general peritonitis. Under expectant treatment the condition improved, but in four weeks it got worse again and a subphrenic abscess developed which was opened through the pleura. In the abscess the whole of the spleen was found broken up and mixed with blood. The pus was sterile. Recovery took place.

Hr. Körte during the last 10 years had treated 35 cases of subphrenic abscess, of which 23 recovered; 16 started in the vermiform appendix, of which 11 got well. The inflammation in the appendix could run itself out, as was shown by some sections where nothing but residue of an old inflammation could be found in the part. He did not believe toxins could set up peritonitis; in all cases of peritonitis examined bacteria were found in the pus. A palpable tumour in a case of suppuration in the abdomen was a good sign, and indicated that adhesions had formed, but in itself it was not an indication for immediate operation, but rather for further waiting unless the condition called for immediate interference.

Hr. Londner had been led to the conclusion to attack all intraperitoneal abscesses, he was convinced that the peritoneum could take care of minute traces of secretion. His results had been so good that he saw no reason to alter his methods of treatment.

Hr. Sonnenburg explained that toxins could set up fibrinous peritonitis, but not the purulent form.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, January 27th, 1900.

MEDICAL DISCUSSION AND PAPERS IN LAY JOURNALS.
At the first meeting of the "Gesellschaft der Aerzte"

for 1900 the president, Prof. Chrobak, had a large number of invited guests, among whom was His Excellency, Von Hartel, Secretary of State, &c., whom he warmly greeted. In opening the session he said there was one thing that pained him deeply, and had often been condemned as unseemly in our profession which he hoped the members of this institution would endeavour to eradicate, viz., the publishing of medical subjects in lay papers. This was sadly to be deplored, but if individual members would assist him, he thought this degradation could be averted, as the blame lay in their own ranks, and not in the public.

He further added that he was asked by the Minister of Justice to give a categorical answer to the following questions, which he would read to the meeting:—(1) Do you consider the the Berne Convention with the Paris additions of any use to Austrian authors in literature, art, and photography; also what are the objections? (2) Should these branches be combined, or should any one receive preference to another? (3) Would the interests of the author, publisher and public be equally served by their union, or would this injure education? These questions were relegated to a committee for answer.

INJURY TO KIDNEYS AND BLADDER.

Weinlechner next showed a number of interesting cases, such as tabetic swelling at the knee-joint, with genu valgum; spontaneous fracture of the neck of the femur with hyperostosis; dermoid in buccal cavity. A young man, æt. 27, who fell from a scaffold and tore the right kidney; fever ensued, after which he operated removing the injured organ, with perfect recovery and urine elimination of 1,890 grammes, equalling 63·1 ounces.

Another case of a similar nature was that of a boy who fell from a tree, tearing the bladder, from which the urine passed into the rectum; at the same time, paresis of the detrusor vesicæ, sphincter ani, and both extremities were produced. He performed *sectio alta*, sewed the torn bladder and bowel, since when the continence of the urine has been entire, with an improvement in the paresis of the detrusor and sphincter ani muscles.

MEDICAL EXAMINATIONS.

The new regulations of the medical faculty have now been published by the Minister for Education which have excited a wave of criticism. Exner read a long paper to the "Gesellschaft" which was loudly applauded. Albert asked if this meeting had no power in the arrangement of these subjects, or was its province simply confined to debating them.

To his mind the whole examination was now confined to cramming the youth with a number of scientific facts without an opportunity of proving them. Supplementary theory for practice was surely a mistake. "Drill" and science was once the watchword of medicine, but theory without practice was now sufficient. The subjects were further postponed for discussion.

TRACHOMA.

At the "Doctoren Collegium" Hans Adler discussed the present treatment of trachoma, in a long paper, commencing with the history of the disease down to the bacterial research of which he said there were now 18 microbes assumed in the transmission of the disease. These imperfect results left diagnosis and therapy

equally empirical as the follicular catarrh was closely associated with trachoma though entirely distinct.

The present day treatment was always commenced by the prophylactic precaution of preventing transmission, viz., washing well with antiseptic fluids, to which too much importance cannot be attached. The treatment may properly be divided into three categories: (1) medicaments, (2) mechanical, (3) operative medicines. From early times silver, copper, and belladonna have been the sovereign drugs which are replaced by sublimate, 1 in 20,000 to 1 in 100, ichthyol, iodoform, kreolin, iodide of potassium, iodine in combination, tannin, boracic acid, quinine, antipyrin, carbolic acid, pyocetanin, petroleum, and 95 per cent. alcohol.

The mechanical treatment was extensive. Keinig's consisted in rubbing $\frac{1}{2}$ per 1,000 of a sublimate solution into the eye-lid with a piece of cotton wool. Massage has been practised with great success. The spray is often of service. The galvano-cautery is most effectual in the out-patients' department, allowing eight days' pause; this destroys all the granulations. Electrolysis is very painful, and with Johnston's instrument gruesome.

The surgical treatment surpasses all the others for variety. The first will remove all granules with the knife; another will do it by means of a metal pencil acting on each follicle; another will do it with a suitable brush; another by scarification or combined with a brush; another by excoriate with pincettes; another by syneeing and using rolling pincettes. The latter in proper hands has given good results. Kuhnt's expressor is an instrument with two plates and pincettes attached.

To remove the subsequent pannus, Wecker's jequirity method may be adopted, although stubborn cases may require the galvano-cautery.

In the discussion that followed, Mittler asked the usual practice adopted in Hungary?

Adler said there were two hospitals for such cases in Hungary under the direction of Prof. Feuer. Every case discovered is removed to hospital, and the home disinfected. No particular form of treatment is set down as a rule, but each assistant is allowed discretion.

The Operating Theatres.

ST. MARY'S HOSPITAL.

POPLITEAL ANEURYSM.—Mr. EDMUND OWEN operated on a case of popliteal aneurysm in a young man, a cabman. Mr. Owen remarked that it had probably been started by some severe strain upon the artery as the man was dragging his cab out of the coach-house. The aneurysm was sacculated, and he said he proposed to tie the popliteal artery in the upper part of the space; but on proceeding to do this there seemed to be so little promise of room between the upper part of the aneurysm and the opening in the adductor magnus, that the idea was reluctantly abandoned, and the vessel was tied at the apex of Scarpa's triangle with an aseptic silk ligature. Mr. Owen pointed out that the great advantage of tying the popliteal itself was that the risk of recurrence of pulsation in the sac was diminished, as well as that of gangrene of the foot, and that it was certainly unfortunate that the

inches of the artery in this case between the top of the popliteal space and the apex of Scarpa's triangle should have been unavailable in establishing collateral circulation.

BARKER'S OPERATION FOR TRANSVERSE FRACTURE OF THE PATELLA.—The same surgeon operated on a case of transverse fracture of the patella, the result of violent muscular contraction, the man trying to save himself from falling. The fracture had happened about five days previously, and the joint contained a considerable amount of dark blood, which was squeezed out through a small incision at the side of the patella. Mr. Owen then passed a large curved needle upwards through the ligamentum patellæ and in front of the trochlear surface of the femur and out through the quadriceps extensor. A thick silver wire was passed through the eye and the needle withdrawn. The unarmed needle was again inserted through the lower skin-wound, and being thrust up in front of the knee-cap was made to draw down the upper end of the wire. The halves of the patella were then brought close together in the loop of the wire and were so fixed by twisting up the wire and cutting off the ends. Mr. Owen described the operation he had performed as Barker's method, and said that he personally had, after considerable experience of it, every reason to speak well of it.

INGUINAL COLOTOMY.—The same surgeon performed an inguinal colotomy on an oldish man with advanced carcinoma of the rectum. The man had been examined under an anæsthetic by the class in the previous week, when it was thought that the malignant growth was too extended and too firmly fixed for the patient to be subjected to Kraske's operation. Mr. Owen specially pointed out that it was not necessary to bring up the peritoneum and stitch it to the skin, so as to line the wound with it; that the serous coat of the sigmoid flexure was as well able to fix itself by plastic exudation to the cut surfaces of the abdominal muscles and skin as to an opposed peritoneal surface. As there was no distension of the bowel, it was decided to delay opening it for several days, until the knuckle of intestine had become securely fixed in its new position.

KING'S COLLEGE HOSPITAL.

PYLOROPLASTY.—Mr. A. CARLESS operated on a girl, æt. 22, who had been suffering for some years from gastric symptoms suggestive of ulcer. Two years back he had opened the abdomen, explored the stomach both from without and within, and had found nothing amiss, although as the result of the operation the symptoms of gastric irritability disappeared. The improvement was maintained for ten months, but six months ago she began to suffer once more from the old troubles. Four months before the present operation she had been admitted to hospital for two weeks, but in spite of careful dieting she remained unimproved. She then went out and continued since then much in the same condition, being able to retain bread and milk, and Benger's food sometimes, but nothing more solid. On re-admission she was very thin; there was no tenderness in the epigastrium, although she complained of pain in that region after taking food. An incision was made partly to the right of the middle line and parallel to the scar of the former incision which had healed perfectly and had left no sign of hernial protrusion. On opening the peritoneum it was at once seen that there were

no adhesions connected with the stomach, and, in fact, the site of the former incision into the viscus was a little doubtful. A longitudinal incision was made into the organ about two inches from the pylorus and midway between the greater and lesser curvatures. On introducing the finger it was at once evident that the pylorus was contracted, the opening just admitting the tip of the index finger although on pressure it could be passed through the contraction. The stenosis was very limited in its extent, and Mr. Carless, therefore, proceeded to perform pyloroplasty, dividing the stricture in a longitudinal axis and stitching the wound up transversely. A double row of sutures was used, one for the mucous membrane and one for the serous and muscular coats. The first wound in the stomach was closed in a similar manner and the abdominal incision brought together with buried silk stitches after the peritoneal cavity had been filled as full as possible with warm sterilised salt solution. Mr. Carless stated that this was a typical case in which to perform pyloroplasty, the absence of adhesions, and the limited extent of the stenosis were the essential indications for such a proceeding. The operation, he said, is devised with the idea of increasing the lumen of the pyloric orifice and has been found to fulfil the expectations formed of it most admirably, the food being subsequently able to escape from the stomach without obstruction. The risk associated with the operation is very slight. Mr. Carless also drew attention to the importance of endeavouring to prevent the formation of adhesions after such an operation, and said that it was partly for this purpose that he had filled the abdomen with salt solution before closing it; a second object that is attained by this procedure, he added, is the diminution of shock, partly by the effect of the warm lotion on the sympathetic centres, partly by the rapid absorption of the fluid into the circulation. Too little attention had been in the past, he thought, directed to the prevention of the formation of adhesions after laparotomy, and consequently obstructions and strangulation by bands were only too common sequelæ. Raw surfaces uncovered by peritoneum must not be left, and surgeons and gynecologists, he pointed out, must learn to cover up all such wounds in some way or other, possibly by omental grafts, if they desired to protect their patients from the above-mentioned untoward consequences.

Society for Relief of Widows and Orphans of Medical Men.

At the quarterly court of this society, held on January 10th, Mr. Christopher Heath, V.P., in the chair, two new members were elected, and the death of Sir James Paget, president, and Mr. Gimson, a director, reported. Mr. Christopher Heath, from the chair, proposed the following resolution:—"The quarterly court of directors of the Society for Relief of Widows and Orphans of Medical Men desires to record its great regret at the death of Sir James Paget, Bart., the president of the society, who has for many years taken the greatest interest in the society's welfare and until recently has regularly taken the chair at the meetings of the court." There were fresh applications for grants, and the death of a widow was announced who had received since January, 1875, £1,333 10s. from the funds. It was resolved that £1,205 10s. be distributed among the 48 widows, 11 orphans, and the 6 recipients from the Copeland Fund. The Christmas present, £531, had been given on December 18th. The expenses of the quarter amounted to £74 14s. 6d. The nomination of a president was postponed to the April court.

“SALUS POPULI SUPREMA LEX.”

WEDNESDAY, JANUARY 31, 1900.

**WORKMEN'S COMPENSATION AD
ABSURDUM.**

THE principle that grants compensation to workmen injured in the course of their employment is recognised almost universally as just and beneficent. It has been adopted by the legislature and reduced to concrete form in a recent Act that marks a considerable step in the adjustment of the complex and often conflicting interests existing between capital and labour. That legislation on the question is still imperfect must be admitted by all who agree with the justice of the main proposition that a workman injured by circumstances arising directly out of his occupation is entitled to compensation from his employer. The working of an Act, however, is the only satisfactory way of finding out its imperfections, and we venture to say that the decision in a case tried within the last few weeks under the Employers' Liability Act affords a startling and even from some points of view illogical application of that particular law. Briefly stated, the facts of the case were that a collier somewhere in the North of England, scratched his hand when at work, and subsequently suffered from a septic wound, which was followed in turn by chronic septicæmia. There appears to have been no contention that the original injury was anything more serious than a superficial abrasion, such as must occur every day in the week in every factory and coal pit throughout the length and breadth of the United Kingdom. The workman brought an action against the employer, and obtained heavy damages. This decision is of the utmost importance to the future of the Compensation Acts, and we trust that there will be some appeal so as to raise the question of its validity. The main objection to the verdict that will suggest itself at once to the medical mind

is that the septicæmic condition was merely a remote and accidental complication of the accident, a septic state not essentially connected with the workman's occupation. If a scratch were to be the invariable antecedent either to blood poisoning, or to an action for compensation, then the employment of labour by capital would be seriously hampered in many industrial occupations. There is no employment conceivable in which the servant would not be exposed at some time or other to the risk of an abrasion of the skin, such as a scratch by a pin or a splinter of wood. Every such wound of the cutaneous surface, however trifling in itself, is liable to inoculation at the time or to subsequent invasion by the micro-organisms that give rise to various septic conditions of the system. Therefore, every employment is liable to give rise to septic blood conditions owing to trifling scratches incurred by workmen in the course of their occupation. Fortunately, such serious results from such trifling antecedents are rare, and in that rarity lies the key to the situation. As every medical man knows, these general septic invasions of the system following surface wounds are nearly always confined to persons who are broken down in constitution and unhealthy from various causes. In the case above alluded to the employers have most likely been called upon to pay heavy damages the demand for which would never have arisen had the plaintiff been endowed with tolerably sound bodily health, whereby he would have been enabled to resist the microbial invasion of his skin. From the decision of the judge it follows that employers must be prepared to accept risks not only as regards accidents arising out of the nature of their trade or calling but other and more remote results, such as septicæmia following trivial injuries not essential to their particular trade or calling and, moreover, entirely dependent on the bodily state of health of any workman who may be injured in that way. It may be well to recall the fact that in insurance cases remote blood poisoning is held sufficient ground for a claim. At the same time such a principle applied to vaccination would make a vaccinator responsible for septic invasion of a wound weeks after the operation. It seems to us that the chain of reasoning is conceivably open to question in a Court of Appeal. Whether that higher jurisdiction would go so far as to reverse the judgment to which we have called attention is another matter. Were domestic servants dealt with under the Employers' Liability Act, as they sooner or later will probably be included, an endless crop of litigation would be raised in the way of whitlows and “housemaid's knees,” both of which injuries may be fairly described as arising directly out of the nature of the employment. Going back to the broader aspects of the matter it is interesting to speculate upon what evidence the Court arrived at its decision in the septicæmic case. With every sympathy for the circumstances of the workman it is impossible to shut one's eyes to the fact that the employer also has his rights and immunities. To interpret the Liability Acts so as to exact damages from an employer on account of septicæmia following a scratched finger tends, we

repeat, to reduce the whole special legislation concerned more or less to an *ad absurdum* phase. By allowing the pendulum to swing too far in favour of the workman his cause may be permanently damaged. It is to be hoped, therefore, that, in the interests both of capital and labour, an appeal will be lodged forthwith in this important case. If that desirable course be not pursued then we would urge some member of Parliament to lose no time in bringing the matter before the House of Commons. Meantime, it would be well for all employers of labour, and for all journals interested in trade questions to inform themselves of the medical aspects of the matter in a more thorough and detailed fashion than has been possible within the limits of the present article.

INTESTINAL SURGERY.

NOT so many years ago the surgery of the intestines was one of the least promising departments of abdominal work, but although it still presents technical difficulties peculiarly its own we are in a fair way to see these overcome, at any rate in great measure. A few years ago the introduction of Murphy's button and Mayo Robson's bobbin was greeted with a chorus of welcome by surgeons who hoped to find in these undoubtedly ingenious contrivances a means of obviating certain technical difficulties, but subsequent experience has steadily discredited their use and skilled opinion is slowly but surely veering round in favour of direct suture by improved methods. This is hardly the place for us to dilate upon the drawbacks attending the use of these mechanical contrivances; suffice it to say that surgical opinion, as represented by speakers at the various medical societies appears to be adverse to their use except in very special circumstances. There is one condition of success in cases of injury of the intestine which, we fear, must always obtain, viz., the obligation of dealing with them within a short time of the receipt of the injury. That obligation is inherent to the anatomical circumstances, and must always militate against a great increase in the proportion of successful interventions. Surgeons have learned that the removal of comparatively large portions of intestine is not a matter *per se* of much importance while it is all important to make sure that the parts sutured shall be healthy and uninjured. The great bugbear of the surgeon in dealing with wounded intestine is the risk of the continuance of the symptoms after operation in consequence of temporary paralysis of the intestine resulting from distension. This, indeed, is one of the grave problems with which he is still confronted. Puncture of the distended intestine by the aid of a small trocar has not given encouraging results, although in the hands of veterinary surgeons it is reported to be commonly employed without an undue proportion of untoward results. Possibly, this immunity from disaster, if authentic, may be due to the fact that the procedure is had recourse to in animals which are suffering solely from distension, obviously a very different state of things

from that of the patient who is the victim of strangulated hernia, or whose intestines have been severely contused by a passing cab. However that may be, surgeons are still on the look-out for a means of emptying the intestines without entailing additional risk to the patient. It may turn out that resection of the damaged intestine, if not too extensive, is the only way out of the difficulty if only by reason of the fact that, as has been shown, the damaged intestinal wall allows the passage of the, when out of bounds, lethal coli bacillus against which it is scarcely possible to guard. There is one detail of importance which has been brought to the front in recent debates, viz., the desirability, or otherwise, of giving opium and morphia in these cases. Of late years it has been the fashion to decry their use on the ground that they mask the symptoms, and that they enhance the paresis of the intestine. Now it is open to question whether it is not a positive advantage to quiet the peristaltic movements of the injured gut for a time, if only to secure the physiological rest of which it stands in need. The masking of the symptoms is only of importance, while the diagnosis is uncertain but once this has been established there does not seem to be any valid reason for withholding the relief of suffering and shock which opium and its derivatives are capable of affording. We are glad to see that several surgeons have raised a protest against the indiscriminate refusal to sanction their use, and we may hope ere long to be favoured with a code of rules as to when these drugs may be given with advantage. One curious feature which merits passing notice is the curious difference in the degree of shock and pain exhibited by the victims of severe intestinal injury. In some, possibly in most instances, pain and shock are prominent symptoms, but there are plenty of instances on record in which grave wounds of the intestine, as indeed of other viscera, have not been followed by what the surgeon would consider adequate symptoms. This is a point to bear in mind in considering the propriety of performing an exploratory operation as a matter of routine. If the surgeon relies too much on these indications of injury he will find, in a certain proportion of cases, that life has been sacrificed for want of timely intervention. If he adopt the routine method of exploration on the other hand he will discover that his intervention was unnecessary. On the whole, however, a safe plan is to explore in every case seen within a short time of the injury. In respect of the cases seen later on the absence of grave symptoms may be taken to indicate that no serious injury of contained viscera has been inflicted.

INFLUENZA AND THE THERMOGENETIC CENTRE IN THE BASE OF THE BRAIN.

A NUMBER of the cases observed during the present influenza epidemic have exhibited no further symptoms than those of high temperature, unaccompanied by headache, arthritic pains, or any signs of catarrh of other organs. The attacks of pyrexia were generally of very sudden onset, and rapid rise of the

body temperature, and were either single or relapsing. In one case known to us in a physician 106 degs. was reached in a few hours; about double the time taken in the rise sufficing to bring the thermometer down to the normal again. In another instance, although the patient was kept in bed throughout, eighteen hours, almost precisely, elapsed between the onset of the pyrexia, three hours seeing the temperature rise to 104 degs. or 105 degs., then for nine or ten hours violent sweating and a fall to normal, at which it remained until the eighteenth hour saw it rise again. These paroxysms were unaccompanied by any other symptoms save restlessness while the temperature was rising, or by sweating as it fell. The appetite was good, the breathing quiet, the pulse no quicker than the rise in temperature called for. In this case quinine proved a specific; alkalies, antipyrin *et omne hoc genus* failing. As a rule, quinine has little effect on influenzal attacks, although useful beforehand as a preventive; in fact, it seems that where catarrhal processes have been induced by the poison it fails to benefit. It is difficult to understand how the *materies morbi* can be present in such strength as to cause intense derangement of the thermotaxic mechanism without affecting other organs of the body, and apparently other parts of the central nervous system. The influenzal poison certainly picks out the weakest part in each organism but when it confines itself to the temperature centres (and to do this a supply of bacilli and toxin must be present in the circulating fluids), it closely resembles ague, the more closely in that under such circumstances it yields to the action of quinine. The organism of influenza, therefore, would seem to be more catholic in its tastes than that of malaria, finding congenial sites in various tissues in which to set up changes, which vary with the parts affected, and result in inflammations, mild or intense; disorder of function, up to apparent insane actions on the part of individual nerve centres. When the result is pyrexia simply and is only during one attack, antipyrin, &c., suffices; when periodic, quinine arrests the process: when complicated with inflammatory action, these and other remedies in suitable combination are called for. There is no sense in laying down, anyhow, as to what one drug or method is *the* way to treat influenzal attacks; as the nature of the seizures varies so profoundly, so must our treatment. The only general law which may be possibly invariably true is, stimulate and feed as much as may be.

Notes on Current Topics.

Street Mud in Winter.

THE part played by mud in the hidden and various ways of disease-production will doubtless be one day laid bare by some curious apostle of science. Meanwhile there are certain points about mud that are clear to the man in the street. Its distribution by the splash of passing vehicles covers a much wider

field than folk usually recognise. Spots of mud thus projected may often be seen adhering to house-fronts at a height of several feet above the top of the ground-floor windows. Dry mud, be it remembered, is on the way to become dust, to be blown hither and thither with its host of microbes good, bad, and indifferent. "The bacteriology of street mud" who will undertake that investigation, laborious, well-nigh boundless, fascinating, complexly baffling, and yet fraught with vast potentialities for the good of man. The average citizen, however, knows little and cares less for the bugbears of bacteriology; he is more concerned for the safety of his clean collar, the polish of his silk hat, the sheen of his shoes, and the untarnished splendour of his raiment beneath the splatterings of a muddy day in the City. Where the mud comes from is a mystery in the case of smooth impermeable pavements. It is certainly greatly lessened in amount when asphalt, concrete, or wooden roadways replace the time-honoured macadam. Judging from the signs of the times it seems likely that in a not distant future sanitary authorities will learn to take a deep interest in the matter of City mud in relation to the public health.

The Value of Anti-Vaccinationist Evidence.

WANT of candour is a common and conspicuous failing on the part of those of our countrymen who are inspired with the stubborn spirit of "faddism." The anti-vaccinationists are of that ilk and the history and literature of their faction abundantly illustrate the methods of suppression of facts and of fallacious reasoning dear to narrow and ill-trained minds. A certain number of newspapers pander to the follies of the anti-vaccinationist, just as they would to any other untruth or absurdity that would be likely to swell their circulation. This section of the Press paraded a recent death at Ashton-under-Lyne as that of a "Victim to Vaccination." A sober consideration of the facts, however, must convince everyone that vaccination had no more to do with the death than an ordinary scratch or pin-prick. A child, five months old, was vaccinated with the glycerinated calf lymph of the Local Government Board on December 19th. The operation was conducted by the public vaccinator, who afterwards applied an antiseptic dressing. On January 3rd, erysipelas appeared, and the child died shortly afterwards. The facts that disconnect the erysipelas from the vaccination are: 1, the use of glycerinated calf-lymph, which is sterile of all but vaccine organisms; 2, the antiseptic precautions taken by the vaccinator; 3, the interval of fifteen days between the inoculation and the appearance of the erysipelas, pointing to a late inoculation of the wound, probably by neglect and carelessness of the parents. The jury recognised the true state of affairs in their verdict which was to the effect that the child had died from exhaustion, consequent upon erysipelas, supervening upon vaccination, but how the erysipelas was contracted there was no evidence to show. The newspapers have made their own evidence.

Materia Medica on a Large Scale.

THE central administration of the hospitals of Paris is a large customer in the drug market, as might be imagined, but the figures in this year's estimates are nevertheless calculated to cause some astonishment. By way of purgatives, the annual consumption of castor oil reaches 1,900 kilogrammes, with 3,000 kilogrammes of Epsom salts, 1,600 of sulphate of soda, and 60 of senna leaves. It takes 30 kilogrammes of ipecacuanha root to get the patients to expectorate with ease, but 10 kilogrammes of male fern suffice to rid them of their intestinal parasites. Sedatives obtain a large share of patronage, bromide of potassium running to 1,200 kilogrammes, of sodium 150, of ammonium 60, and of strontium 10, along with a kilogramme of bromide of gold. Sulphurous baths are in great favour in France, but even so 40 tons of liver of sulphur is a tall order. Quinine has for years stood at four tons, and the number of empty cachets, a mode of administering medicaments greatly appreciated by French patients who are refractory to nauseous mixtures, reached the gigantic total of 800,000. The consumption of peptone rose last year from 80 to 100 kilogrammes, but pepsin fell from 40 to 10 kilogrammes, which looks as if that ferment had seen its best days. The consumption of kola also fell (250 to 200 kilogrammes), but this may be due in part to the more restricted use of so-called medicated wines, into the composition of which kola enters for a very large part. Among miscellaneous details we note 40 tons of liquorice and 1,600 kilogrammes of cherry-stalks. In the matter of cod-liver oil 16 tons ought to go a long way, and as much may be said of the 60 tons of glycerine and the 16 tons of vaseline. By way of conclusion we have 12 tons of boracic acid, 1,600 kilogrammes of corrosive sublimate, close upon 10 tons of carbolic acid, half a ton of permanganate of potassium and 24,000 litres of camphorated alcohol. A detail not without interest is an increase in the quantity of chloroform consumed, from 1,200 to 1,600 kilogrammes, while ether remains stationary at 1,400 and cocaine at 12 kilogrammes. Not the least interesting feature of the materia medica budget is the uniformity which characterises the demand year by year. Evidently if there be such a thing as fashion in medicine it stops short at the threshold of the hospitals.

The Housing of the Poor Problem.

THE urgency of the question of the housing of the poor in our great cities is shown by the rapid phases in which the matter has been presented to the public. Local authorities throughout the kingdom have been aroused and many schemes adopted, not a few of them of a costly and complicated description. The ever-present difficulty is to rehouse near their former abode the population, displaced by the demolition of unhealthy areas, and by other public improvements. The latest departure of the London County Council involves an expenditure of about half-a-million. They have bought thirty-eight acres of land at Tooting for

£45,000. Upon the site thus acquired they propose to erect workmen's cottages under Part III. of the Housing of the Working Classes Act. In this way accommodation would be provided for 12,000 persons. One of the members of the Council pointed out that nine months had been consumed in buying a site to house 12,000 persons, but during that time the population of London had increased by 30,000. Before the houses were finished the population would have increased by 160,000. Fortunately, a fair proportion of the enormous annual addition does not belong to the class of society affected by the housing problem. Within the next fifteen or twenty years it seems likely that enormous sums will be expended under the Act in various parts of the country. The burden will fall on the already heavily taxed ratepayers, who will possibly be left to ponder to some purpose the why and wherefore of the exemption of ground landlords from the payment of rates.

A Plague Laboratory.

THE St. Petersburg Institute of Experimental Medicine has just completed the construction of a laboratory for the study of plague and the preparation of anti-plague serum which is probably unique of its kind. The building is situated within the fortress of Cronstadt, and is surrounded by water on all sides so that it is completely isolated. It is provided with stabling for twelve horses, and apartments for the staff and the assistants; there is even an isolation ward for the reception of any of the employes who may be unfortunate enough to contract the disease. It is self-lighted by electricity and communication with the mainland is secured by a small steam launch. No doubt the lamentable catastrophe at Vienna which startled the scientific world a few months since suggested these elaborate precautions. Such a laboratory is indeed as potentially dangerous in its way as a powder magazine, possibly even more so, because there still exists the theoretical risk of the conveyance of infection. It would, however, be difficult to suggest any further precaution short of condemning the staff to perpetual banishment on their island.

The Apothecaries' Society and the General Medical Council.

THE announcement that Sir Hugh R. Beevor, Bart., has been appointed representative of the Apothecaries' Society of London on the General Medical Council entails the disappearance from that body of a member, Mr. Brudenell Carter, whose individuality had of late been felt to be somewhat burdensome. Mr. Carter accepted the representation at a time when the Society required the services of an experienced and unflinching advocate, and he unquestionably fulfilled his task with much vigour and skill. Having steered the Society through the shoals and having assisted in securing it a fresh lease of existence under peculiarly favourable circumstances, Mr. Carter continued to represent that corporation in a way which was certainly not to the taste of the profession nor apparently to

that of his constituent body. Past master in sarcasm and invective, his caustic oratory was wasted when devoted to the discussion of the arid details of professional education, and was out of place when questions of medical policy were being debated. As member of the Penal Cases Committee, Mr. Carter succeeded, quite unnecessarily, in arousing deep-seated hostility all round, but whether this was the result of negligence or of indifference we are left in doubt. It must be admitted, on the other hand, that Mr. Carter not unfrequently imported into the debates an animation which is usually conspicuous by its absence, but we are not sure that the result was always to promote the urbanity of debate which ought always to characterise the proceedings of so august a body as the General Medical Council. Mr. Carter's career on the Council recalls to one's mind the adage that "though 'tis good to have a giant's strength, it is not good to use it as a giant."

Clergymen as Sanitarians.

THE Church Sanitary Association has done well to turn its attention to a matter which is deserving of much consideration, namely, that of inducing the clergy throughout the country to become the advocates of sanitation among their parishioners. Next to the medical practitioner the clergyman of the parish has generally the most influence in advising the poor to do that which is good in their own interests, and inasmuch as a great deal of what we regard as unhygienic habits arises from mere ignorance, it is obvious that the enlightenment of the poor upon such matters could readily be undertaken by the clergy were they willing to do so. For example, in many poor rural parishes much could be done by tactical advice by the clergy in the promotion of the observance of sanitary laws among their poor parishioners. The penalty of offending against hygienic and sanitary laws is generally exacted either in the form of sickness or death, and not only the individual but oftentimes, no doubt, the community would gain in cases where timely advice on sanitary matters given by the clergy were acted upon. The clergy might well devote some of their spare time to the administration of useful knowledge of this kind within their respective parishes.

Neglect of Dentistry in Medical Education.

IN our issue of January 3rd we commented upon the undeniable fact that, while the student is laden down with the minutiae of diseases which he will probably never see in a lifetime and is harried at his examinations on such subjects, he is sent out into practice without adequate teaching or testing on the subjects with which he has to deal, all day and every day, from the moment he enters into general practice. As illustrations, we instanced the passing of a catheter, the application of a leech, and the extraction of a tooth as procedures which are the very elements of a student's profession, but without a knowledge of which he may go into practice. The journal of the British Dental Association, in an endeavour to controvert this statement, affords us valuable

evidence of its accuracy. It says that at two London general hospitals (out of twelve to which schools are attached) "the student is able to receive the most careful instruction in such details as are likely to be of importance in general practice," and, furthermore, it believes that, "in one of these two hospitals each house surgeon acts, during his three months, as assistant to the dental surgeon." If the instruction thus indicated is, confessedly, all that London medical students can obtain outside of a special hospital, we apprehend that our case is proved. But we may remind our contemporary that, in medico educational matters, it is not enough to inform the student that he "is able" to obtain information in some particular subject unless he is made to produce such information at his examination, a requirement which is never thought of, yet we must assume that his inability to get a tooth out of its socket is amply compensated when he comes to earn his professional living, by his erudition in the domains of psychology, forensic medicine, and other such business-like and practical subjects.

The Case Against Hospital Isolation in Scarlet Fever.

WE have been favoured with a pamphlet with this title from the pen of Mr. Edward Dean Marriott, of Nottingham, which we have perused with more curiosity than interest. Compulsory isolation unquestionably has its drawbacks, and we had looked forward to an interesting, if unconvincing, disquisition in which, as is the manner of disquisitionists, the disadvantages would be heartfully marshalled in such a way as to throw a new light on this modern departure in municipal hygiene. Instead of that, we have a somewhat hysterical protest against compulsory segregation, couched in language which may be described as odd, in which serious argument is conspicuous by its absence. It would have been much more to the point if, instead of accusing the sanitary authorities of "fooling around" and "smashing up" the health of sundry of his little patients, the author had set himself the task of deducing such lessons as might legitimately be drawn from the admitted failure of the isolation system to stamp out this particular disease. The author sees in the steadily-increasing spread of scarlet fever a *consequence* of compulsory isolation in hospital, whereas most people capable of forming a dispassionate opinion would consider that the increase is in spite, and not on account, of this preventive measure. Fortunately, the greater incidence of the disease has been associated with a marked diminution in the proportional mortality, but the problem of providing accommodation for the huge number of cases must, for years to come, tax the resources of municipal authorities all over the country. Moreover, the author propounds no alternative means of dealing with these cases. He accuses practitioners of deliberately abstaining from notifying any cases after the first in a given household, on what grounds we know not. Are we, however, to understand him to advocate the abandonment of hospital isolation without any scheme to take its place? The

pamphlet appears to have been written solely for the purpose of influencing local electioneering politics, but we cannot imagine that the author's slipshod effusion will have the desired effect; indeed, local authorities, after all, have but a limited discretion in such matters.

The Prevalence of Zymotic Disease in Birmingham.

A LARGE amount of zymotic disease is at present prevalent in Birmingham. While typhoid fever and influenza are claiming their victims among the adult population, measles and whooping-cough are largely attacking the children of the town. According to the returns furnished to the medical officer of health by the chief school attendance officer during last week 70 fresh cases of whooping-cough and 187 of measles occurred among the children attending the board schools in the city. The effect so far of the prevalence of these diseases has been to reduce the attendances of the children to the extent of 2,000, thus causing a very serious interruption to the work of the schools. In this connection some discussion has arisen as to whether pertussis is or is not contagious. But there can be no question that it is a disease which is propagated by contagion. Infectious particles, no doubt, are thrown off by the cough and are conveyed to the air passages of other children, where they remain and multiply, thus causing the disease to spread together with the abundant reproduction of infectious material. Under all circumstances, therefore, wherever possible, isolation should be resorted to in order to prevent the dissemination of the disease. Although the board schools in Birmingham have not been closed, the health authorities have issued broadcast circulars giving directions to the parents and townspeople generally as to the best methods of preventing the spread of the diseases. This measure has, no doubt, proved useful, nevertheless it is evident that if the epidemics increase, a wiser plan would be to close the schools entirely.

The West London Post-Graduate College.

THE success of the West London Post-Graduate College is proved by the fact that although post-graduate teaching has only been carried on during the past three years no fewer than one hundred and sixty members of the profession, hailing from all parts of the world, have taken part in the courses. Moreover, we gather from a summary of the work of the college contributed to the current number of the *West London Medical Journal* by the Dean that there are now forty-two practitioners attending the present course of lectures and demonstrations. All this undeniably goes to show that the organisation of this undertaking has fulfilled the requirements of those in search of post-graduate tuition. It must be apparent to every one, that in this connection, access to a hospital, with the facilities for seeing the practice thereof, is an absolute *sine qua non* for the members of a post-graduate course. The complaint is often made by such that their requirements are not met by

a series of so-called set lectures. Lectures, as such, are reminiscent of early student days, and are not helpful where practical experience is needed. Hence there is little reason for doubting in part at least the success of post-graduate teaching is due in this instance to the advantages arising from the West London Hospital being included in the scheme, by which abundant opportunities are afforded for seeing hospital practice, and of making use of the clinical material provided by a large general hospital. We gather, also, that only qualified men are admitted to the post-graduate college, an arrangement which also has its advantages from a post-graduate standpoint.

A Libellous Certificate.

THE risks attending the certification of lunatics are serious enough under any circumstances to render the prudent practitioner circumspect in dealing with them. When a medical man goes out of his way to court disaster he is entitled to no sympathy, especially when the circumstances are such as tend to bring the exercise of this very important function into contempt. Mr. T. Anderson, who practises in the north of London, appears to have had differences of opinion with his milkman, and the latter, it is alleged, cherished hostile sentiments in regard to him. In what we may describe—mildly—as an unguarded moment, Mr. Anderson, availing himself of the facilities for literary composition afforded by a friendly public house, wrote a certificate to the effect that the milkman in question was a dangerous lunatic. He was so pleased with his production that he showed it to the barmaid, possibly to see if there were any mistakes in spelling. He ultimately left the document with the relieving officer, coupled with a hint that it would be well to secure the alleged dangerous lunatic. The medical officer of the union and the assistant divisional surgeon, having examined the subject of the certificate, both declared him free from any suspicion of mental aberration, and an action was tried last week in which the defamed milkman claimed damages for libel, with the result that Mr. Anderson was mulcted in £10 damages, a very moderate sum taking all the circumstances into consideration. A medical man who writes such a certificate in a public house in order to retaliate on a milkman whom he dislikes and then hands it round for inspection, cannot complain if the sequel is somewhat unpalatable. On the whole he has escaped pretty lightly, for some juries would doubtless have taken a much more serious view of the act of which he stands condemned.

The Need for Further Medical Assistance in South Africa.

ONE of the consulting surgeons at the front in South Africa has sent home word that even now the medical department is short-handed and that more surgeons are needed. The battle of Colenso is an instance in point. The great proportion of wounded which resulted from this engagement was more than the medical staff could effectually deal with, and many hours of continuous operating seems to have

been the lot of those who were present to attend to the wounded. Despite, however, the inexpedient strain to which, from lack of help they were subjected, the officers of the medical department are reported to have done their work excellently. But in view of the demand for further help the Government should lose no time in sending out more surgeons.

The Metropolitan Hospital Saturday Fund.

THE Board of Delegates of this Fund met on Saturday last to decide on the distribution of the awards for 1899, when it was reported that the gross receipts for the financial year ending the 8th inst. amounted to £20,023 5s. 3d. This income, mainly derived from the systematic workshop collection, was fully equal to the average, the cessation of the street collection and the various funds in relief of the sufferers by the war having had no adverse influence upon the contributions. It was decided to award, in respect of 1899, £17,013 13s. 8d., as against £17,029 17s. 5d. distributed for 1898. The latest awards made numbered 175, thus made up:—28 general hospitals, £6,367; eight cottage hospitals, £180; 60 special hospitals, £4,989 1s.; 31 dispensaries, £851 4s.; 20 convalescent homes, £1,688; 27 miscellaneous organisations (including ambulance, distribution, and surgical appliance committees, also institutions for gratuitous nursing of the sick poor in their own homes), £2,938 8s. 8d.; total, £17,013 13s. 8d. The principal awards were as under:—General hospitals: London, £883 8s.; St. Mary's, Paddington, £427; Middlesex, £404 12s.; Guy's, £401 16s.; St. George's, £338 16s.; King's College, £329; Seamen's (Greenwich), £295 8s.; Westminster, £294; North London or University College, £291 4s.; Royal Free, £285 12s.; Charing Cross, £264 12s.; West London, £204 8s.; Great Northern Central, £196; London Temperance, £183 8s.; German, £175; Metropolitan, £152 12s.; and Homœopathic, £144 4s.; Special hospitals: Brompton (chest), £427; Great Ormond Street Hospital for Sick Children, £305 4s.; National Hospital for Epilepsy, &c., £256 4s.; City of London Chest Hospital, Victoria Pk., £208 12s.; East London Hospital for Children, £203; Royal London Ophthalmic, £187 12s. The largest award given to a dispensary was that to the Western General, £58 16s. Convalescent Homes: Morley House, near Dover, £279 4s.; Metropolitan (Bexhill-on-Sea), £275; Metropolitan (Walton-on-Thames and Broadstairs), £275; St. Andrews (Folkestone), £162 8s. To the Hospital Saturday Fund Distribution Committee £1,360 was granted, and to the Fund's Surgical Appliance Committee £1,000, while £100 was awarded to the Metropolitan Provident Medical Association.

An Improved Medical Curriculum for the U.S.A.

WE are glad to chronicle the fact that our confrères in the United States are making a laudable effort to improve the curriculum of the different medical schools; and they are urging on the State authorities the desirability of a State Examination

Board where such a body does not exist. An attempt is being made to introduce a uniform standard of general education for admission to study in the various medical schools. From the *Occidental Medical Times* we learn that the John Hopkins school has set an ideal example. Harvard now follows in announcing that after June 1st, 1901, only persons having obtained degrees from recognised colleges will be admitted to study in the Harvard Medical School. Many require the equivalent of a High School education and insist upon obtaining it; others announce this requirement, but have no system of examining applicants. All the leading medical schools recognise the necessity of requiring four years for the study of medicine. Such colleges should be protected in the advance they are making by the State refusing the right to practise medicine to graduate from colleges not requiring so long a course.

St. Thomas's Hospital Surgical Home.

WE understand that some changes have been decided upon, and will shortly be carried out, in connection with the management of the Surgical Home at St. Thomas's Hospital. The present resident Medical Officer, Dr. Walter Edmunds, who has discharged the duties of the post since the Institution was started some fourteen or more years ago, will retire at the end of next month, and in his place there will be appointed a junior officer, holding the position of a house surgeon. The next change is that the "Home" will be thrown open for the reception of patients to be attended by their own medical men. From all this it would seem that the authorities have decided to work the institution upon a new policy, and to make the Home less of an appanage to the hospital. In other words, the adoption of these new arrangements will simply convert it into an ordinary nursing Home, with the advantage of having a house surgeon to look after the patients, under the direction of the attending practitioners, consultants, who may happen to be called in. It is proposed to give the junior officer a salary of £200 per annum, while Dr. Edmunds was receiving £500, thus a saving of £300 a year will be gained by the new policy about to be introduced.

The Decline of the Death-Rate.

A FALL in the weekly death-rate from 33.3 to 26.9 is welcome, and it may, perhaps, be taken as an indication that the epidemic of influenza is declining. Another explanation, however, would be that the proportion of old, weak, and ailing persons, of these who fall ready victims to the disease, is getting low. The experience of the last few years has shown that the weekly mortality follows a curiously smooth curve, rising steadily from week to week for a time and then as steadily declining. We are, therefore justified in hoping the acme is past. It is a noteworthy fact that influenza seems to flourish best during the mild winters, but the rule is not without exceptions, and it would not be safe to base any deductions as to its nature on this observation.

The Inquiry into Dublin Insanitation.

THE departmental committee which is to undertake this investigation is nearly complete. We reported last week that Dr. J. W. Moore, President of the College of Physicians, and Dr. R. L. Swan, President of the College of Surgeons, had been nominated by their respective colleges. The Irish Local Government Board will be represented by Mr. C. P. Cotton, late chief engineer to the board, but the delegate from the English board has not yet been named. The Corporation has nominated the Right Hon. Alderman Meade and Alderman Dowd but, as it was asked to nominate only one representative, and as compliance with its demand would give the Corporation a voting predominance over all other participants in the inquiry, it is not likely that more than one representative will be appointed. The Corporation, also, has urged that the evidence given before the Commission should be on oath, in which view we concur. Although we do not see that there is much to investigate save ways and means, all parties being already agreed as to the causes of Dublin insanitation, we consider that it is of the greatest importance that the verdict of the Commission shall receive the confidence of the citizens which it will probably not do if the testimony submitted to it is only verbal gossip.

The County Boroughs as Contributors to County Funds.

AN important test case was decided at Manchester last week in which the principle of the proportional liability of county boroughs to the general fund for the maintenance of lunatics was defined. Hitherto the county boroughs have paid on the rateable value of their respective areas, but under the Agricultural Act of 1896 the rates applicable to agricultural land were reduced by one-half, and it was contended that their respective contributions to the general fund should be reduced *pari passu*. This view, however, has not been endorsed by the Court of Appeal. It is now laid down that the gross rateable value is the proper basis for calculating the amount of the contribution and the reduction of the rates as applied to agricultural land does not interfere with the rateable basis. The point is obviously one of far-reaching importance, for a contrary decision would have thrown a heavy additional burden on the urban boroughs.

Mercer's Hospital, Dublin.

THE election of a surgeon to this hospital in place of Dr. Henry Moore, who has just been appointed to the City of Dublin Hospital in room of Mr. Wheeler, will not take place until the end of February. The names of candidates were to have been sent in yesterday, of whom there have been, probably, at least six. We have official knowledge, however, of only three. Mr. Harry Croly and Mr. G. B. White, already mentioned, and Mr. Burgess, formerly assistant surgeon to the Richmond Hospital, and an examiner in the Royal College of Surgeons.

Representation of Corporation on Hospital Boards.

AT the meeting of the Dublin Corporation last week it was intimated that the grant to Jervis Street Hospital would be opposed on the ground that the Governors had declined or omitted to elect any representative of the Corporation on the board. This was stated as a general principle applicable to all hospitals in future.

PERSONAL.

THE late Sir Richard Thorne-Thorne left an estate valued at £8,371 6s. 3d. including personality of the net value of £4,621 15s. 2d. —

DR. R. M. WILSON, of Duffield Road, Derby, has volunteered to accompany the local company of Imperial Yeomanry to the front. Mr. T. Aulton, veterinary surgeon, Derwent Street, will also proceed to South Africa with the detachment.

DR. JULIUS ALTHAUS has been elected an honorary member of the International Congress of Medical Electrology and Radiology, which will be held as part of the International Medical Congress, in Paris, in July next, and will deliver an address on the general indications of galvanisation and faradisation.

SIR WM. THOMSON leaves this country on Saturday to take charge of Lord Iveagh's Irish Hospital for South Africa. Dr. George Stokes, of London, second surgeon; Dr. Alfred Fivel, of Waterford, assistant surgeon; and Dr. James Coleman, physician to the Richmond Hospital, will follow in a few days with the full hospital equipment.

IN addition to the foregoing members of the Surgical and Medical staff, Mr. Francis Counihan, M.B., T.C.D., will take charge of the staff of dressers, having as his assistants Mr. John Pounden, M.B., T.C.D.; Mr. Percy Stewart, Mr. John McIlwaine, Mr. Douglas Thomson, and Mr. J. Edwards. The entire cost of the Hospital will be borne by Lord Iveagh.

WE understand that Dr. George Burbidge White, of Dublin, has presented to the Irish Field Hospital the complete apparatus of his double-chamber steam steriliser. He claims for it the advantages over every other such apparatus of portability and readiness for use at any moment, attributes of obviously great value in military service.

THE candidates for the seat vacant by the elevation of Sir John Lubbock as Parliamentary representative of the University of London, are Sir Michael Foster, Dr. Collins and Mr. Busk, the two first-named are members of our profession; all are well-known public men, and as a correspondent puts it, "distinguished in learning, science or literature." The choice is thereby rendered all the more difficult.

Scotland.

[FROM OUR OWN CORRESPONDENT.]

EDINBURGH ROYAL INFIRMARY.

THE Memorial Pavilion of the Queen's Diamond Jubilee is nearing completion, the builder's part of it being finished; and the managers of the Infirmary are commencing proceedings towards the erection of the two other blocks included in the original extension plan.

Warrants have just been granted giving them leave to build a new ear and throat position, and one for eye diseases on the ground to the north of the Jubilee gynaecological block, where the old disused laundry buildings stand.

The ear and throat pavilion consists of an administrative portion in the centre, three storeys high, with wings two storeys in height. The ground floor provides accommodation for the out-patients, with separate entrance, and consists of large waiting-room, examination-room, operating room, and large operating theatre. The upper floor consists of two wards for eight patients each and two small wards for two patients each; ward kitchen, doctor's and nurses' room, and the usual lavatory accommodation, with passenger and food lifts from top to bottom. The second or attic floor, over the administrative portion, consists of nurses' and servants' bed-rooms, bath-rooms, &c. The ophthalmological pavilion also consists of a central administrative portion, which is four storeys high, the wings at either side three storeys in height. The ground floor provides for the out-patients, with a separate entrance, and consists of large entrance hall and waiting-rooms for male and female patients, two large rooms for out-patients (clinic), dark-room, retiring-room, laboratory and surgeons' room. The two upper floors consist of two wards of ten beds each, dining-rooms for male and female patients, ward kitchens, nurses' rooms, operating-room, and the necessary lavatory accommodation, with passenger and food lifts. The attic floor of the central administrative portion contains bed-rooms and bath-rooms for nurses and servants. All the floors are fireproof, and the sanitary arrangements are of the latest and best description. The warming of the whole buildings will be done by steam pipes and radiators, and the exhaust ventilation by means of electric fans. Electric light is to be installed throughout. The new pavilions are connected with each other and also with the main medical and surgical hospitals by a light corridor of glass and wood, and the food for the patients will be conveyed to the new wards along this corridor from the main kitchen, which is at present being largely extended to meet the prospective increase of patients. The total cost will reach to about £45,000.

As a set-off against this expenditure the managers were the lucky recipients last week of the magnificent sum of £40,000, a donation given by Mr. Aitken, of Edinburgh, in memory of his wife. When the three new blocks are occupied, the number of beds available for patients in the Royal Infirmary and the affiliated convalescent house will, we believe, exceed those in every other hospital in the kingdom.

THE SURGEONCY TO THE QUEEN'S COUNTY INFIRMARY.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Your article on the above subject in last week's MEDICAL PRESS AND CIRCULAR is so inaccurate and misleading in many particulars that I venture to ask you in the interests of truth to place a more correct statement of the facts of the case before your readers. In the first place the name of the gentleman elected to the office on the 10th inst. is Niel Blaney and not Arthur Joseph McCauley Blaney, and he qualified in 1898 as M.B. of the Royal University, and not in 1893 as M.D. as you imagined. You further state that the surgeoncy was "occupied up to the spring of 1898 by Dr. William Jacob." Whereas the date of his election to the position was May 20th, 1898, whilst the Local Government Bill was passing through Parliament, and he remained in occupation until September 17th, 1899, when he was dismissed by the newly-constituted joint committee of management after his refusal to accept the option of resigning the dispensary appointment which he also

held. The "dominant party in the council" were not guided by any such motives as you attribute to them in the matter, and not a single one of the members of the committee appointed was ever asked to support my candidature for the position until after the vacancy was declared and advertised. As to my qualifications for it, even those who voted against me were obliged to admit that the Fellowship diploma of the Royal College of Surgeons obtained by me in 1887, after an honourable examination in the full curriculum and eighteen years' experience in the practice of my profession in this county, afforded more considerable guarantees for the efficient discharge of the duties of the surgeoncy than either the Licentiate certificate of Dr. William Jacob or its equivalent in professional status, viz., the M.B. degree of Dr. Blaney. The fact that I am Coroner for the county was the one sole objection raised against me. My tenure of the Stradbally Dispensary would necessarily be determined immediately in case of my election to the County Infirmary as I would be bound to reside within one mile of that institution. Only four of the members appointed by the council voted against me and three of the "original governors who supported Dr. Jacob" also joined them in electing Dr. Blaney by a majority of one. These are the facts, and your information to the contrary is entirely erroneous. If Dr. Jacob succeeds in establishing his claim to the office well and good. I did not oppose or challenge his occupancy at any time on personal grounds, and I am therefore neither "hoist" nor perturbed in any way as you pleasantly fancy by what has taken place. But should he fail in the proverbial uncertainty of the law it is just possible that another issue will then be raised before the case of the surgeoncy is finally disposed of, as some of the "original governors" who voted against me are liable to disqualification and other penalties for various reasons unnecessary to mention at present.

I am, Sir, yours truly,

THOMAS HIGGINS, F.R.C.S.I.

Stradbally, Queen's County,
January 22nd, 1900.

[The only error in our previous report was in the Christian name of the new surgeon to the Infirmary and we apologise for it. The fact is that the local newspapers gave different initials, and, on referring to the *Medical Register* and the medical directories, we could find but one Dr. Blaney, to whom, therefore, we credited the appointment. It appears now that the young gentleman selected possessed the same surname and exactly the same qualifications and had occupied the same positions in the same hospital as the gentleman named by us, but he is some years younger and had not been entered on the *Medical Register* until January, 1900, too late for the most recent issue of that book. For the rest, we have only to say that Mr. Higgins and the "dominant party in the County Council" must be judged by the pronouncement of their newspaper organs, and the editorials of those organs are extant to prove that, as we have said, the dismissal of the surgeon, the canvass for Mr. Higgins, and the ultimate election of Dr. Blaney, junr., were at no time anything more or less than a politico-religious job.—Ed.]

Obituary.

DR. GRIMSHAW, C.B., REGISTRAR-GENERAL FOR IRELAND.

ALIKE unexpected and unwelcome was the death of this valuable public officer and estimable gentleman, which was announced last week as the result of influenza and pneumonia. Dr. Grimshaw was born in 1839, and was the son of a well-known dental surgeon, Dr. Wrig-

ley Grimshaw. He married in 1865, in his twenty-sixth year, Miss Thomas, daughter of the Rev. Thomas. He finished his education in Trinity College, in which he was Moderator in Experimental and Natural Science, and Briggs Exhibitioner, and carried off several honours in Medical and Natural Science. He was a Fellow and Past President of the College of Physicians, and had filled the posts of lecturer in the School of Medicine at Steeven's Hospital, of physician to that institution, and to the Cork Street Hospital, and Dublin Orthopædic Hospital, and at the time of his death he was consulting physician to these institutions. Attention was called to his aptitude in statistics while he filled the post of President of the Statistical Society of Ireland. He served on several Commissions. He published various papers and articles on statistical subjects, and as Registrar-General had charge of the Government reports and statistics of births, deaths, and marriages, agriculture, emigration, railways, crime, and banking.

It is gratifying for us to look back upon the fact that the MEDICAL PRESS was the most earnest advocate of Dr. Grimshaw's claim to the high office which he filled when many other excellent competitors were seeking the position, and to feel that, in the long series of years during which he has occupied it, his administration of his department has more than justified the confidence which the public and the Government reposed in him. During his tenure of office more than one decennial census laid heavy burthens upon his responsibility and fully tested his capacity, while his reports on agricultural statistics were of great public service, outside the medical registration which was his daily work. He was a good-natured man, but also a determined Chief of department and, we are certain that, now that he has gone, there are very few who, could, with justice complain of his official actions.

Literature.

MACPHERSON'S MENTAL AFFECTIONS. (a)

THIS book is fittingly spoken of by the author as an introduction to the study of insanity. It is so from a high standard, and consists essentially of lectures delivered during several sessions to the students attending the class of mental diseases in the Royal Colleges' School of Medicine, Edinburgh. A glance at the outlines shows at once that the author takes a broad and at the same time a deep grasp of the subject, and that, while the scheme and detail of the book may be too much for the average student and practitioner, they will appeal to those who work in the same field and be helpful in advancing a more philosophic knowledge of the subject. The classification is a departure from what we are accustomed to in English text-books, but it is on right lines, though as in the case of general paralysis, the author taking perhaps too much for granted, we are not yet prepared to subscribe to the doctrine that it is a toxic insanity due to syphilis any more than we are prepared to dispute the counter statement that in either predisposing or exciting causation we find always a toxic influence. Dr. Macpherson has evidently been inspired by foreign writers, especially of the French school. His chapters on confusional insanity are very good. Here, however, we are much struck by the elaborate differentiation rather than by the clinical fulness of some of the descriptions. The term moral insanity is still retained, and we question if this is wise, for it is a most unfortunate term from a medico-legal point of view. On the subject of impaired or arrested development the author's writings are meagre, and the study of physical stigmata is not sufficiently differentiated. The study of the feeble-minded has become a very important one. The weakest part of the book is that on treatment, and though it must be admitted that we are far from advanced in this respect, many practical hints are still possible. The book is devoid of illustrations, but the author is probably wise in not repeating what

is already stereotyped. We commend this volume to those in the higher walks of psychological study, for it contains some excellent essays.

CHARTERIS'S PRACTICE OF MEDICINE. (a)

THERE must always be a large demand for a good epitome of medicine and therapeutics, the subjects, in their full extent, being so voluminous and incapable of being dealt with in a limited space. For this reason all judicious abridgments of the subjects have been well received by the profession, and this book, among them, has sold out seven editions and is now offered in its eighth. It has been brought up to-date by its present editor, who has received the assistance of Professor Stockman and Dr. Walter Colquhoun, of Glasgow University, and we consider that their task has been completed with as much accuracy as the necessary brevity of such an epitome will allow. Appendices are attached containing suitable prescriptions, formulæ and an abundant glossary of medical terms. On the whole, we can recommend the work to the busy practitioner or student.

EDINGER'S ANATOMY OF THE CENTRAL NERVOUS SYSTEM IN MAN AND VERTEBRATES IN GENERAL. (b)

THIS translation by Dr. Winfield S. Hall and others, is from the fifth German edition. The most striking merit of the work is that it presents the comparative morphology of the central nervous system. Part I. is introductory, and, according to the author, gives the fundamental ideas accepted at the present time. This is scarcely correct, for there are still difficulties in the way of accepting the conception of the structure relations, and associate function of neuron and neurona advanced by some able observers at the present time, indeed, to use the author's own words, "we stand still in the current of changing opinions." The first chapter is a review of the history and the methods of investigation of the central nervous system from which one gathers the impression that very little has been contributed by this country—scarcely a fair impression. The second and third chapters deal with the minute structure and relations of the neuron and with physiological processes, chapters of great interest, and very instructive. The physiological part scarcely rises above the simplest physiological processes, and while having established an anatomical idea of nervous structures, we should be interested in having the author's theory as to how the activities of mentalisation are produced, we must admit that he has stopped short on the threshold with discretion. The review of the embryology and comparative anatomy of the vertebrate brain is well done. Here, as elsewhere throughout the work, the illustrations are numerous and excellent. Beginning with the amphioxus, which practically possesses only a spinal cord, he illustrates by stages upwards the brain development of vertebrates. In some of the figures here the designations have not been rendered from German to English, which is rather unfortunate. The great bulk of the work is devoted to the third part dealing with the special anatomy of the mammalian brain with especial consideration of the human brain. While much of it has been gone over by writers and students again and again, there is much of fresh interest in view of the comparative anatomy studies here introduced, and this section is correspondingly valuable. The translators have done their work satisfactorily. They have found it necessary to interfere with the text, condensing, or omitting as the case may be. In some cases the rendering has been too literal, so that clearness of meaning is lost. These, however, are rare faults; and the work as an English addition to the literature of neurology is most acceptable.

(a) "The Practice of Medicine." By the late M. Charteris, M.D., Professor of Materia Medica and Therapeutics, Glasgow University. Eighth edition. Edited by his son, F. J. Charteris, M.B., B.Ch. Crown 8vo. Pp. 655. London: A. and J. Churchill.
(b) "Anatomy of the Central Nervous System of Man and Vertebrates in General." By Ludwig Edinger, M.D. American translation. H. K. Lewis and F. A. Davis and Co. 1899.

(a) "Mental Affections." By John Macpherson, M.D., F.R.C.P.E. London: Macmillan and Co., Ltd. 1899.

NEW BOOKS AND NEW EDITIONS.

The following have been received for Review since the publication of our last monthly list:—

BAILLIÈRE, TINDALL AND COX (London).

Experiments on Animals. By Stephen Paget, F.R.C.S. With an introduction by Lord Lister. Pp. 374, price 6s.

Aids to Materia Medica. Part III. (Concluding volume). *Synthetic Products, Glandular and Serum Therapeutics.* By W. Murrell, M.D., F.R.C.P.Lond. Pp. 84, price 2s. 6d.

The Pathological Statistics of Insanity. By Francis O. Simpson, L.R.C.P., M.B.C.S. Pp. 132, price 10s. 6d.

CASSELL AND CO. (London).

A Manual of Chemistry. By Arthur P. Luff, M.D., F.R.C.P., and F. J. Page, B.Sc., F.I.C. Pp. 541, price 7s. 6d.

J. AND A. CHURCHILL (London).

The Practice of Medicine. By the late M. Charteris, M.D. Eighth Edition. Edited by F. J. Charteris, M.B., Ch.B. Pp. 655, price 10s.

H. J. GLAISHER (London).

On Granular Kidney and Physiological Albuminuria. By Samuel West, M.D.Oxon., F.R.C.P.Lond. Pp. 198.

JAMES MACLEHOSE AND SONS (Glasgow).

Glasgow Hospital Reports. Edited for the Committee by G. S. Middleton, M.A., M.D., Henry Rutherford, M.A., M.B., and W. K. Hunter, M.D., B.Sc. Vol. II., pp. 402.

MACMILLAN AND CO. LIMITED (London).

Lessons on Prescriptions and the Art of Prescribing. By the late W. H. Griffiths, Ph.D., L.R.C.P. Revised, pp. 148.

KEGAN PAUL, TRENCH, TRUBNER AND CO. (London).

A First Book in Organic Evolution. By D. Kerfoot Shute, A.B., M.D. Pp. 285, price 7s. 6d.

YOUNG J. PENTLAND (Edinburgh).

The Edinburgh Medical Journal for 1899.

THE SCIENTIFIC PRESS, LIMITED (London).

Nursing in Diseases of the Throat, Nose, and Ear. By Macleod Yearley, F.R.C.S. Pp. 113, price 2s. 6d.

SIMPKIN, MARSHALL, HAMILTON, KENT AND CO. (London).

The Retrospect of Medicine. Vol. 120. July to December, 1899. Pp. 442, price 6s. 6d.

G. STEINHEIL (2, Rue Casimir, Delavigne Paris).

La Pratique des Accouchements, Obstétrique Journalière. Par le Professeur Henri Varnier, M.D., Paris. Pp. 440, avec 387 figures. Prix 26 francs.

JOHN WRIGHT AND CO. (Bristol).

Surgical Handicraft by the late W. Pye, F.R.C.S. Revised and Edited by Bertram Roberts, M.D., B.Ch.Oxon. Fourth edition, price 10s. 6d.

Medical News.

The Corporate and Medical Reform Association, Limited.

THE annual meeting of the Association, adjourned from December 30th, 1899, was held at the Holborn Restaurant on the 17th inst., Mr. George Jackson, F.R.C.S. Eng. (Plymouth), retiring President, being in the chair. The annual report was unanimously adopted. Since the last report the membership of the Association had increased from 40 members to 316, including ten affiliated societies, in the following order of joining: New Cross, Beckenham and Penge, Gateshead, Ilford, Mid-Tyne, Hartlepool, Wool Green and District, Hull, Bradford and West Riding Medical Union, Newcastle Medical Ethical Society. The arrangements for affiliation had been found to work harmoniously; and the finances were in a position of satisfactory and increasing stability. Officers and Council were unanimously re-elected. Dr. Jas. A. Myrtle, J.P., Mayor of Harrogate, president-elect 1898-99, then took the chair as President, and delivered a brief address, graphically mentioning the rapid increase of the Association, not only in numbers, but in its influence for good in the field of medical politics; and predicting still more rapid increase in both respects in the future. Mr. George Jackson, F.R.C.S. Eng., Plymouth, was chosen president-elect, and Dr. J. Higham Hill, F.R.C.S., Bedford Square, President of Council. The annual dinner took place after the business meeting had concluded.

A Compositor's Death from Lead Poisoning.

THE adjourned inquest on the body of a lad who had died of lead poisoning was resumed at Derby last week

It transpired that the deceased worked as a compositor, but took only tea in the office. It was stated that the lead dust adhering to the type would be capable of causing toxic symptoms, and a verdict to that effect was returned. The case is interesting in that type setting is not generally credited with being a dangerous trade, nor, with ordinary precautions, do we believe it can be so described.

Death of a Veteran Practitioner.

THE death is announced of Mr. Thomas Jones Dyke, of Merthyr, at the ripe age of 94. The deceased gentleman, who was known as the "grand old man" of the district, took his L.S.A. in 1837, and was elected a Fellow of the Royal College of Surgeons of England in 1866. He retired from practice in 1894. During a long and active career, Mr. Dyke took an active part in the sanitary administration of the town, he was made a justice of the peace, and for several years held the post of high constable.

PASS LISTS.

Conjoint Examinations in Ireland by the Royal College of Physicians and Royal College of Surgeons.

Final examination.—Passes:—

- A. Passed in All Subjects: F. G. FitzGerald, H. W. Spaight.
- B. Completed the Examination: E. J. Cane, R. J. Franklin, R. H. Moffit, T. D. Sullivan.
- C. Passed in Medicine: W. J. Anglim, C. C. Meeke, P. J. McGinn.
- D. Passed in Surgery: L. A. Hare, C. C. Meeke, J. H. O'Connell.
- E. Passed in Mental Disease.—W. J. Anglim, W. S. D. Bird, C. C. Meeke, P. J. McGinn, J. H. O'Connell.
- F. Passed in Midwifery: W. J. Anglim, W. S. D. Bird, M. M. Goldfoot, N. P. Kirby, C. C. Meeke, P. J. McGinn, J. H. O'Connell, D. Power.
- G. Passed in Ophthalmology: W. J. Anglim, N. P. Kirby, J. H. O'Connell, D. Power.
- H. Passed in Forensic Medicine, &c.: C. J. D. Odeiraine, D. Power.

Royal College of Physicians of London.

At a meeting held on Friday last, January 26th, the following candidates having passed the required examinations, were admitted members of the college:—

Edwin Bramwell, M.B., M.C.Ed., Walter L. Brown, M.A., M.B., Andrew Duncan, M.B., B.S.Lond., F.R.C.S., Charles O. Hawthorne, M.D., C.M., Robert Jones, M.D., B.S.Lond., F.R.C.S. and L.R.C.P., John M. H. MacLeod, M.A.St.And., M.D., M.S. Aberd., Clive Riviere, M.B.Lond., L.R.C.P., Alfred E. Russell, M.D., B.S.Lond., L.R.C.P., Alfred W. Sikes, M.D., B.S., B.Sc.Lond., L.R.C.P., Lewis A. Smith, M.B.Lond., L.R.C.P., Ralph H. Vincent, M.B., B.S.Durh., L.R.C.P.

The following candidates having passed the required examinations, received the diploma of L.R.C.P.Lond. at this meeting:—

A. P. Ambrose, M. Arango, F. Atthill, W. E. Bamber, B. S. Bartlett, L. J. Bartlett, F. E. Barwell, W. Bastian, H. W. Bayly, F. M. Bingham, A. F. Blake, F. D. Rindly, H. P. Bradley, W. P. S. Branson, E. W. Browne, C. A. D. Bryan, E. P. Burns, J. Cameron, T. Chetwood, H. N. B. Child, J. A. Churchill, H. N. Clarke, J. M. Collins, C. M. Cooper, W. E. Cooper, G. E. Cope, C. V. Cornish, J. F. Cunningham, A. H. Davies, P. C. Douglass, H. Durrbridge, G. M. Eastment, F. G. H. Edwards, T. C. English, R. Fell, H. W. Fisher, H. B. Foster, J. E. Francis, W. C. Francis, T. Gillespie, G. Gomez, A. S. Good, N. Grace, W. St. G. Grantham-Hill, W. H. Harland, F. R. M. Heggs, E. F. Hill, E. W. Holyoak, S. P. Hopewell, R. B. Horley, E. Hudson, J. W. Hunt, J. W. Illius, O. Inchley, A. W. Izard, F. B. Jeffries, B. G. Johnson, J. E. Judson, S. J. Kerfoot, R. B. Kinloch, C. Lees, H. S. Libby, L. Lindor, P. A. Loughurst, C. T. McClure, W. A. McEry, O. Marriott, H. A. Mason, R. W. H. Meredith, L. J. P. Mordaunt, B. W. Moss, P. T. Nicholls, C. North, J. W. Nunn, H. B. Nutt, H. J. Orford, V. B. Orr, A. J. Owen, T. D. Paddock, W. H. Park, J. F. Paul, A. C. Pearson, W. E. Peck, C. M. Pennefather, S. Pern, C. A. Peters, H. G. Pinker, R. N. Salaman, J. H. Sanders, E. M. Saunders, M. Sheehan, A. E. Softly, A. B. Spencer, G. H. Spencer, E. H. B. Stanley, H. Z. Stephens, P. G. Stock, W. Sutherland, W. B. B. Taylor, C. Thackray, H. Thwaites, B. B. B. Truman, W. E. Turner, J. Valerie, D. B. Von Rosen, B. A. Walker, E. Warren, R. N. Watson, C. H. Welch, W. B. E. Williams, R. Le G. Worsley, T. P. Yates.

Diplomas in public health were granted (jointly with the Royal College of Surgeons) to the following:—

John Allison, M.D., M.S. Edin., F.R.C.S. Edin. Univ., Arthur D. Cowburn, L.R.C.P. and M.B.C.S., M.D., Hugh E. Finch, M.B., B.C.L. Oxf., Harry P. Foulerton, L.R.C.P. and M.B.C.S., Shridhar Bheekjee Gadgil, L.M. and S. Bombay, Harry W. Henshaw, L.R.C.P. and M.B.C.S., John N. Martin, L.P.C.P., M.R.C.S., William D. Murray, M.B., M.S. Glas., Ernest J. Smyth, L.R.C.P., M.R.C.S., M.D., B.S. Lond., Alfred Spitteler, M.B., C. M. Madras, David J. Thom, L.R.C.P., M.R.C.S., Robert E. G. Tilleke, L.R.C.P. Ed., L.F.P. and S. Glas., M.D. Brussels, Frank H. White, L.R.C.P., M.R.C.S., L.S.A.

Notices to Correspondents, Short Letters, &c.

✉ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

ORIGINAL PAPERS.

The receipt of the following accepted papers is hereby acknowledged with thanks; their insertion will be proceeded with at once:—"The Operative Treatment of Uterine Fibroids," By W. J. Gow, M.D., Physician Accoucheur to St. Mary's Hospital; "The Risks of Unoperated Uterine Fibromyomata," By E. Stanmore Bishop, F.R.C.S., Surgeon to Ancoats Hospital, Manchester; "On Posterior (Congenital) Luxation of the Shoulder Joint," By G. Burbridge White, M.D., F.R.C.S.; "Therapeutic Notes on the Delirium of Coffee Drinking and Antipyrine," By George Foy, M.D., F.R.C.S.I.

UNPROFESSIONAL ADVERTISING.—We referred last week to an advertisement (which appeared in a Clonmel paper) signed with the name of Mr. Redington, of the Richmond Asylum, Dublin, in which his claim to be appointed Resident Medical Superintendent to the Clonmel Asylum was put forward. We felt ourselves compelled to rebuke emphatically the publication of any such advertisement by any member of the profession, especially by a Fellow of the Irish College of Surgeons; but we are now glad to be able to withdraw that censure, so far as publication of an advertisement is concerned, inasmuch as the Mr. Redington has repudiated the transaction in the columns of the paper in which it appeared, and the editor has admitted that Mr. Redington never ordered its publication, but that it was simply a copy of a semi-private circular issued by that gentleman to the Asylum Governors which had been shown to the editor by one of them and converted into an advertisement without any authority whatever, which, we take leave to say, seems to us to be a very strange way of editing a newspaper. We are not however prepared to withdraw our judgment that the manifesto would (even if limited in circulation to the Asylum Governors) be much more suitable "for a village stump politician than to a professional gentleman seeking a public medical office, as it places Mr. Redington's claims almost wholly on the ground of politics and religion, and lays little stress on his competency for the performance of the required duties."

THE COST OF A SMALL-POX EPIDEMIC.

The small-pox outbreak at Hull has been very costly to the people of that town. The Health Committee's expenditure up to the end of December was £28,000, and a further estimate shows that by the end of the financial year £41,000 will have been spent. This takes no account of £12,000 spent by the public in vaccination and revaccination whilst the scare was at its height.

Meetings of the Societies and Lectures.

WEDNESDAY, JANUARY 31ST.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN (Leicester Square, W.C.)—4.30 p.m. Dr. M. Dockrell: Erythema. (Post-graduate Course).

THURSDAY, FEBRUARY 1ST.

HARVEIAN SOCIETY OF LONDON (Staford Rooms, Tichborne Street, Edgware Road).—8.30 p.m. Clinical evening.

FRIDAY, FEBRUARY 2ND.

WEST KENT MEDICO-CHIRURGICAL SOCIETY (Royal Kent Dispensary, Greenwich Road, S.E.).—8.45 p.m. Paper:—Dr. S. Sunderland: Some Forms of Pelvic Pain in Women in which the Diagnosis was difficult. Dr. Herschell will demonstrate an Apparatus for Intra-gastric Shampoo, and the Three-way Tap for Lavage of the Stomach.

SOCIETY OF ANAESTHETISTS (20, Hanover Square, W.).—8.30 p.m. Discussion on the After-effects of the Inhalation of Ether on the Respiratory System, opened by Mr. S. Rombold (Leeds).

LARYNGOLOGICAL SOCIETY OF LONDON (20, Hanover Square, W.).—4.30 p.m. Discussion and Vote upon the Desirability of there being separate Sections for Laryngology and Otology at Congresses and Association Meetings. 5 p.m. Cases shown by Dr. L. Lack, Dr. J. Horne, Dr. Cathcart, Mr. Wyatt Wingrave, and Mr. Waggett.

ROYAL ACADEMY OF MEDICINE OF IRELAND.—Section of Anatomy and Physiology Communications.—1. The President: Protamines and their Cleavage Products—their Physiological Effects; 2. Professor Cunningham: Another Model of the Thoracic and Abdominal Viscera from behind; 3. Professor Coffey: Esophageal Glands of a Primitive type; 4. Professor Birmingham: The Form, Position, and Relations of the Stomach in Man; 5. Dr. C. J. Fatten: The Abdominal and Thoracic Viscera of the Gibbon; 6. Professor Birmingham: The Factors which Determine the Form of the Human Caecum.

Appointments.

BLAIR, A. B., M.B., C.M. Edin., Medical Officer for the Banwell (first) Sanitary District of the Axbridge Union.
DECK, E. J., L.R.C.P. Lond., M.R.C.S., Medical Officer for the No. 2 Sanitary District of the Borough of Hastings.
FORREST, J. S., L.R.C.P. Edin., L.F.P.S. Glasg., Medical Officer and Public Vaccinator by the Alnwick Rural District Council.
FRASER, S., M.B., C.M. Edin., Medical Officer for the Edmonton Sanitary District of the Edmonton Union.
HEDLEY, W. F., M.B. Edin., L.R.C.P., L.F.P.S. Glasg., Medical Officer for the Hullaton Sanitary District of the Uppingham Union.

HIGGINS, ALEXANDER G., M.R.C.S., L.R.C.P. Lond., House Surgeon to the West Kent General Hospital, Maidstone.
HOPE, A. A., M.B., B.S. Durh., Medical Officer for the Fifth Sanitary District of the Daventry Union.
LAMONT, J., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., Medical Officer to the Poplar Workhouse, London.
MCALL, ANTHONY, M.D. Glasg., Surgeon to the Throat and Ear Department, Roscombe Hospital, Bournemouth.
MACKIE, G., M.B., C.M. Aberd., Assistant Medical Officer for the Infirmary and Workhouse of St. George-in-the-East, London.
MANBY, E. P., M.D. Camb., M.R.C.S., D.P.H., an Officer on the staff of Medical Inspectors by the Local Government Board.
NEVINS, J. E., M.B. Lond., M.R.C.S., Medical Officer for the Workhouse, Liverpool.
PARSONS, H. F., M.D. Lond., M.R.C.S., D.P.H. Camb., Assistant Medical Officer and Medical Inspector for General Sanitary Purposes to the Local Government Board.
PERCIVAL, A. S., M.B. Camb., Honorary Surgeon to the Newcastle Eye Infirmary.
RHYS, WATKIN LLEWELLYN, L.R.C.P. Lond., M.R.C.S., Medical Officer for the Alderley District of the Merthyr Tydfil Union.
RIDLEY, WALTER, M.B., M.S. Dunelm, F.R.C.S. Eng., Surgeon to the Royal Infirmary, Newcastle-on-Tyne.
SMALLWOOD, SAVAGE, M.A., M.B. Oxon., F.R.C.S., Surgeon to the Wolverhampton Hospital for Women.

Vacancies.

Bath General or Royal Mineral Water Hospital, Bath.—Resident Medical Officer, unmarried. Salary £100 per annum, with board and apartments.
Bootle Borough Hospital, Liverpool.—First and Second House Surgeons. Salaries, senior £80, senior £50 per annum, with board, lodging, and washing. Apply to the Chairman, Bootle.
Borough of Southport.—Medical Officer of Health for the Borough. Salary £500 per annum. Apply to the Town Clerk, Town Hall, Southport.
Castletar Union.—Trained Night Nurse. Salary £60 per annum, with rations, and an apartment, fuel and light. Applications to Thomas M. Quinn, Clerk of Union. (See advt.)
City of Liverpool.—Assistant to the Medical Officer of Health. Salary £350 per annum, subject to certain conditions. Applications to the Town Clerk, Town Clerk's Office, Liverpool.
Gorey Union.—Camolin Dispensary. Medical Officer. Salary £120 per annum, with £15 a year as Medical Officer of Health and registration and vaccination fees, &c. Applications to R. Creighton, Clerk of Union. (See Advt.)
Grove Hall Asylum, Bow, London.—Junior Assistant Medical Officer. Salary at the rate of £120 per annum, with board, apartments, washing and attendance.
Hulme Dispensary, Dale Street, Stretford Road, Manchester.—House Surgeon. Salary £130 per annum, with apartments, attendance, coal, and gas.
Killadysert Union.—Trained Nurse. Salary £45 a year, with rations and apartments. Applications to Patrick Macmahon, Clerk of Union. (See advt.)
Loughborough and District General Hospital and Dispensary, Loughborough.—Resident House Surgeon. Salary £100 per annum, with furnished rooms, attendance, and board.
Nottingham City Asylum.—Second Assistant Medical Officer, unmarried. Salary £125, with board, apartments, and washing.
Nottingham General Dispensary.—Assistant Resident Surgeon unmarried. Salary £140 per annum, all found except board.
Royal Infirmary, Sheffield.—House Surgeon for three years. Salary £120 per annum, with board, lodging, and washing.
Ventnor Royal Hospital for Consumption and Diseases of the Chest.—Assistant Resident Medical Officer. Salary £100, with board and residence. Apply immediately to Dr. Parry. (See advt.)

Births.

MACLEOD.—On January 24th, at Harley Street, London, W., the wife of J. M. H. MacLeod, M.D., of a son.

Deaths.

ALEXANDER.—On January 26th, at Loup, near Ardrrossan, N.B., Surgeon-Major Alex. C. A. Alexander, of boydstone Army Medical Service, aged 45 years.
BOND.—On January 13th, at Greenwich Infirmary, Harry Bond, M.R.C.S., L.R.C.P. (St. Bartholomew's Hospital), of pneumonia after a short illness, aged 26 years.
BURGER.—On January 21st, at Finbury Square, London, Alexander Burger, M.D., suddenly aged 61 years.
CRISP.—On December 11th, 1899, at Newcastle, New South Wales, Thos Crisp, M.B., M.R.C.S., late of Chelsea.
DUNBAR.—On January 19th, Robert Pearson Dunbar, M.D., Park House, Blackburn.
EASBY.—On January 23rd, William Easby, M.D., L.R.C.P., L.M., L.R.C.S., of 6, Chatsworth Road, Brondesbury, N.W., late of Peterborough, aged 55 years.
HUGHES.—On January 22nd, at 40, Langham Street, Portland Place, London, Professor David Edward Hughes, F.R.S., aged 69 years.
HULME.—On January 25th, at 18, Philbeach Gardens, South Kensington, Edward Charles Hulme, F.R.C.S., aged 78 years.
POPHAM.—On January 24th, at his residence, 67, Bartholomew Road, London, N.W., after a short illness, Robert Honner Popham, M.D. St. And.
VERNON.—On January 16th, at Shipbrook, Cambridge Road, Southport, Henry Hannonite Vernon, M.D., F.R.S.E., aged 68 years. For 27 years Medical Officer of Health for Southport.

SOME REMARKS ON THE OPERATIVE TREATMENT OF UTERINE FIBROIDS. (a)

By W. J. GOW, M.D.,

Physician-Accoucheur to Out-patients, St. Mary's Hospital; Obstetric Physician to the Royal Hospital for Children and Women, and to the Metropolitan Hospital.

FIBROID tumours of the uterus are, unfortunately, of very frequent occurrence, and whilst on the one hand they may sometimes lead to but little trouble, they may on the other, seriously threaten life. Most often, however, they are a source of serious discomfort and ill health without actually endangering life, and though in a considerable number of cases the symptoms which they give rise to can be relieved to a very remarkable extent by medicinal treatment, yet it not infrequently happens that the relief is only partial, and sometimes no real improvement follows even the prolonged use of drugs. The question of operative treatment therefore becomes an important one, and there can be no doubt that of all the operations devised for dealing with this condition, hysterectomy is the one that is most certain to give complete and permanent relief. The chief factor which has kept this operation under has been the high mortality which has attended upon it, and even now by many it is regarded as one involving great risk. The sphere of usefulness of this operation would be greatly increased if it could be shown that the mortality from it need not necessarily any longer be a high one. The mortality of the operation for the removal of a uterus which is the seat of fibroid tumours is a matter, to my mind, of the utmost importance, because on the mortality of the operation turns the whole question of the indications for hysterectomy. So long as the mortality of the operation remained as high as 20 per cent. it is obvious that it was impossible to advocate removal unless as a last resort, and the patient was well-advised to put up with the troubles she had, rather than run the very considerable risk of losing her life which the operation exposed her to. It has often been insisted upon that fibroids seldom threaten life, but it is equally true that they often reduce the possessor of them to a condition of chronic invalidism, although after years of waiting the menopause may arrive and bring with it some measure of relief. If hysterectomy had no mortality, or if the mortality was very low, it is clear that the operation might be honestly recommended in cases where although the life of the patient was not threatened, the health was so seriously affected as to lead to inability to perform the ordinary duties of life with pleasure or efficiency. To a poor woman

who is in part or entirely dependent on her own exertions, long continued ill-health, resulting from excessive monthly losses of blood, is a serious matter, and the consequent inability to gain her livelihood renders waiting for the menopause an irksome or impossible task. Even among the well-to-do classes the loss of the best years of their life is hardly to be contemplated with equanimity, and if by a comparatively safe operation complete and permanent cure can be obtained, it is hardly fair to restrain them from seeking it. It is quite true that if the immediate risk to life from an operation is great it is better to wait rather than to run such a risk, so that the whole question of operative treatment turns on what that risk is.

The operation of abdominal hysterectomy will always be a formidable one, and often a difficult one, and one never to be undertaken lightly. A certain amount of shock is hardly to be avoided, and the opening up of connective tissue spaces will make blood poisoning easy unless sufficient precautions are taken. If, however, the seriousness of the operation is fully realised and every precaution which modern science has shown to be essential is taken, the risks of this operation may be reduced almost to a vanishing point. The operation is often not simple and not easy, and if performed by those inexperienced in abdominal surgery or in unsuitable surroundings or without every antiseptic precaution it will still undoubtedly be attended by a disastrously high death-rate. In such an operation as hysterectomy the penalty of inattention to detail is heavier than in the simpler one of ovariectomy. It is not uncommon for operators to still talk of a mortality of 10 per cent. as if it was a necessary evil which could not be avoided, but such a death-rate is a very terrible thing, and it is only when we realise the fact that there is no legitimate mortality in hysterectomy or any other operation that it will be reduced to within reasonable limits. An occasional accident will, I suppose, be always liable to occur, but apart from such a misfortune there should be, and I believe in time there will be, no mortality at all as the result of surgical operations.

If fatal cases are carefully studied, and they deserve study as much or more than those which are successful, the operator will generally be able to find out the reason in some fault of omission or commission, or if at a loss to do so he may with advantage seek the opinion of any experienced and candid friend who was present at the operation.

As to the relative advantages of the extra and sub-peritoneal treatment of the stump, the whole question again turns on the relative mortality of the two operations. Life is a more important consideration than any other, and if more patients live after the use of the serrenuud than after dropping back the stump into the abdomen no reasonable person would adopt any other method. It is for the advocates of the sub-peritoneal plan to show that their mortality is as low as that of the advocates

(a) Read before the Medical Society of London, January 8th, 1900.

of the older extra-peritoneal method, and it is on the question of mortality and on nothing else that either operation can claim to rise or fall. It is not necessary to show that the mortality of the sub-peritoneal method is lower than that obtained by the use of the serrenœud, because the former possesses certain intrinsic advantages of its own, such as a more comfortable convalescence and a firmer abdominal scar. Personally, I am a strong advocate of the sub-peritoneal plan, and in my own experience the mortality from this operation has been much less than that of the extra-peritoneal, and it has a further great advantage in that it is applicable to all cases. This is a very important point, because I do not think it can be said of any of the other radical operations for the removal of a fibroid uterus, such as pan-hysterectomy. Since September, 1895, I have employed this method in all cases of abdominal hysterectomy for fibroids, and during that time I have never had to fall back on oöphorectomy as a substitute. That is to say that in all cases where I set out with the object of performing an abdominal hysterectomy I have always been able to do it by this method. I cannot help thinking that those surgeons who habitually use the serrenœud meet from time to time with cases, where, owing to the absence of any kind of pedicle, they content themselves with removing the ovaries instead of removing the uterus. In my series of forty-seven cases, which form the basis of my remarks this evening, there has been no selection; they represent the entire number of patients (both hospital and private) on whom I have operated for uterine fibroids during the last four-and-a-half years with the exception of three or four cases, where vaginal enucleation was practised for the removal of purely submucous tumours. During that period I have never done an oöphorectomy in a case of fibroids. In all the cases the uterus with the tumour or tumours was removed at the level of the os internum, and the stump after being dealt with in the ordinary way, was dropped back into the abdomen. Drainage was only employed in one occasion (Case 40), the details of which I shall narrate shortly.

Among those forty-seven cases there has been one death (Case 8), and the table shows a series of thirty-nine consecutive cases of recovery, giving a total mortality of just over 2 per cent. My excuse for bringing forward this series of cases is that I hope to prove that abdominal hysterectomy properly performed is not so dangerous an operation as it is generally thought to be, and further that the sub-peritoneal treatment of the stump gives as good, or I believe better, results than any other plan. At a meeting of the Obstetrical Society of London held in November, 1897, Mr. Bland Sutton read a paper entitled, "On Abdominal Hysterectomy for Myoma of the Uterus; with brief notes of twenty-eight cases." In all these cases the sub-peritoneal plan of treating the stump was adopted. Two of the cases died, but he was able to show a series of twenty consecutive recoveries. Mr. Meredith, in the discussion which followed, stated that the serrenœud had given him 83 recoveries out of a succession of 90 abdominal hysterectomies (a mortality of 7.7 per cent.) including a run of 30 cases without a fatality. He claimed at that time that these results had not as yet, as far as he knew, been equalled by the advocates of the sub-peritoneal method. As I have shown in my own series, these results, admirable as they are, cannot only be equalled, but can be surpassed by the sub-peritoneal method, and no doubt Mr. Sutton and others could now produce series of cases considerably longer than my own in support of the same view, though as far as I know, no such tables have been published in this country up to the present time. It is often said that

the lessened mortality of to-day in such operation is due to the fact that it is done early, when the tumour does not reach higher than the navel. Although I certainly advocate the removal of tumours of this size under certain circumstances, I am sure that the operation is no easier than when the tumour is large and fills the abdomen, and this factor cannot be called in to account for the small mortality. In fact, speaking broadly, the larger the tumour the easier it is to remove, and an easy operation means a shorter operation, and therefore a lessened amount of shock. The success of this operation depends on two things, and two things only, viz., strict cleanliness and complete control of bleeding vessels.

INDICATIONS FOR THE OPERATION.

Even though the mortality of abdominal hysterectomy is reduced to 2 per cent. or less, it is obvious that we cannot recommend such a form of treatment in all cases of uterine fibroids. At a rough estimate probably not more than 10 per cent. of all cases of fibroids call for an operation such as this. Presuming for a moment that the mortality could be kept as low as this, even then it is not easy to lay down very definite rules as to the indications for operation. Large size, rapid growth, free hæmorrhage, great pain, or serious pressure symptoms are obvious indications. Pain is not a very common symptom of fibroids, but if present is, in my experience, generally incapable of relief by drugs. In its most severe form it is generally due to one or other of the fibroids projecting into the uterine cavity, and exciting irregular and painful contractions of a labour-like character.

The condition of life and the character of the patient must be taken into consideration, as has already been mentioned, poor women cannot afford to be partial invalids, and to some of those in easy circumstances ill-health is very irksome. To these, operation may be recommended, though the symptoms are not severe enough to justify one in urging it as a necessity. To some women, on the other hand, an operation presents so many terrors, that they prefer to remain as they are so long as their life is not actually threatened. In many cases all one can do is to point out to the patient that her choice lies between putting up with the symptoms she has got, or submitting to an operation, which is obviously not devoid of risk, but which, if successful, will result in a complete cure.

Tumours that fill the pelvis generally require removal sooner or later, and if they are already causing discomfort there is no object in waiting.

A question that it is often useful to ask oneself is whether it is probable that the patient will be able to go through the rest of her menstrual life if nothing is done. If the answer is in the negative then there seems to me to be really no object in postponing what later will become an operation of necessity. For instance, a woman, æt. 35, has a fibroid which reaches to the umbilicus, and is already the cause of some pain and a free monthly hæmorrhage, and medicinal treatment gives but little relief. It is extremely improbable that she will be able to pass through the next fifteen years of her life with even a reasonable amount of comfort, although the urgent need for an operation may not arise until she is forty-two or forty-three. With great care she may be able to hold out till then, but during that time she will have to live the life of an invalid. As the mortality now stands, I think it is better to advise an immediate operation and thus avoid the loss of many years of activity. It is true, as already pointed out that it is no safer, and no easier to remove a fibroid uterus at this stage than it will be when it is twice the size, and even the anaemia produced by the loss of blood does

not, unless very extreme, appreciably increase the risk of operation. But it puts the patient back into the world again at five-and-thirty instead of at five-and-forty, when invalid habits may very probably have become confirmed.

To sum up, the lessened mortality of abdominal hysterectomy enables one not merely to save patients from death but to save them from invalidism. Any patient who is seriously incommoded by a fibroid which does not yield to treatment and is not suitable for enucleation through the vagina, may fairly be advised to submit to an abdominal hysterectomy with sub-peritoneal treatment of the stump, provided the would-be operator has reduced his mortality to below 5 per cent. My own method of operating in these cases differs slightly from that employed by many others, and I therefore venture to describe the plan as now adopted by me, which I find applicable to all cases.

Various minor details have obtained a fictitious importance. Baer, for example, insisted that no ligature should be passed through uterine tissue, and attributes some of his success to this rule. Others have insisted on the importance of excising or sterilising the cervical mucous membrane. In the last 39 cases I have invariably ligatured uterine tissues, although the uterine arteries have been controlled by a separate ligature, and I have hardly ever excised or treated the cervical mucous membrane.

The plan of procedure has not been uniform because with increasing experience certain modifications have naturally crept in. In the last 30 or 40 cases the following plan has been adopted. After the peritoneal cavity is opened the tumour, when possible, is drawn out through the abdominal incision. If the broad ligaments are very short or the tumour is mainly intra-ligamentous and intra-pelvic, it sometimes happens that this cannot be done at this stage. Under any circumstances the first step in the operation is to ligature each round ligament about on a level with the os internum. The anterior flap of peritoneum is then marked out with a knife, and the round ligaments are divided on the uterine side of the ligature. This opens up the broad ligament, and with scissors the anterior layer may be divided, carrying the incision up towards the middle of the Fallopian tubes. The incision across the front of the tumour must be made sufficiently high to allow of the formation of a large anterior flap, and this flap is now stripped down with the fingers or the handle of a knife. The ovarian arteries and veins are next tied on each side by a ligature, which includes the Fallopian tube. This ligature, at any rate on one side should be tied so that at least one ovary is left, but if the fibroid occupies one broad ligament it is often more convenient to tie it on this side outside the corresponding ovary. Both ovaries should never be removed unless they are the seat of serious disease. Having tied the ovarian vessels on each side the broad ligament is divided on the uterine side of the ligature. Clamp forceps may be used to check the oozing which comes from the uterine end of the divided tissue. This is done on both sides, and then the posterior flap is marked out with a knife and dissected downwards for a short distance. The uterine arteries can now be generally felt without difficulty, and may be seized with a pair of pressure forceps at the level of the os internum. The tumour is now cut away with a knife, at the appropriate level, and the stump caught up and drawn to the surface with volsellum forceps. The uterine arteries are now carefully tied. This plan takes less time than if the arteries are tied before the tumour is cut away.

After this has been done I always introduce what I call a precautionary ligature, a curved needle on a

handle armed with silk is thrust through the stump from before backwards, avoiding the peritoneum so as to allow the ligature to include in its grasp the outer growth of the stump. This is tied on the outer side, and includes the uterine artery which, however, has already been tied separately. A similar ligature is now tied on the other side. The object of these ligatures is to control oozing from the cut surface. Vessels are given off obliquely, not horizontally from the uterine artery and, therefore, although this artery has been tied on the level of the cut surface of the stump there may be some bleeding point owing to a branch springing off from the main artery below the point where it is secured, and running upwards and inwards. Such vessels are often seen especially on the posterior half of the stump. By this means all oozing or spurting, as the case may be, is generally stopped at once, and even if there is no oozing it is a safe precaution as no harm results from thus enclosing uterine tissue in a ligature. Vessels in the substance of the cervix should never be tied on the face of the stump, as the ligatures will almost certainly come off. If oozing continues as it will sometimes in a very vascular stump a curved Hagedorn's needle may be used to encircle the bleeding area, and the tissue and vessels compressed with a ligature.

I think these additional precautionary ligatures are of value, because in the one fatal case which I have had (Case 8), death resulted from secondary hæmorrhage thirty-six hours after the operation as the result of the slipping of a ligature applied to a small vessel on the posterior part of the stump. In this case both uterine arteries had been tied in the ordinary way, but no precautionary ligatures had been used. At the post-mortem examination the uterine and ovarian arteries were securely tied, but about a pint of blood had escaped from a vessel on the posterior part of the stump which, at the time of the operation had been secured by a superficial ligature. Since then I have always employed these lateral ligatures and have never found that they have caused the least harm, and they afford a rapid and effectual means of checking oozing. In no case have I ever seen any ligatures discharged either through the abdomen or through the vagina.

In the fatal case above-mentioned the patient did very well for the first 36 hours, but in the middle of the second night she suddenly became faint and showed symptoms pointing to internal bleeding, and sank in a few hours before I had the chance of seeing her. I may add that probably the best way of dealing with secondary hæmorrhage from the stump if it does occur would be to excise the stump per vaginam, using clamps to control the uterine arteries. This would entail considerably less shock than reopening the abdomen and could be done rapidly.

After the oozing has been stopped I generally put in two fore and aft sutures through the muscular substance of the stump, again avoiding peritoneum, and in this way the raw surface is rolled together. They probably are of no great importance, but they serve to hold the stump up with, whilst the peritoneal flaps are united. After this has been done the peritoneum is cleansed, and the abdomen closed.

May I offer a plea in favour of the simplification of abdominal operations. Personally I seldom use more than six pairs of pressure forceps, and never more than six sponges. Further, I never have more than one assistant, and I never allow anyone but myself to touch my instruments and ligatures. I will not trouble you with other details as regards the management of sponges, but I hold that as few people should come within the circle of the operation as possible.

The desirability of leaving the ovaries seems still to be doubted by some, and we are told that after

the removal of the uterus they undergo slow atrophy, and thus a real menopause develops in spite of their presence. Even if this is the case it is still, in my opinion, highly desirable to leave one or both of them because by so doing the acute development of the climacteric is avoided. During the gradual atrophy the climacteric disturbances are in no way greater than when they supervene as the result of a gradual loss of physiological activity. Although I have not been able to follow all my cases since operation, yet I have seen many of them, and in no case have I met with any serious mental or bodily disturbance such as so often follows after oophorectomy.

The most serious complication at the time of operation is the presence of old adhesions between the enlarged uterus and the adjacent structures such as may result from a previous attack of perimetritis, secondary to trival disease.

In four of my patients (Cases 36, 39, 40, 42) a single or double pyosalpinx existed, and inasmuch as this condition is somewhat rare, I propose to narrate briefly the chief features of these cases.

Case 1.—This case was first seen by me on January 9th, 1899, in consultation with Dr. Sunderland. The patient was a widow and had never been pregnant. During the previous October and November she had suffered from abdominal pain accompanied by some pyrexia, and had been obliged to remain in bed for several weeks. On December 24th, she was suddenly taken ill with severe abdominal pain and vomiting, and the temperature rose to 104 degs. F. Since then the pain had become less severe, but the temperature still remained between 100 degs. and 101 degs. The patient was markedly anæmic and the monthly periods were profuse. On examination, a fibroid tumour was found reaching up to the umbilicus, but nothing further could be made out.

The operation was performed on January 12th, 1899, in a nursing home. Both tubes were found to be enlarged and adherent and contained pus. Both ovaries were enlarged to the size of hen's eggs and contained pus. The enlarged ovaries lay deep down by the sides of the supra-vaginal cervix. The uterus was first cut away to give more room, and then the appendages were dug out after much difficulty. Pus escaped from both tubes and ovaries during removal. No drainage was employed. Convalescence was normal.

Case 2.—This patient, æt. 50, was admitted to the Royal Hospital for Children and Women in June, 1899, complaining of profuse irregular hæmorrhage. A large tumour the size of a six months' pregnancy occupied the abdomen. On vaginal examination a tumour the size of an orange could be made out in Douglas's pouch, and another similar tumour lay in front of the cervix. At the time of the operation the abdominal tumour was found to be the enlarged uterus, and the other two tumours were the Fallopian tubes distended with pus. The uterus with both ovaries and tubes were removed. The convalescence was remarkably smooth.

Case 3.—This patient was æt. 35, and was seen by me with Dr. Squire at the Paddington Infirmary. She had been taken ill three weeks before admission with severe headache and abdominal pain, and a week later she became delirious and remained so till after the operation. When seen by me the abdomen was distended and tender, the temperature was raised, the tongue was dry and brown, and there was noisy delirium. A fibroid tumour reached as high as the navel. The cause of her illness was obscure, but as her condition was very grave an operation was decided on. I performed hysterectomy on July 3rd, and both appendages were then found to be enlarged and very adherent. They were removed with great difficulty, and found to contain offensive pus. There was free oozing from the pelvis and a drainage tube

was therefore inserted. The oozing continued for the first twenty-four hours after the operation. Two days later the discharge from the tube became offensive and remained so for several days, but ultimately the patient got quite well.

A TABLE OF FORTY-SEVEN CASES OF ABDOMINAL HYSTERECTOMY FOR FIBROIDS WITH SUB-PERITONEAL TREATMENT OF THE STUMP.

St. M H—St. Mary's Hospital. M H—Metropolitan Hospital.
R H C W—Royal Hospital for Children and Women.

Case 4.—The patient was 42 years of age, and was admitted into St. Mary's Hospital for severe menorrhagia and abdominal pain. There had been pyrexia for some weeks before admission and the patient was very ill. There was a fibroid tumour which reached up to the navel, and in the left posterior quarter of the pelvis a smooth elastic swelling could be felt, the size of a hen's egg. At the operation, September 14, 1899, the left tube was found converted into a pyosalpinx. It, together

with the uterus, was removed. Both ovaries were left. There was a good deal of oozing from torn adhesions, but no drainage was employed. The patient made a good recovery.

It has been impossible in the time at my disposal to do more than touch on some of the points of interest in connection with this subject, but my chief object has been to support the view that of all the radical operations for fibroids, abdominal hysterectomy with sub-peritoneal treatment of the stump is the best and the safest, and that this operation may confidently, in the future, be looked to to give a mortality of not more than 1 or 2 per cent.

THE DILATATIONS AND DIVERTICULA OF THE ŒSOPHAGUS.

By JOHN KNOTT, M.A., M.D., CH B., and Dip.
Stat. Med. (Univ. Dub.); M.R.C.P.I.; M.R.I.A.; &c.

IN the issue of THE MEDICAL PRESS AND CIRCULAR bearing date December 27th, 1899, there appeared a short article under the head of "Notes on Current Topics," under the title of "Sacculated Diverticula of the Gullet." The general tone of this article, and the well-known fact that all pathological conditions of the œsophagus are, comparatively speaking, of great rarity, have led me to think that the publication of my notes on the various forms of dilatation of the walls of this important tube might not prove unwelcome to the readers of the journal.

In one of the issues of the years of infancy of THE MEDICAL PRESS AND CIRCULAR (January 27th, 1841), a report will be found of a lecture delivered to his class by Dr. Charles Benson, then Professor of Medicine in the Schools of Surgery of the Royal College of Surgeons in Ireland, and Physician to the City of Dublin Hospital, where his reputation has been so well sustained in the present generation by his sons—Dr. Hawtrey Benson, who is now its consulting physician, and Mr. Arthur Benson, its distinguished oculist. At that date, the dawn of the golden era of Irish Medicine, it is interesting in the present connection to find the following remarks recorded in the language of one of its most brilliant representatives:—"An organ so well supplied with arteries and nerves may be conceived to be liable to inflammatory and nervous affections. Its muscular coating exposes it to spasmodic affections, its strong cellular or nervous coat to more permanent contractions, and the exposure of its mucous membrane to all the varieties in the temperature, and in the other qualities of bodies with which it is incessantly coming in contact, might be expected to render it very subject to disease, yet I cannot say that it is very subject to disease of any kind. Walk through the hospitals in Dublin for weeks together, and in the long catalogue of diseases you may not see one of the œsophagus."

Diseases of this portion of the body do, however, occasionally occur, and with, as might be anticipated, peculiarly fatal results. And the malformations and dilatations of which it is sometimes found to be the seat, are, perhaps, pathologically unique in this peculiarity of being more painful than, and almost as surely fatal as, the most malignant structural changes known to affect its walls.

Returning now to the section of œsophageal pathology with which the text of the present communication is more immediately concerned, I propose to divide these abnormal conditions of the gullet into *congenital* and *acquired*. The varieties of each of

these divisions may in turn be very conveniently and scientifically arranged, in accordance with the classification of Rokitansky, under three heads:—

1. The *cylindrical* or *fusiform*, in which a great part of the length of the tube is engaged; or, as sometimes happens, the whole length of the pharynx and œsophagus presents this modification.

2. The *sacciform*, in which pouches (one or more) are found, which involve all the coats of the œsophagus.

3. The *hernial*, in which the mucous membrane alone expands; and this coat, protruding through the muscular layers, forms *diverticula* or *herniæ*.

The first variety is rarely met with, whether the abnormality be congenital or acquired. In the recorded cases, the amount of dilatation has been, however, generally very great.

The accompanying illustration (Fig. 1) is copied from Virchow's Archiv (Bd. XLII., Taf. XI.), and pictures a case of enormous fusiform dilatation of the œsophagus, recorded by Luschka, which was not accompanied by any appreciable narrowing of the cardiac orifice, compression, or other obstruction in its vicinity.

Fig. 1.

The specimen had been removed from the body of a woman, æt. 50, who had had, from the age of 15, the power of vomiting at will. During the latter years of her life she had often vomited blood. The œsophagus was found to be 40 c.m. in length, and 30 c.m. in circumference at the widest part. The muscular coat was greatly hypertrophied. The mucous membrane seemed to have been the seat of acute catarrhal inflammation. There is no doubt in my mind that this case originated in congenital abnormality.

A case of simple dilatation of the œsophagus was met with by Zenker in a seven months' babe, which survived its birth only to the seventh day. Had it survived for some years I have little doubt that it would have grown into something like the original of the above figure.

The most instructive case of this kind which, so far as I can find, has hitherto seen the light, is one in which the patient had lived to old age, but had

suffered all through life from the symptoms of œsophageal obstruction. The abnormal œsophagus was brought under the notice of the Pathological Society of London (May 1, 1866) by Dr. (now Sir) Samuel Wilks, who was then rapidly growing in the fame, as pathologist and physician, which his subsequent career has so well sustained. The patient had been under the care of Dr. Rootes, of Ross, for whom the specimen was shown.

FIG. 2.—Dr. Wilks's case of dilatation of the œsophagus. At the upper end the thickness of the coats is intended to be shown in section. At the lower end is seen the narrowing of the tube just above its junction with the stomach.

"The specimen had been taken from the body of a man of seventy-four who had died of pneumonia. He had suffered all his life from dyspepsia. He had consulted Sir A. Cooper for this forty years before. He had always been obliged to eat slowly and carefully, and to wash down each bolus with a draught of fluid. He never partook of a meal of which he did not bring back some portion, so that he had been, in fact, a ruminating animal. The œsophagus was as large as an ordinary-sized colon, and its calibre was pretty uniform throughout. It was six-and-a-half inches in circumference in the undistended state. The cardiac orifice was narrower than usual, barely allowing a finger to be pressed through, but there was no trace of disease to account for this contraction. The walls of the tube were very much thickened by increased muscularity. The stomach was normal." The accompanying woodcut figure is that of the specimen. (From "Guy's Hospital Reports," Vol. XVII., 417.)

The patient himself used to account for the origin of his condition by his straining himself in the manipulation of heavy weights. Dr. Wilks had no doubt that the dilatation had been congenital. The existence of a congenital cardiac constriction, which seems highly probable, would, of course, have continuously aided in the gradual expansion of this enlargement, which was almost certainly only slight at the period of birth. This view appears to me to be very much strengthened by the fact of the co-existing hypertrophy of the muscular walls, which must have been produced by the ever-recurring abnormal effort required to overcome a fixed obstacle.

In such cases the muscular coats of the tube are found to be hypertrophied, whereas in those of acquired—secondary—dilatation, the opposite condition of atrophy—with attenuation—is very often met with.

Sacciform dilatation of the œsophagus, although an infrequent, is a well-known condition. In a large proportion of these cases, the abnormal form of the expanded portion of the tube has represented pretty accurately the auxiliary digestive pouch which is found in birds—the "crop" of the Hibernian poultry-yard, "crop" of the up-to-date cookery-book, and *ingluvies* of the ornithological anatomist.

Specimens of this congenital abnormality have been placed on record by Grashuys and by Vicq-d'Azyr. I am inclined to think, with Mondiere, that a large proportion of the cases of dilatation of the œsophagus which have been observed in later life, really originated in some such congenital disposition, which served as a starting point, and which afterwards became exaggerated by the detention of food.

An interesting case of dilatation was published by Dumas (*Recueil periodique*, XXIII., 59), in which the lower portion of the tube was engaged. He believed that the origin was a congenital malformation. The ultimate development was such, however, as to suggest to him a very strong resemblance to the first stomach of a ruminating animal.

A similar form of abnormality has been recorded by M. Della Chiaga, of Naples. An enormous dilatation of the lower part of the œsophagus was found, "forming a tumour, or rather a pouch analogous to the first stomach of ruminant animals, and in which the ingesta remained for some time, to be afterwards rejected by a kind of regurgitation. The muscular walls of the pouch were of extraordinary thickness." No definite diagnosis had been made during life: death had closed a period of dreadful suffering, which had lasted many years. M. Della Chiaga believed the origin of the condition to have been a congenital malformation—small at the time of birth, and gradually increasing by yielding to the pressure of retained ingesta.

Blasius (*Obs. Med. Rariores, Amstelodami, 1677*) describes as a specimen of *double stomach* one of which I entirely agree with the opinion expressed by the late Sir Morell Mackenzie, "from his own report, and the rough drawing which accompanies it, was undoubtedly an instance of dilatation of the lower part of the gullet." The original report is as follows:—

"*Ventriculus duplex*.—In dissecto cadavere 35 annorum creberrimis vomitibus diu vexato invenimus Ventriculum duplicem, ita ut *prior*, qui Oesophago continuus, ab *altero* qui intestinis, manifeste distingueretur. Ille minor altero, est crassioris substantiæ, infinitis plicis, iisque insignibus, interior exasperatus, hic verò iis omnino destituebatur, tenuis valde conditionis. In illo fibre carnosæ plurimæ occurrebant varii generis, in hoc vix ullæ, saltèm haud adèò observabiles. Locus ille, ubi duæ hæc cavitates à se invicem separabantur, interior valde angustus erat; sic ut vix digitum minimum reciperet; substantia ipsa hic crassa, duraque admodum, mollioris quasi car ilaginis speciem referens. Et hanc angustiam frequentioris vomitus in hoc agrotante causam fuisse conjicio."

The only confusing element in the above case would appear to be that the dilatation, so far as we can judge from the very sketchy description, seems to have been limited to the sub-diaphragmatic section of the œsophageal canal. The next "Observatio" recorded by the same author is one in which the section of the œsophagus situated between the heart and diaphragm presented a saccular expansion, "quasi Ventriculus."

"De duplicitate stomachi quæ propono, cum fre-

quantius occurrant admirationem haud adeò movent eo, quod non ita pridem videre contigit in dissecto corpore alio Viri toto ætatis tempore valde famelici, alias benè sani. Oesophagus hic, in Thorace, intra Cor and Diaphragma, insigniter dilatus, singulare quasi *Ventriculum* constituebat, utroque enim extremo angustia maxima notabatur, ubi nempe gula hæc dilatari incipiebat, & ubi iterum ad statum debitum accedere. *Kugosa* etiam hæc cavitas intus observabatur, materia ex albo flavescente eaque lentâ satis obducta. Ab hoc Ventriculo per orificium uti diximus summè angustum transitus erat, ad duorum transversorum digitorum distantiam, in Ventriculum verum, qui naturalis omninò constitutionis erat, sive substantiam species, sive locum, aliave."

The language used in the above "report" leads me to think that after all the writer may not have looked upon the sac in the first case as an additional "stomach" in the ordinary anatomical sense of the term. The remarkable feature in the latter case would appear to be the absence of any troublesome symptoms.

The existence of the *third form* of oesophageal dilatation of Rokitsky's classification—in which a sac is found by a *hernial protrusion of the mucous membrane* of the tube through an opening in its muscular coat—has given rise to a good deal of discussion among pathological anatomists. *Monro (Morbid Anatomy of the Gullet and Intestines)* long ago admitted it among the varieties of dilatation met with in this canal, but does not seem to have had any stronger reason for doing so than its analogy with what is sometimes seen in the intestines, and more particularly in the walls of the urinary bladder. He thought that in consequence of a strong spasmodic contraction of the muscular fibres of the oesophageal wall the mucous membrane might be so pressed as to form a hernial protrusion between their bundles, and that the pouch originally so formed went on increasing indefinitely from the pressure of the ingesta which lodged within it. *De Guise* also attributed their origin to a hernia of the mucous membrane which took place during the pressure called forth in the act of deglutition; and he thought that this explained the fact that they are most frequently seen at the junction of the upper end of the oesophagus with the pharynx. He believed that he had seen a case of this kind occurring in a horse, but his own account of his observations does not lead me to believe that he had made a careful dissection of the parts.

Mondiere, in the whole course of his elaborate researches on affections of the oesophagus, did not meet with a single well-authenticated case of the kind. On the other hand, *Crucillier*, as the result of his own observations, concludes, with *Monro*, that hernial pouches are sometimes formed in the oesophageal wall, similar to those found in the rectum and bladder.

A very striking example of this form of pouch-like dilatation was exhibited to the London Pathological Society by *Dr. Ogle*. The specimen was taken from the body of a man, æt. 63, who had died of pneumonia. He had suffered from difficulty in swallowing for many years before his death. When his meals were concluded, small portions of the food used to return into the fauces and buccal cavity, and this process of regurgitation used to continue with more or less activity for several hours. For two or three years before death he had been subject to attacks of laryngitis; from which, however, he had always appeared to recover completely. It had been suggested that a stricture of the oesophagus existed; but no special treatment was ever adopted. On post-mortem examination no stricture was found. The upper part of the pharynx was found to be enlarged, with its muscular fibres greatly hypertrophied, while from the posterior wall of the canal, at the level of the junction of the muscular fibres of the inferior constrictor of the

pharynx with the upper border of the circular muscular fibres of the oesophageal wall, sprang a pouch of about the size of a bantam's egg. This pouch involved only the posterior and lateral portions of the circumference of the tube. It projected downwards behind the oesophagus, and its wall was apparently formed by a portion of the mucous membrane and submucous tissue protruding between the bundle of muscular fibres. It did not appear to contain any muscular fibres in its wall, and this opinion was afterwards confirmed by microscopic examination.

The accompanying woodcut gives a view of the parts from behind. The oesophagus and pharynx have been laid open, and a piece of catheter introduced, to demonstrate the continuity of the tube.

Fig. 3.

The existence of a weak section in the wall of the tube at the junction of the upper end of the oesophagus with the adjacent lower border of the inferior pharyngeal constrictor is known to every anatomist who has made a careful dissection of this region. The unyielding surface of the cricoid cartilage in front must necessarily form an accessory factor in conveying the pressure of a large bolus with specially effective force on this part of the tube. So that the existence of even slight congenital atony in this region must almost certainly proceed to progressive dilatation. A case has been recorded by *Féré* in which one square millimetre of the anterior wall of the oesophagus, near the upper extremity of the tube, was absolutely deficient in muscular tissue. This, in the opinion of *Mackenzie*, "furnishes a possible explanation of the mode of formation of some oesophageal pouches."

Habershon, who adopted *Rokitansky's* classification of dilatations of the oesophagus, also gives an instance which he had met with in *Guy's Hospital*. The patient had died of peritonitis resulting from perforation of the ileum during typhoid fever:—

"At the commencement of the oesophagus was a pouch half an inch in length, consisting of the mucous membrane, and very slightly covered at the neck with a few muscular bands; it was full of mucus. (Prep. 1784.) This form is most frequently

seen near the bifurcation of the trachea: it is found of largest size at the lower end of the pharynx."

A description of a somewhat similar case has been placed on record by Bell. I cannot find in the literature of the subject any definite corroboration of Habershon's statement that such (small) pouches are "most frequently seen near the bifurcation of the trachea."

(To be continued).

CASE OF POSTERIOR (CONGENITAL) LUXATION OF THE SHOULDER JOINT.

By G. BURBIDGE WHITE, M.D., F.R.C.S.,
and Diplomate in State Medicine, Univ. Dublin.

CONGENITAL dislocation of the shoulder is a rare surgical affection, posterior luxation is the most unusual form which it assumes, the usual forms described are of the sub-acromial type. In early infant life it is difficult to recognise, as the superabundance of fat in which the shoulder is encased gives a roundness to the joint which disguises it, and also purposeful motion takes place to a limited extent, little information is obtained from this source.

I. B., *æt.* 11, was brought to me in September, 1898, to see if anything could be done to give him more use of his right arm, which he had not, up to this time; the mother of the boy said that some time after birth it was noticed he did not use his right arm as well as the left, and the opinion was that the nurse had let him fall. Nothing appears to have been done for him till he grew up to about seven years of age, when some doctors in the country were consulted, with the result that the parents were recommended to take the child to Dublin and consult a surgeon there, which was done.

A thorough examination of the joint was made by me on September 1st, with the result that I discovered the following conditions:—There was decided angularity of the right shoulder, with a prominence in front of the shoulder, the head of the bone was absent from the axilla, movement (passive) of the arm caused that of the scapula, total inability to move the arm or forearm, to pronate or supinate, or to flex or extend the hand. The forearm was turned in so that the dorsum of the hand rested on the loin. There it would hang except he moved it with the other hand, in fact, the boy had no idea how to move his upper extremity; if he had, the extreme atrophy of the muscles would have rendered it impossible for him to do so. Considerable atrophy of the head of the bone gave some mobility to the joint. The diagnosis made was: Posterior luxation (sub-spinous, probably congenital), of the acromial end of the clavicle, atrophy of the head of humerus and of the muscles of the extremity, the biceps was remarkable in appearance, being about the size of a walnut when contracted by passively flexing the forearm. The general appearance of the patient suggested a tuberculous diathesis; the right side of the chest was sunken, and a very stooped posture was present; poor appetite and general debility; treatment was undertaken guarded by a cautious prognosis. I have to acknowledge, with thanks, the great help given me in clearing up the origin of this lesion by Mr. Henry Gray Croly, F.R.C.S., Senior Surgeon City of Dublin Hospital, who on inspection pronounced it to be congenital; his ripe experience in surgery inclines me to coincide with this view of the case.

The line of surgery carried out in the case was, in addition to remedying the stoop by a suitable appliance

fitted to the back, holding the shoulders backward, and throwing out the chest, was, first, careful and prolonged massage of suitable kind, carried out by a skilled masseuse, while manipulation of the head into a more forward and better position effected a considerable change in the location of the head, bringing it into a better position so that it could be felt in the axilla, and in this improved position motion of the arm became more possible, independent of that of the scapula, which was fixed by a towel when carrying out passive exercise of the muscles of the upper arm, the muscles of the forearm were similarly treated, and after some months a slow improvement in the size of the muscles was visible, and also in their movements, and by degrees effort was made at voluntary movement of certain muscles by the boy himself. When this had improved considerably, the exercises were extended to the use of dumbbells, and an American elastic exerciser; improvement now became more rapid; when some ordinary movements such as putting on the hat, lifting small weights, &c. were performed. At the end of twelve months there was great progress both in the movements and their extent and power; the muscles had considerably developed, and some of the awkwardness of action had disappeared, the health had shown also marked improvement from the habitual exercises. At the present time, after about twenty months' treatment, it may be fairly stated that a great deal of the use of the arm has been acquired, and the absolute inability to move has given way to quick and well-executed movements, for example, he can dress, put on his collar and tie with both hands, use his knife and fork, put on and take off his hat, &c. and with a little guidance lift his teacup without spilling to his mouth. He is now beginning to learn what it is to have a right arm and hand, and it may be fairly assumed that, with practice, it will not be long before he is in possession of a thoroughly useful right extremity. Skiagraphs and photographs were taken at the different stages of progress, fully bearing out the diagnosis. These, with further notes, on the affection, I hope to bring forward at a future time.

SOME REMARKS ON THE OILS OF CAJEPUT AND CUBEBS AND THEIR USE FOR INHALATION.(a)

By ROBERT J. LEE, M.D. CANTAB., F.R.C.P. LOND.

THE question of how to use certain volatile oils in the form of vapour is one of great interest, and certainly of very great importance. It is a singular fact that when we mix some of these oils with water and then boil, we find that the steam will carry them with it, although the temperature at which the oils boil is very much higher than that of water.

In the case of cajeput oil the boiling point is between 482 degs and 509 degs.; and yet it will evaporate when boiled with water.

What we have to determine, however, is whether the quantity of the oil that evaporates in this way varies in this process; that is to say, whether the oil comes off rapidly like menthol or benzoic acid, and leaves the water soon free of it; or whether only a certain part of the oil escapes, leaving behind a residue. Phenol, some years ago, was shown to evaporate equally with the water, so that we could obtain steam carrying phenol in definite proportion. With cajeput oil I have recently found that we can secure a similar result; and that if we mix two drachms of the oil with half a pint of water, and then evaporate one half of this mixture at 212 de. s., the remaining half will contain one drachm of the oil,

and when the quantity is reduced by further boiling, the water and oil are found to remain in the same proportion.

The oil of cubebs boils between 480 degs. and 500 degs., and so does not differ much in that respect from the cajeput. There is also no very great difference in the specific gravity, that of the former being 0.929 and of the latter 0.885. They both evaporate equally with water.

It appeared to me at one time difficult to understand why we neglected the use of certain medicinal agents in the form of vapour, but the reason became apparent when our want of knowledge of how vapours can be obtained for such use was considered. The conversion of a fluid into a spray is not the same thing as its change into a vapour, and we are still in want of experiments accurately carried out on the best methods of changing certain solids and fluids into vapours, before we can use them in practice. The oils of cajeput and cubebs may be vaporised without difficulty, and as their properties are well understood it is unnecessary to make any remarks on the class of cases in which they may be inhaled with benefit.

Clinical Records.

WESTMINSTER HOSPITAL.

Case of Acute Chorea treated with large doses of Arsenic.

Under the care of Dr. MURRELL.

ADA W., æt. 6, was admitted on November 6th, 1899, with chorea of some weeks' duration. It was her second attack, the previous one, for which she had been in a hospital, having lasted four months. Her symptoms now were perfectly typical, and need no description. There was an mitral aystolic murmur. She was kept in bed and given plenty of good food. Visitors were not admitted. On November 12th she was started on 1 minim of liquor arsenicalis three times a day, and the doses were gradually increased as follows:—14th, 2 minims; 15th, 3 minims; 18th, 4 minims; 21st, 5 minims; 23rd, 6 minims; 27th, 7 minims; 30th, 8 minims; December 6th, 9 minims, all three times a day after meals. There was no improvement in the patient's condition until the 9 minims dose was reached, but a few days later the movement had practically ceased, and on the 15th Mr. H. T. Barron, M.B., who had been keeping careful watch over the patient, discontinued the treatment. On the following day she vomited eight times, there was a copious loose motion, and she complained of pains in the abdomen. On the 15th she vomited only once, but on the 16th she was sick nine times between seven and eight o'clock in the morning. She vomited twice after her dinner that day, and that was the last of the symptoms of arsenical poisoning. There was no dermatitis or pigmentation, there was nothing characteristic about the tongue, and the patellar reflexes, although slightly diminished whilst the patient was under treatment, were never lost.

REMARKS BY DR. MURRELL.

This is an attempt to treat a case of acute chorea according to Murray's method. It will be remembered that Dr. Wm. Murray, of Newcastle-on-Tyne, in his excellent and most suggestive "Rough Notes on Remedies" advocates the employment of fifteen drops of liquor arsenicalis three times a day in all cases of chorea in children. He insists that it should be taken with food, that is, in the middle of a meal. If it does not cure the patient in a week it must be dropped, as the toxic action of the drug would show itself. In this particular case we did not strictly follow Murray's directions. We gave too small doses, and kept up the treatment for too long a period. In other cases, where we have commenced with 15 minims doses, no inconvenience has been experienced, and there has been an almost immediate improvement. The old-fashioned idea that patients with chorea got well just as quickly on rest and feeding

and without the administration of drugs is now exploded. The duration of the attack is immensely shortened by giving arsenic.

France.

[FROM OUR OWN CORRESPONDENT.]

PARIS, February 3rd, 1900.

PRECÆCAL ADENITIS.

At the Société de Chirurgie, M. Gérard said that three times he observed precæcal adenitis, independently of appendicitis, and it appeared to him to be of a tuberculous nature. In one case he perceived in the right iliac fossa a tumour of the volume of a large walnut, in a young girl who had presented twice over signs of appendicitis. In operating, he found to his great surprise that the appendix was absolutely healthy, but there existed in front of the cæcum two large ganglions, one of which appeared to have suppurated. The histological examination confirmed the healthy condition of the appendix; as to the ganglions, they presented a caseous aspect, but the proof of their tuberculous nature was not made. Another patient, age 28, suffered for five or six years from repeated pain in the iliac fossa. The speaker operated thinking to find an appendicitis; in this case also the organ was in the normal condition, but, on the other hand, a ganglion of the size of a walnut was found adherent to the anterior face of the cæcum. He should add that the last patient, as well as the first, was of tuberculous stock.

M. Quénu said that he thought that under the name of para-appendicitis could be designed quite a group of inflammatory processes developed around the terminal portion of the ileum and the cæcum, and comprising the ganglions spoken of by his colleague; of this he had observed several examples. In a patient of seventeen, to whom he had been called a few weeks before a sudden pain in the right iliac fossa, and signs of grave peritonitis appeared following an attack of ordinary grippe. He pronounced the case to be one of appendicitis, and operated the same evening. The appendix was found to be only very slightly congested, but the surface of the cæcum was covered with pseudo-membranous exudations in which were found streptococci and colibacilli.

TREATMENT OF FURUNCULOSIS.

Dr. Gallois communicated the results, quite extraordinary, which he obtained in the treatment of boils and wounds in general by the application of salicylate of methyle. The liquid form of the drug has the advantage of being applicable in wet dressings. Employed in the pure state by rubbing, and on extensive wounds by linen steeped in it and covered by oil silk, salicylate of methyle provokes but the slightest pain. M. Gallois considered it as an excellent antiseptic, preventing the formation of pus and stimulating the granulation of the wound.

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, February 3rd, 1900.

At the Free Society of Surgeons last week, Hr. Hernes related a case of

SIMULTANEOUS EXTRA- AND INTRA-UTERINE GRAVIDITY, occurring in a woman of 30, who was admitted into the

Moabit Hospital in September, 1898. She stated that her menses had appeared two months before, and that the evening before admission she had been suddenly seized with spasmodic pains, with loss of breath, and that during the night she had suffered from vomiting and singultus. On admission she was extremely anæmic, very little blood issued from the vagina. There was meteorism and dulness over the dependant parts; the uterus was enlarged, and to the right of it some resistance was felt. The patient recovered from the collapse, and on the 13th, nine days after, laparotomy was performed. A large quantity of clotted blood was found in the abdomen; the right tube was ruptured, and removed along with the ovary. Chorionic villi could be seen on the wall of the tube.

Recovery took place, but some weeks afterwards when the patient was leaving the hospital, the uterus was found still further enlarged. Four weeks later she returned, and complained of vague pregnancy pains, and on examination the suspicion was aroused of a four months' pregnancy, and further examination showed the suspicion to have been well founded. At the end of the period the patient was naturally confined.

ANTIPERISTALSIS.

Hr. Mühsam followed on with a note on the above subject which he had endeavoured to solve experimentally, carrying out to a further extent the experiments of Kirstein. He had cut through the intestine at the border between the duodenum and jejunum, and also at the entrance of the latter into the cæcum, and had attached the cæcal end to the duodenum, and the duodenal end to the cæcal, in order to determine whether such a condition as antiperistalsis really existed. Most of the animals (dogs) died before anything could be ascertained. One dog took nourishment and had a stool before ileus set in, on the twentieth day. Laparotomy was performed, and the symptoms were found due to adhesions. When he separated them gas immediately passed from the upper to the lower part, but the animal soon died. The section showed that of 485 c.m. of intestine, 430 were reversed, so that only 55 retained their original direction. In the material vomited both digested and undigested food was present, showing that peristalsis had still continued in the normal direction. In another dog, operated on in the same way, intussusception had taken place. The remarkable part of this was that the neck of the invaginated part was found directed upwards towards the stomach, also showing that energetic peristalsis had taken place in the normal direction.

In the *Sammlung Klin. Vorträge*, m. 225, Dr. A. Martin discusses the subject of the

LATE CONDITION OF OVIOTOMISED WOMEN.

Ventral hernia is first discussed. Extra-peritoneal treatment of the pedicle, abscess formation in the wound, and drainage all favour the later development of hernia, through the wide and irregular cicatrix that forms. The most important essential for prevention of hernia is the careful adjustment of sutures in layers, instead of suturing in mass, and in support of this the writer adduces the statistics of Winter, Abel, and his own, all showing a distinct diminution in the number of herniæ since the introduction of suturing in layers. An equally valuable factor is union by first intention. But in a certain number of cases, in spite of asepsis and suturing

by layers, hernia will form. He always makes his patients wear a binder, but pads should not be worn. After a year or two the bandage can be replaced by a corset reaching to the pubes with an elastic inlet. Hernia can often be avoided by a carefully regulated diet. He remarks on the fattening treatment now too much in vogue, that often in later years leads to the stretching of cicatrices and the formation of herniæ. As regards the treatment of herniæ, as a rule they cause little disturbance, and as they show but little tendency to cause incarceration, the support of a belt or corset is generally all that is required. In extreme cases operation must be performed, including suturing in layers again. The hernial sac should be removed so thoroughly that the whole of the peritoneal covering is removed.

He then goes on to discuss the effects of removal of the ovaries. Besides the typical symptoms usually described, there are sometimes vicarious bleedings from the nose and rectum, and even from the stomach and lungs. (Your correspondent saw it in one case from the bladder), and in four cases a very troublesome eczema came on. Therapeutically, he recommends scarification of the portio, or leeches or cupping. Regarding the treatment by ovarian substance, he gives an English preparation and in rather small doses, but on the whole his opinion of the treatment is not particularly favourable. At the same time his statistics of the treatment in the natural menopause, or in cases in which the ovaries, whether along with the uterus or not have been removed, the effect was quite satisfactory, as there was a transient improvement in over 50 per cent. of the cases. He suspects there must be a suggestive action, but no control experiments were made with a view of testing the accuracy of the suspicion.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, February 3rd, 1900.

SENILE EPILEPSY.

At the "Medical Club" Redlich brought forward the subject of senile epilepsy, in which he endeavoured to prove that early attacks of epilepsy in life were the prodroma to the final "insult" which was commonly attributed to preceding hæmorrhage or general enfeeblement. To this form of epilepsy belongs cerebral tumours and the presence of cysticerci, of which he recorded two of the latter coming under his own immediate observation.

True senile epilepsy in its symptomatology differs little from that occurring in the young. Its ætiology is usually traced to heredity (which Redlich considers very doubtful), injury to the cranium, alcoholism, acute infectious disease which is rarely met with, and chronic cerebral disease. Redlich here related a case of the latter disease which recently came under his notice. The patient had suffered from psychosis for a long period, till one day, quite suddenly and unexpectedly, he took a fit, which persisted ever afterwards. One of the most important factors in the production of senile epilepsy is undoubtedly arterio-sclerosis which Naunyn has so emphatically asserted as the only cause. Compression of the carotid can hardly be denied as another very potent agent in its production as anæmia of the brain is produced analogous to experi-

ments carried out in animals. This leads us to consider another type of cardiac epilepsy arising from some imperfection of the heart. In contrast to the anæmic theory of epilepsy we often have described a congestive form. It has been asserted from this connection of heart disease and epilepsy, that the former is the cause of the latter which Redlich will not accept, but assumes that two diseases co-exist, and that the treatment of epilepsy should not be bromide of potassium for the fits, but rather some hæmætic or cardiac drug.

In the pathological anatomy of senile epilepsy there were often found a number of lesions, and he described some where he has met with "miliary sclerosis," but he would not speculate on the value of its presence.

To differentiate senile epilepsy, the history will often be found incomplete. In one case of his own there was present left-sided hemiparesis, where subsequently a morbid centre was found in the right hemisphere of the brain. In many other cases he has met with difficulty of speech, being followed by the epileptic fits which often closely resembled progressive paralysis.

In other cases of the same class, amnetic aphasia is often followed by similar attacks. It has been asserted that this epilepsy never proceeds to dementia, but Redlich is unwilling to discuss that hypothesis. Lauterbach thought that a causal connection existed between heart disease and epilepsy, and cited a case of congenital cardiac fitium with dextro-cardia in his 37th year, becoming affected with epileptic fits.

Schlesinger had for many years collected a record of cardiac affections in connection with epilepsy, but failed to find any direct cause and effect.

Redlich thought Lauterbach's case of epilepsy in connection with heart affection too remote for substantiating proof.

WOUNDING THE FACIAL NERVE.

At the Gesellschaft der Aerzte Biehl showed a young man, æt. 22, who in July, 1898, got a stab from a knife on the left ear, wounding the facial nerve and producing paralysis of motion in the movements of the face on the same side. In addition to this there was jerking of the left angle of the mouth with loss of sensibility and vasomotor disturbance, which confirms some of the experiments conducted in animals.

In chewing, the left side of the face became bathed in perspiration extending to the nose and lower jaw, while the right side was perfectly dry. In taking fluid food or when amyl nitrite and pilocarpin were injected this phenomenon was absent.

The Operating Theatres.

GUY'S HOSPITAL.

AMPUTATION THROUGH THE THIGH FOR PERIOSTEAL SARCOMA OF THE UPPER END OF THE TIBIA.—Mr. ARBUTHNOT LANE operated on a boy, æt. 17, who for some months had walked lamely, the knee being kept slightly bent. The patient paid no attention to this condition, but a month ago he struck his knee whilst getting into a cart, and on undressing the same evening he noticed a swelling where he imagined he had been struck. This was seen some time after by a medical man, who aspirated it, and only obtained blood. On admission to the hospital, the knee was slightly flexed owing to a mass in the popliteal space. This was continuous with

a thickening about the head of the tibia, which in front formed a round mass nearly as big as a tangerine orange. The patient having been anaesthetised, the growth was freely exposed, and found to be periosteal in character. The limb was amputated through the thigh just below its centre by circular incisions which divided the skin, muscles and periosteum in different planes. Mr. Lane said a section of the specimen showed that the swelling brought about by the injury was a hæmorrhage into the soft growth.

AMPUTATION THROUGH THE ARM FOR SARCOMA OF THE SKIN OF THE FOREARM.—The same surgeon operated on a man, æt. 48, who some weeks after the receipt of an injury to the forearm noticed a small lump as large as a Brazil nut beneath the skin of the part. He was seen by his medical attendant, who found a mass attached to the deep fascia, and involving the skin. In its immediate vicinity there was a small separate nodule in the skin. These were removed by the doctor who cut very free of the growths; the wound healed most satisfactorily. A short time, however, another nodule was observed in the vicinity of the scar, and later, on his admission to the hospital, several minute nodules could be felt, distributed over a considerable area. The question then arose as to whether, in the face of the very malignant character of the growths, it would be better to remove the skin, fascia, and subjacent muscles, or to afford the patient more security by amputating through the upper arm. The situation having been made perfectly clear to the patient he decided to have his arm amputated without delay. This was done by the circular method through the upper arm just below its centre. Mr. Lane strongly approved of the choice made by the patient, as he considered that the removal of soft parts necessary to effect a complete ablation of the growths would have left the arm almost useless, and might very likely not have obviated recurrence in the skin which would have been left. In both the above operations the principal vessels of the limb, he said, had been exposed and occluded before the muscles were divided transversely so that hardly any blood was lost at the time of the operation.

In both cases recovery was rapid and complete.

GREAT NORTHERN HOSPITAL.

GALL-STONES IMPACTED IN CYSTIC DUCT.—Mr. PETTON BEALE operated on a woman, æt. 40, who had been admitted complaining of intense paroxysmal pain in the right hypochondrium. There was a swelling to be seen, and on examination under an anæsthetic there was little doubt about its being a distended gall-bladder. The onset of the symptoms had been gradual, and there had never been any jaundice. An incision was made over the region of the gall-bladder and parallel to the costal margin about four inches long; in opening the peritoneal cavity the gall-bladder was at once seen very pyriform in shape, measuring about five by three and a half inches; on feeling it, it was found to be full of gall-stones, and two could be distinctly felt in the cystic duct. Cyanide gauze having been closely packed round the gall-bladder, the latter was then pulled out of the wound as far as possible, freely opened and its contents, consisting of inspissated and foul smelling bile, together with seven stones, the largest an inch in diameter, were removed; the organ was freely washed out with lotion. The removal of the stones impacted in the cystic duct was then undertaken; the first, a small one, came away with ease; the second, about $\frac{1}{2}$ ins. in diameter,

gave great trouble, as it appeared to have set up, ulceration of the cystic duct at some time previously, and this had resulted in cicatricial contraction above and below the stone, so that no manipulation by scraping, forceps, &c., could remove the calculus or break it *in situ*, nor could it be grasped by forceps. An incision was therefore made in the wall of the duct over the stone, and the latter removed. This incision was closed as securely as possible, and the wound in the gall-bladder sewn up. The greater part of the abdominal wound was then closed a gauze plug being left at one end. Mr. Beale said that under such circumstances some escape of bile into the general peritoneal cavity could not be avoided. He ventured to state that in nearly every case where the gall-bladder was incised some considerable local intra-peritoneal inflammatory disturbance was found to take place. It was, he thought, as common when the edges of the gall bladder were stitched to the wound as when they were united and the viscous dropped back, and as this was the case, he preferred generally to close the gall-bladder at once without waiting to suture it at a future operation, especially as in the latter procedure one could not be certain of preventing the entrance of bile into the peritoneal cavity.

“SALUS POPULI SUPREMA LEX.”

WEDNESDAY, FEBRUARY 7, 1900.

THE CHARITY ORGANISATION SOCIETY.

THE policy and methods pursued by the Charity Organisation Society have long since incurred the dislike and distrust of the poor, and have raised misgivings in the minds of not a few thinking philanthropists. Recent events appear to have filled the measure of popular discontent and to have deprived the C. O. S.—as it is familiarly termed—of the sympathies of many of its supporters. As everyone knows, in answer to the appeal for monetary aid for the widows and orphans of British soldiers killed in South Africa, and for the wives and families of

reservists called to the colours the purse strings of the people were freely opened and huge sums of money poured into the relief fund. It is much to be regretted that some wise plan for distribution in common was not determined upon by the various collecting agencies. One of the latter, the Soldiers' and Sailors' Families' Association, called in the aid of the C. O. S. in distributing their monetary help. The result might have been readily foreseen by anyone familiar with the tortuous and dilatory detective policy of the society in question. The pith of the whole movement lay in the speedy supply of enough ready cash to support the wives and families of those who had gone off to fight our battles in a distant country. Funds were ample, needy wives and families were a multitude; to bring the one to the other would seem a simple task to ordinary folk. The Charity Organisation, however, proceeded on their customary lines, their inquiries covering such ground as arrears of rent, moral character, the existence of pawn tickets, possible sources of income, and the circumstances of friends. Pending this inquisition families were left to starve, as attested by numerous letters sent by reservists' wives to the Guardians of Stepney, Greenwich, Poplar, Walworth, St. George's-in-the-East, Deptford, Marylebone, and other Metropolitan districts. Such a burst of indignation followed these disclosures that the services of the society were at once dispersed with, and henceforth it is to be hoped that the kindly generosity of the nation will reach its recipients untainted by the poison of suspicion and the unfor-iveness of past offences. Better a thousand times that a host of undeserving folk should be relieved than that one worthy applicant should be deserted in this time of need. Besides, what have past misdeeds to do with the matter at all—except in the unchristian creed of the C. O. S.? Surely if the husband and the father of the family has shouldered his rifle and gone to the front he has purged himself of a vast deal of offence by freely offering his life to the service of his country! Any man good enough to fight for us deserves our care for those he has left behind him, and no organisation is wanted to rake up reasons for withholding that relief. The underlying policy of the C. O. S. in regulating present relief by past peccadilloes seems to be on the face of it hopelessly and radically wrong. Disease and want are not less in need of assistance because the sufferer has pawned his boots, and not paid up his rent, or has been on some previous occasion convicted of drunkenness. At the same time it may be admitted that the work of the C. O. S. is legitimate so far as it prevents habitual rogues and imposters from preying on the charity of the community. It seems abundantly clear, however, that the inquisitorial methods of the Society have long since carried it outside any such reasonable limit. Here are some facts published by Mr. Thomas Farrow, who has paid a good deal of attention to the subject. In 1897, out of the total income of £19,462 15s. 5d., no less than £10,888 0s. 7d. was swallowed up in salaries, rent, office expenses, publications, district secretaries, agents in training

and money invested abroad. Last year the total income was £16,565 5s. 3d., of which £12,320 15s. 4d. was absorbed in the way mentioned. The balance, £4,245 9s. 11d., being presumably spent on grants and committees, but only the paltry sum of £138 1s. was definitely stated as having been spent in charitable relief. During 1897 applications for relief were made to the Society to the number of 17,814. Of these, 2,021 were withdrawn, presumably owing to the objectionable nature of the Society's investigations. Of the remaining 15,793 assistance was refused to 8,269 persons, who were thus virtually treated as impostors. Of the 7,524 who were assisted, 4,614 received help from "institutions or local agencies," 2,708 were helped by "individuals," and 193 were referred to Board of Guardians. Among other literature the Society issues an expensive journal, and a bulky "Annual Charities' Register and Digest," the production of which must cost a large sum of money. How far the condition of the suffering poor of the United Kingdom is bettered by such an outlay remains to be proved. Certainly at the time of its introduction there was no need for the annual register as the ground was already covered by an excellent publication of a similar kind. On the whole it seems that the C. O. S. itself is in need of a vigorous overhauling as regards both its money expenditure and its methods among the poor. An independent official inquiry would set the mind of the public at rest, and there is no obvious reason why a society professing so high a code of moral ethics should shrink from such a proceeding. Members of the medical profession would welcome any sound machinery for the exclusion of improper applicants for medical relief, but meanwhile they will be inclined to echo the ancient query, "*Quis custodiet ipsos custodes?*"

MEDICAL SOCIETIES AND MEDICAL JOURNALS.

MEDICAL societies and medical journals, viewed as means of generalising information bearing on the progress of medicine, cover very much the same ground and are consequently in the position of rivals. There was a time, before medical journalism had been evolved from chaos, when the medical society afforded practitioners virtually the only opportunity of comparing notes and inviting criticism, a time which, archæologically, occupied approximately the same place in history as the systematic lecture does, or did, in medical education. When books were rare and costly oral teaching enabled the diligent student to compile his own notes, but since teaching has been systematised in books these selfsame lectures have lost their *raison d'être*, though they still survive in virtue of that uncompromising conservatism which characterises pedagogues of every denomination. In the same way the necessity for medical societies has to some extent disappeared because the object for which they exist is better filled by publication in the medical journals. A lengthy contribution embodying the concrete results of much labour and research requires sustained attention and

concentrated thought before it can be assimilated, and these are only possible on condition that opportunities are afforded for its perusal. It follows that societies have been driven to take steps to enable intending speakers to obtain communication of the paper in advance, either by anticipating publication in their *Transactions* or by furnishing printed abstracts. Obviously a much simpler plan would be to publish the paper beforehand in the medical journals. This would economise time in that it would be unnecessary to devote half the evening to the reading of the paper, while, on the other hand, those who are interested in the particular subject would have ample opportunity of thinking the matter over, and of preparing their own observations. We should in this way avoid the *fiasco* which is so frequently the lot of the best description of papers; indeed, so far as discussion is concerned, the best papers offer the least scope therefor, simply because, if replete with facts and observations and closely thought out, no one is ready, on the spur of the moment, with remarks worthy of the occasion. Not very long since most medical societies were very jealous of their proprietary rights in the papers read at their meetings, and although this rule has of late years been somewhat relaxed, the majority still restrict the right of publication to their own "*Transactions*." This, from all points of view, is a foolish and selfish policy, for it virtually confines the writer of the paper to the limited publicity of his fellow-members. A fabulous amount of money is wasted year after year in the publication of expensively got-up volumes which are immediately relegated to the shelves of the library, so that the object aimed at, which we suppose is the diffusion of knowledge, is to a great extent frustrated. If this rule were abrogated a much larger publicity would be gained in the medical press without the expense entailed by these bulky "*Transactions*," and authors would cease to feel tempted to reserve their best work for the much larger public commanded by the medical journals in lieu of interring it in the quasi-obscure of the "*Proceedings*." Another not inconsiderable advantage would be that much more space could be devoted to the discussions, which are often more interesting and instructive than the paper on which they are based. After all, the reflections and conclusions of an author only constitute an *ex parte* statement, and their value is only established by discussion, in the course of which omissions are remedied, doubtful points elucidated or dismissed, and illogical conclusions dissected and adjusted. For some years past the societies have experienced steadily increasing difficulty in getting men to come forward with papers, in consequence of the temptation to seek publicity in the medical journals, and unless they modify their rules and adapt themselves to the new order of things this difficulty cannot fail to go on increasing. The multiplicity of medical societies is another source of trouble, yet we look in vain for any indication of a desire to join hands. The death of Sir Andrew Clark cut short a movement which

might conceivably have culminated in a federation of existing societies—a consummation devoutly to be wished in the interests of the societies themselves. As a means of disseminating technical knowledge, medical societies have to a great extent been superseded by the medical press, but they have a special rôle of usefulness which will ensure their survival in spite of adverse circumstances. They afford practically the only opportunity for kindred spirits to come into contact, and they tend to break down the isolation which is fostered by the ordinary routine work of practice. Since this, after all, is their special sphere, it is a matter for surprise that those who are responsible for their management do not do more to cultivate the social element, an idea which the genial Sir Edward Sieveking and Mr. Timothy Holmes, as past Presidents of the Royal Medical and Chirurgical Society, did their best to inculcate. Another department in which the societies may be expected to achieve popularity is the clinical evening. The Royal Medical and Chirurgical Society is almost alone in not having introduced this “great attraction.” All societies profess the desire to enlist the general practitioner; but he, busy man, has little taste for the more recondite subjects which constitute the *pieces de résistance* of the proceedings, while he displays a lively interest in the practical knowledge to be gained by the inspection of a series of “living specimens.” In future, then, the success of our medical societies will probably be in proportion to the degree in which they cultivate the social and practical sides of medicine, leaving the more highly technical subjects to be dealt with in the medical journals, a medium in every respect more suitable for their consideration.

WOMEN AND WORKING MEN MEMBERS OF HOSPITAL BOARDS.

GLASGOW is at present concerned over the question whether the Board of Management of her Royal Infirmary shall not be enlarged, and at the same time made available for the admission of women and working men representatives, elected by the general body of qualified contributors to the Hospital funds. As the number of managers in this instance is at present only ten, a nominal increase may not be undesirable, especially as a scheme of reconstruction and extension is in progress. At a general meeting of contributors, held last week, a unanimous resolution was adopted, with the agreement of the present managers, to the effect that women and working men should, as soon as possible, be rendered eligible for election. As the small size of the Board, as now constituted, appeared to its members to negative any idea of substituting ladies or working men for any of the present number, the only plan which recommended itself to the meeting was to agree to wait until the charter of incorporation had been altered, so as to allow of an increase in this number. This necessary alteration is to be made as soon as possible. A few years ago the Royal

Infirmary of Edinburgh admitted two ladies on its Board despite a considerable amount of opposition to such an action; the result has been most satisfactory. The Western Infirmary of Glasgow has had a similar experience. There is a great difference between a Board of ladies, with perhaps a man or two, and one consisting chiefly of men, but with one or two ladies on it. A female leaven is often beneficial and desirable in the management loaf; a female loaf, even with a male leaven, is generally disturbing. It has been often said that when a man applies himself to do any kind of work usually regarded as appertaining to womankind, he does it just as well, or even better, than the gentler sex; but it stands to reason that men who conduct the affairs of a large hospital, with all the manifold details, may often be advised by woman and guided in the proper paths, concerning many matters more familiarly known to her than to them. When details as to clothing, food, as regards female servants or nurses, come up before the Board for supervision, feminine experience is of value; while communications between the Board and the female officials of the house are rendered more facile and satisfactory. The advantage to be gained by the compulsory inclusion of working men in a Board seems not to be so clear. The conduct of the affairs of any large institution in a proper manner is best carried out by those who have had former experience in the management of large undertakings, be they commercial or professional. The matters which come up for discussion require the broadest handling. Between the patients, the officials, the contributors, and the conflicting interests (usually supposititious) the medical staff have to be impartially considered. It is open to question whether the demand for working men representatives is not based upon the popular opinion that hospitals only exist for the immediate benefit of those admitted, not for the furtherance of medical science and skill, or for the training of those who will hereafter be called upon to treat them or their children. It is wonderful how widespread the idea is among the working classes that hospital treatment is a right, not a charity, although the hospital be supported by voluntary contributions. Regarded in this light the patients naturally conceive that any use made of their symptoms for the furtherance of medical knowledge, or for the education of their future medical attendants, savours of injustice; forgetting that, without students, the members of the visiting staff would not be drawn from the highest ranks of the profession, the hospital probably would not be able to support so many beds, and the treatment given them would not be synonymous with the best obtainable even by the rich. The medical staff give their services gratis in return for experience gained; the patients should be ready to meet them half-way; recognising the good done to the community by the training of future doctors and by the opportunities afforded to the staff for the discovery of the true nature of disease, and the means best adapted to cure it.

Notes on Current Topics.

The Dublin Conjoint Examinations.

THE report of the results of the Autumn examinations has just been presented by the Conjoint Committee. It deals with the examinations, which commenced on October 2nd, and we do not observe that it contains, as it ought, an apology for the delay of nearly three months in presenting it. A fortnight ought to be abundantly sufficient time to compile an analysis of passes and rejections, and to have it printed, and we submit that the system of holding back the figures is altogether unnecessary and objectionable. The total number of candidates examined shows a serious falling off from the number for the similar examination of 1898:—129 for 1899 as against 152 the previous year. The rejection percentage varied between 38·5 for the first examination to 62·5 for the third examination, and the average of all the four examinations was 45·8. For the first examination we note that every candidate who presented himself in anatomy passed, and the Committee expresses the opinion that the standard of answering in that subject is not sufficiently high. At the second examination the "mortality" was very great, the percentage of rejections being 62·5, a result which manifestly arose from the examiners in physiology having, as usual, run riot in their marking. For 28 candidates passed 23 were rejected by them. For the third and fourth examinations the figures are almost equally discouraging. In medicine, for 24 passed 18 were rejected, and in surgery, for 19 passed 14 were rejected. The Committee favours us with the stereotyped statement that "the various portions of the examinations were, in general, satisfactorily carried out and were conducted strictly in accordance with the regulations"—an opinion which certainly is not shared by either teachers or students as regards the physiology and histology subjects. The attention of the Committee of Management has been more than once called to this matter by the College of Surgeons, but, so far as we know without eliciting any more satisfying explanation than the repetition of this platitude. The preliminary examinations held by the same Committee show a more satisfactory result, although the number of candidates (101) was below that of last year (117). The entrants seem, however, to have been a better class than in 1898 for the rejection percentage was only 47·5 against 53·5. These examinations are now conducted by high class educationalists unconnected with the medical profession or with school or collegiate interests. It would be well if as much could be said of the University examinations, for whose benefit the General Medical Council is seeking to extinguish the Dublin Preliminary.

A PASTEUR Institute was opened in Lyons at the beginning of the year. This makes the eighteenth institution of the kind in France.

The Death-rate of Liverpool.

THE City Council of Liverpool are disturbed at the high mortality-rate which is now prevalent in the town, and there is reason for their anxiety, inasmuch as the death-rate is 50 per cent. higher than was the case at the corresponding period of last year. Investigation into the various causes of death shows that there was no special malady answerable for this great increase. Although an influenza epidemic had claimed many victims, the returns nevertheless indicated that only one-fifth of the increase could be attributed to this disease. It has, therefore, been pertinently asked, if only this small proportion of the increase could be assigned to influenza, how was the remaining percentage of the augmented death-rate to be accounted for? No satisfactory reply to this query has, so far, been forthcoming; nevertheless it would be interesting to have some information upon the subject, for it is generally admitted that the Liverpool Corporation spare no expense in perfecting the sanitary condition of the town, and, moreover, they have an excellent medical officer of health in Dr. Hope. Some attempt has been made to explain the high mortality-rate by attributing it in some degree to the particular class of people who make Liverpool their headquarters. It has been said that the town is the resort of the residuum of the working classes, who take shelter within its confines when they cannot obtain work elsewhere. But it does not appear that the death-rate is especially high among the classes in question, and therefore this explanation does not seem to us to be adequate, at all events so far as Liverpool is concerned. Whatever, then, may be the causes of the high mortality-rate in Liverpool, it is clear that some faults must exist in the sanitation of the town which require remedying; however, it is not to be supposed that the Liverpool Corporation will fail in their duty to make good the defects as soon as they have been shown what these defects are.

Colour Blindness in Negroes.

It is commonly believed that impaired colour sense is less frequent among the black than among the white races, and in support thereof, in a recent examination of two thousand negroes employed upon a railway, Dr. Allport, of Chicago, was able to show that no case of the kind was discovered. But in a limited number of negroes examined by Dr. Joy Jeffries two per cent. of colour blindness was found. Again, Dr. Burnett, as the result of the examination of three thousand negro school children, showed that about one-and-a-half per cent. of the boys, and about one-tenth per cent. of the girls, had impairment of the colour vision. The relative frequency of defective colour sight between white and black races is not without interest in connection with the assertion that within historical times there has been an increase in the acuity of colour perception. It has been argued, however, that this theory is not borne out, in view of the infrequency of any defect in this regard among negroes. In other words, if good colour perception be acquired as the result of prolonged civilisation, it is

difficult to see how this faculty should be so well developed in a race like negroes, whose ancestry could not be included among the civilised races of the world. Possibly, however, the development of the colour sense among negroes has been acquired as the result of their natural environment. Just in the same way as the special senses are very largely developed in certain nomadic Indian tribes, so it may be that the possession of good colour vision was found to be a necessary adjunct to the habits of the negro race.

Veterinarians and Surgeons.

In the statement issued by the Government during the past week bearing on the organisation of the Yeomanry Corps for service in South Africa there is one point which cannot fail to attract the attention of medical men, viz., the emoluments offered to the surgeons in charge of that force is put at the not exorbitant figure of £200 per annum, whereas the remuneration provided for the veterinarians amounts to £250. Why this difference? Is it that there is less competition in that department of medical practice, or is it simply because the services of veterinary surgeons are valued more highly than those who merely tend the wounded and sick soldiers? The matter is so extraordinary that we shall be grateful to any member of Parliament who will make it the subject of a question in the House.

The Fatalities of Sport.

THE occurrence of a second fatal mishap in connection with a boxing match within a few months of the first suggests the propriety of revising the rules under which this time-honoured sport is at present carried on. Unfortunate as are these occurrences we cannot admit that they of themselves justify an indictment of boxing. Similar accidents are regrettably frequent in the cricket field and as the result of collisions at football, indeed every sport entailing violent exercise claims its victims. We do not quite grasp the reason for the difference in the treatment of these cases by the police. We have never heard of a footballer being brought before the magistrate on a charge of homicide by imprudence, and unless the inquest reveals special circumstances we fail to see what good can accrue from prosecuting the boxer who has been unfortunate enough to kill his adversary. It is impossible to regard these proceedings as anything else than a judicial farce, because no British jury could be hectored or cajoled into finding the accused guilty of anything calling for punishment. Nevertheless, since experience has proved the possibility of administering deadly blows with the light gloves in use at boxing matches, the managers of the National Sporting Club will be well advised in revising their rules in regard to this point, if only to disarm hostile criticism. At the same time no amount of padding will ever completely eliminate the risk of a fractured skull or a broken or dislocated neck, since, apart from the force of the impact, there must always remain the danger of violent collision with the floor. A certain section

of the public view this particular sport with frank misgiving on account of its resemblance to real fighting, a display of brute force which they find aesthetically objectionable. but fencing is another instance of the same thing, and fatal accidents are not unknown in the *salle d'armes* as the result of the defensive button dropping off unperceived. We must accept these risks if we are to derive the benefit of such sports in developing the body, and in this respect they stand on the same footing as the loss of life which is associated with every considerable industrial undertaking.

What is a Common Lodging House?

The judges of the Queen's Bench Division had before them last week the case of the Emigrants' and Working Men's Homes Association, on an appeal by the London County Council against the refusal of a metropolitan police magistrate to find that a particular building ought to be registered as a common lodging house. They arrived at the decision that the building in question could not be distinguished from the Salvation Army shelters which had previously been assimilated to common lodging houses, and they consequently decided that the law must apply to them as such. Any other view would have been very regrettable from the point of view of public hygiene. The principal object of the regulations affecting these buildings is to protect the public against the spread of infectious disease and to prevent overcrowding, and, if such precautions are necessary in the one case they must logically be applied to every institution of a similar kind. The fact of their being carried on for a profit or on purely charitable lines is not, strictly speaking, *ad rem*, for the recipients of charitable assistance are as much entitled to protection as any other class of the population. Moreover, we do not understand exactly why the managers of these institutions so obstinately resist the moderate amount of interference which the regulations comport. It may entail some trifling additional expense, but in view of the advantages to the inmates and to the public of the enforcement of certain elementary sanitary precautions, their opposition savours of imbecility. We take it that this decision settles this vexed question once and for all, so that in future philanthropists who contemplate the organisation of these shelters will do so with these regulations clearly before them.

Glaucoma following the Instillation of a Mydriatic.

THE case of glaucoma recorded at the last meeting of the Ophthalmological Society as having occurred after an instillation of a four-grain solution of homatrophine, again emphasises the risks associated with the use of mydriatics in elderly persons. The golden rule is to avoid as much as possible the use of such drugs after patients have reached the age of thirty. But where dilatation of the pupil is essential to a complete examination of an eye, it is always best in middle-aged people to neutralise the effects of a mydriatic afterwards by means of eserine. This is

really the only means by which accidents of the kind can be avoided, for it is not possible in every case to say whether sudden increased tension will not ensue after a mydriatic has been used. The importance of the matter is that advancing hypermetropia is commonly a premonitory symptom of glaucoma, and it is in these cases that the danger especially lies; an instillation of a mydriatic under such circumstances might just be sufficient to upset the balance of the tension, leading to the rapid development of the disease. But there is another aspect of the matter, which also impels caution in these cases. Patients are naturally disposed to remember that until the "doctor" ordered some drops for their eyes their sight was good, but as soon as the drops were used the sight began to fail, acute pain to supervene, and ultimately the vision became entirely lost. Then in consequence reputations are apt to suffer injury, for the facts are indisputable and there is no possibility of explaining them away. Such cases belong to the "calamities of surgery," since it is not always possible, owing to the negligence of the patients and other causes, for the mischief done to be made good.

The Pharmaceutical Preliminary Examination.

It is officially announced that the forthcoming preliminary examination of the Pharmaceutical Society of England will be the last to be held, and its place will subsequently be taken by scholastic examinations, conducted by universities and other examining bodies in the United Kingdom. The last examination will take place on July 10th.

Is the Plague in England?

It has been suggested by a correspondent of THE MEDICAL PRESS AND CIRCULAR that the plague may be really in our midst in an unsuspected form. While the facts on which this surmise is founded are as yet too scanty to warrant any definite conclusion, they are nevertheless sufficient to demand scientific investigation. Briefly, some six or eight months ago there appeared at Southampton a disease which attacked dogs, and proved so fatal and infectious that in a short space of time the town was practically cleared of its canine population. Since then the disease, which appears to be of a highly specific nature, has spread slowly but surely over many parts of the United Kingdom. Deaths from this epidemic are occurring at the present time in London, and veterinary surgeons are now everywhere alert as to its occurrence. The points suggestive of plague are the invasion of a seaport town, where dogs might easily become infected through ship rats, and the fatal nature and the high degree of infectiousness of the malady. On the other hand, it is hardly likely that if plague had really attacked so widely domesticated an animal, that the contagion would not quickly have been communicated to man. On the whole, the theory of plague, although ingenious and even remotely possible, cannot be regarded as probable. At the same time it would be of great

interest to learn from the veterinary profession what are the facts about this canine zymotic, and whether any scientific investigation has been made as to the nature, both chemically and bacteriologically. There can be no doubt that the communicable diseases of the lower animals have an enormous influence upon the present prevalence and the future prevention of preventible diseases.

Should Hospital Post-Mortems be Compulsory?

THE legal position of hospital medical officers with regard to post-mortem examinations is somewhat complicated. There is nothing illegal in such an examination provided the rights of other persons and of the coroner be not interfered with. When an inquest is to be held the post-mortem may be ordered by the coroner, and no one may anticipate that decision. In other cases the medical officer may safely proceed to make a *sectio cadaveris* if he have the consent of the friends of the deceased. From a strictly legal point of view the possession of the body is vested in the executors or administrators, but in practice that priority is waived in favour of relatives. Where a post-mortem is performed on a body awaiting inquest or without the consent of relatives the step is taken entirely at the risk of the person who performs it. In many medical charities it is made a condition of admission that the authorities reserve the right of holding a post-mortem examination in case of death. In the Poor-law infirmaries the consent of relatives is an invariable condition. There can be no doubt that by refusal an immense amount of valuable clinical material is lost to the medical profession. So far as one can see, there is no particular reason why the legislature should not empower the medical officers of Poor-law infirmaries to conduct such examinations wherever they may deem such a proceeding desirable. It is hardly needful to remark that any contract entered upon by a man as to the disposal of his body after death is invalid at law, so that a man who gives directions that he shall be dissected or burnt cannot be sure that his wishes will be carried out.

The Prophylaxis of Syphilis.

DR. CHARLES DRYSDALE calls attention to Professor Fournier's recently expressed opinion that systematic inspection of prostitutes as a means of checking the spread of syphilis is a failure. The Professor concludes that the "English" system of treating such cases in hospital is in every respect preferable. The weak point in the argument is that there is no English system of the kind, if we except the Lock Hospital, which can reach but the fringe of infection. It is indeed a lamentable thing that in practically all English hospitals it is the rule not to admit cases of primary syphilis. It has often been our experience that a girl, on being warned of the consequences to others of her diseased condition, has forthwith expressed her willingness to enter the hospital for treatment, only to be met with the reply that such cases were not eligible. Under

these circumstances their only resource is to continue to ply their wretched calling. The fact is that the lay governors of hospitals are largely recruited from among ministers of religion who evince an indisposition to do anything which may have for consequence to lessen the risks run by the incontinent. They are deaf to the argument that the innocent have in great measure to bear the brunt of the erring one's misconduct and they maintain the veto. If we were really serious in the wish to do our best to stamp out this hideous disease every general hospital would have its special ward for syphilis. The proportion of diseased prostitutes who would refuse to avail themselves of the opportunity for treatment would be small indeed, and this system of voluntary notification would probably do more lasting good than any detective and punitive system yet suggested.

Public Lavatory Accommodation.

DURING recent years a great deal has been done in the way of increased public lavatory accommodation in almost every large town in the United Kingdom. No doubt much of the zeal may be traced to the discovery by local authorities that a modern, well-fitted establishment was a sound commercial investment. Another reason was doubtless due to the construction of such places underground, in space that would otherwise have been valueless to the public. Perhaps one of the most sensible developments has been the provision of accommodation for both sexes, although there can be no doubt whatever that the wants of women in that direction are still inadequately met all over the country. The crowded condition of public lavatories in our great towns, especially in the dinner hour and when work is over, makes one wonder what must have been the state of affairs before modern extensions had taken place. Another aspect of the case is the need of increased free accommodation, which is clearly enough demanded in poor districts. Indeed, the recognition of such a requirement should form one of the earliest efforts of an enlightened public health administration. Curiously enough, the important question has never been seriously taken in hand by the London County Council, but some day we may expect that body to turn some of its ubiquitous energies in this much-needed direction.

Amateur Plumbing.

IT is hardly credible what gross travesties of sanitary plumbing are often introduced into good-class houses by builders and workmen who are not acquainted with the principles of practical sanitation. The worst cases are to be found in large country houses, where repairs or reconstruction have been confided to some local wiseacre, who may be shrewd enough in many other ways to have established a reputation as jack-of-all-trades. Woe betide the household whose sanitary safety is confided to such a man. The results are often written large in the sore throats, the anæmia, the chronic ill-health of inmates, or more acutely in outbreaks of diphtheria,

diarrhœa, or typhoid fever among the inmates. The unfortunate owner of the house, who has probably paid a large sum to have everything "thoroughly overhauled," and brought up to the best modern requirements, at length, has his suspicions aroused, perhaps on the prompting of his medical attendant, and thereupon consults an expert. Then comes the disillusion as each detail of defective plumbing, and of sanitary ignorance is laid bare in the fool's paradise. Water cisterns are found with overflows opening into closet pipes, and affording a supply in common to closet and to drinking service; unventilated and leaking soil pipes, leading without traps into outside drains; sewer ventilators opening close to windows; fixed washing basins with discharge pipes passing untrapped into soil pipes; drain pipes with loose joints running under the house, and so on *ad infinitum*. The worst feature is, when, as sometimes happens, this criminally bad workmanship is carried out under the direction of an architect. The truth of the matter is that no amount of natural cleverness can replace systematic practical training in sanitary matters.

The New Registrar-General.

THE appointment of Mr. Reginald Macleod, C.B., as Registrar-General, in the place of Sir Brydges Henniker, who retires under the age limit, has been approved by the Queen, so that one more opportunity has been lost of nominating a medical man to this important office. In a recent number we drew attention to the advantages which would attend the presence of a medical man at the head of this department. We pointed out that a medical training is indispensable for the proper appreciation of the value of many of the items of which statistics are made up. As matters stand at present, the scientific importance of these statistics is diminished in consequence of the impossibility in many cases of ensuring that the units of comparison are strictly comparable, and this is especially the case in regard to the certificates of the cause of death. It seems to be assumed in Government circles that a professional training is inconsistent with business and administrative aptitudes, an assumption which experience has shown to be devoid of foundation.

Filtration and Health.

THE importance of the water supply in respect of the incidence of such diseases as typhoid fever is too well known for it to be necessary to insist thereon but, as sundry painful experiences of recent date have shown, the lesson is one which is not yet fully appreciated. The last report of the Massachusetts Board of Health comprises a statement which affords an excellent object lesson. In the city of Lawrence the mortality from enteric fever averaged between 47 and 69, falling to 39 in 1893. In the latter half of that year filtration beds were constructed and the mortality at once fell to 24. The diminution has been maintained ever since, the number of deaths in 1898 not exceeding 8, equal to 1.39 per 10,000 of inhabitants.

Gonorrhœa a Cure for Inebriety.

A CORRESPONDENT writes:—One of the best cures I am acquainted with for habitual excessive indulgence in alcoholic beverages is the gonococcus. This is not a serum treatment because, for the purpose in view, the effects of the organism must wreak themselves on the urethra. I have, over and over again, failed to induce patients with this particular weakness to control their appetite for alcohol. Promises of reform were made only to be broken. Then it has happened that they contracted gonorrhœa, and forthwith, without any pressure, for three long months at least, they have foregone their tippie, and have recovered the strength of will which they had lost. I could point to a number of cases in which the drunkard's progress has been summarily arrested by an intercurrent attack of gonorrhœa with the most satisfactory results in respect of his after life. It is open to question whether, in refractory cases this treatment might not offer an alternative to seclusion in a home for inebriates.

The Hull Small-Pox Bill.

THE inhabitants of Hull are now in a position to appreciate the importance of taking steps to prevent such things as epidemics of small-pox. The recent outbreak, which is now approaching extinction, has cost the borough no less than £21,056, a sum which will entail additional rates to the tune of eightpence in the pound. But it must be borne in mind that this sum, large though it be, does not even approximately represent the financial loss to the citizens of the stricken town. To it must be added the loss of hundreds of pounds sterling which the epidemic must have caused in business, to say nothing of the loss of life and health which such a visitation entails. We trust the lesson will not be thrown away on the authorities of other towns and cities where the protective value of vaccination has in the past been deliberately rejected.

Quack Medicine Advertisements.

THE Chairman of the Edinburgh Public Health Committee has recently made some strong, but not at all too strong, observations on this subject. "There were few more discreditable instances of man's inhumanity to man than the professions made by vendors of various kinds of medicines to heal troubles which they could not possibly alleviate in the slightest degree. Poor people were not merely swindled by these medicines, but in many instances, after using them, were brought to a worse condition than before, and sometimes even their lives were endangered. So-called religious papers, and papers which professed to exist for the purpose of promoting the social well-being of the people, he found to be the worst offenders by the publicity they gave to quack medicines. Some of the medicines offered as priceless were absolutely worthless, and worse than worthless. Pills had been found to be made of ginger, soup, and aloes of the coarsest description. The ginger and aloes were held together by the worst of soap, and out of that concoction was made a box of

pills which were said to be a cure for almost every malady that afflicted the human being. It was said that some papers could not live without advertisements of this description, but such papers ought rather to refuse to exist than be means of not only imposing on people, but helping others to make homicides of themselves."

"Lennox" of the "Echo."

ALFRED MELLETT PEIRSON, otherwise known as "Lennox," has had to "apologise fully, freely, and unreservedly," for publishing a libel against Dr. James Griffin, of Banbury. The use by this individual of the pseudonym "Lennox" has been the occasion of considerable annoyance to a well-known member of the profession practising aural surgery. But in view of the fact that in affidavit Peirson gives his first names as those of Alfred Mellett it is matter for further comment that his name is to be found in three different places in Kelly's Post-office Directory as one of the two aurists and again as an aural specialist, wherein the name is given Lennox Peirson, as if the first were not a pseudonym but his Christian name.

The Coming Army Medical Competitive.

It is stated that the entries for the coming competitive, for which thirty vacancies were advertised, only number twenty-five. This is a very serious conditions of affairs, if "my military advisers" could only see it, because the absolute necessities of the Service demand a reinforcement of the Royal Medical Corps by at least a hundred officers. We are, however, not so sanguine as to hope that Pall Mall or Whitehall will realise this fact.

THE dangerous use of some of the so-called "pick-me-ups," was exemplified a few days ago in the case of a medical practitioner at Sheffield. He had hurriedly swallowed an overdose of one containing strychnine, and was shortly afterwards found violently convulsed, death supervening in a few minutes.

PERSONAL.

DR. W. PASTEUR, F.R.C.P. Lond., Assistant Physician and Dean of the Medical School, Middlesex Hospital, has been elected physician to the hospital.

PROFESSOR CLIFFORD ALBUTT has been elected as the next Harveian Orator, Dr. Archibald Garrod, as Bradshaw Lecturer, and Dr. John Sykes as Milroy Lecturer at the Royal College of Physicians, London.

SIR PHILIP SMYLY has been re-elected by the Council of the Royal College of Surgeons as representative of the College in the General Medical Council for one year from this date.

HER Royal Highness Princess Beatrice will to-day open the new wings of the Royal South Hants Infirmary. The sanction of the Queen is to be asked for the change of designation from Royal Infirmary to Royal Hospital.

THE representative of the English Local Government Board appointed to serve on the Commission of Inquiry as to Dublin Sanitation is Dr. Theodore Thompson, one of the medical inspectors under that Board. The roll of commissioners is now complete.

MR. LENNOX BROWNE has retired from the active staff of the Central London Throat and Ear Hospital, but will continue to be identified with the institution as consulting surgeon. His colleagues on the committee and medical staff have, in the past week, presented him with an illuminated address recording "their high appreciation of the energy, devotion, and skill which he has exercised on behalf the institution since its foundation in 1874," accompanying the address with a gift of old English furniture for use in his country house.

ON Thursday last, Sir William Thomson left Dublin for Africa, and he was followed on Friday by the other officers and men of the Iveagh Field Hospital, who had been formally inspected by the Officer commanding the Dublin garrison, on the previous day. The send-off of both Sir William Thomson and his force was most enthusiastic, the railway station and the quays being crowded on both occasions by a cheering mass of the public and of the profession. Sir William has proceeded by the ordinary mail steamer from Southampton in order that he may be at Cape Town some days before his expedition arrives. They were to leave London in a day or two.

LIEUTENANT-COLONEL SLOGGETT, R.A.M.C., who has accepted the appointment of Military-Director-in-Chief and Principal Medical Officer to the Imperial Yeomanry Hospital, and has, at the request of the committee, been specially recalled by the War Office authorities from Egypt, has been twice specially promoted for distinguished service in the field. It is related of him that at the battle of Khartum he was dangerously wounded; indeed his body had been placed with others for burial, when by a happy incident someone noticed a slight sign of life. The ball entered his breast and came out under the shoulder blade, and his recovery was recorded as one of the most marvellous in the annals of surgery.

Correspondence.

We do not hold ourselves responsible for the opinions of our correspondents.

WORKMEN'S COMPENSATION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Your leading article of last week on this subject opens up a very important but withal delicate question. Evidently, unless the Act is worded so as expressly to exclude the secondary consequences of an injury, these must be held to form an integral part of the damage. It has over and over again been held that a policy of insurance against accident covers blood poisoning *inter alia*, and it is not obvious why workmen's compensation should be calculated on a different basis.

The assertion that only broken-down or otherwise unhealthy individuals fall victims to blood-poisoning is a pure assumption without scientific support. If the writer of the article were inoculated with an active culture of some pyogenic organism, the chances are that, whatever his state of health may be, he would

suffer severely, and this experiment is one which is constantly being enacted in daily life. Such an inoculation, when the result of an accident, is as "accidental" as a broken leg, and once again there is no obvious reason why it should be regarded as anything different.

At the same time there may be special circumstances which might conceivably exclude the workman from the benefits of the Act. If, for instance, he accidentally scratched his hand with his scarf-pin while at work and contracted blood poisoning, that might be construed as occurring outside his calling, but a carpenter who, in hauling planks, runs a splinter into his finger, is very legitimately entitled to compensation.

Employers may be trusted to take care of themselves, indeed they have already done so by the aid of insurance companies, moreover they have no status from a medical point of view.

I am, Sir, yours truly,

M. O. H.

MINUTE DISPENSING.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—In reference to the statements and correspondence recently appearing in your journal, and where you state that pharmacists are incompetent to compound prescriptions containing minute quantities of potent drugs, I am requested by the Dublin Chemists' Federation to forward to you the following resolution passed at the last meeting on the 26th ult. :—

"The Dublin Chemists' Federation protests against the statement made by the MEDICAL PRESS & CIRCULAR that pharmacists are incapable of dispensing minute doses of potent drugs. On the contrary, they confidently assert that chemists can compound such more accurately than wholesale pill and tablet makers. Such prescriptions as those referred to are the daily work of ordinary pharmacists."

I am, Sir, yours truly,

J. SMITH, Hon. Sec.

Dublin Chemists' Federation, Dublin,
February 1st, 1900.

Our observations on this subject have been entirely misinterpreted, and we regret to observe that they seem to have given offence to the chemists. What we did say was that "We should like to see the practitioner who would venture to hand to a patient from the country a prescription for half a dozen pills containing, each of them, say, a thirteenth of a grain of strychnine, or phosphorus, or strophanthin, or cocaine, or atropine. The tablet makers can grind a drachm or an ounce of strychnia into a multitude of tablets, but the individual dispenser cannot be certain of effecting the same subdivision for half-a-dozen pills." We do not doubt that there are many skilled and punctiliously careful compounders who could do so, but the provincial prescriber can rarely send his patient to them, and we repeat that it would be very risky to entrust such minute dispensing to the average country chemist or his shop assistant.

The Medical Officer Frauds.

A MAN called Edward Hopwood was recently sentenced at Birmingham Quarter Sessions to fifteen months' imprisonment for attempting to obtain £100 from Dr. M. Duncan Laurie. Hopwood represented that he was commissioned by an American Insurance Company to appoint medical officers in the chief towns of Great Britain at a salary of £100 on their agreeing to take shares for £100. He offered Dr. Laurie the appointment, and asked for £100 down, but the doctor was suspicious, and the police were communicated with, the result being that it was found that the company did not exist.

Obituary.

SIR THOMAS GRAINGER STEWART, M.D. EDIN.,
M.D. DUBLIN, AND R.U.I. (*honoris causa*); F.R.C.P. EDIN.,
LL.D., F.R.S.E., HON. F.R.C.P.I.

We regret to announce the death, on the morning of Saturday last, of Sir Thomas Grainger Stewart, Professor of Practice of Physic and of Clinical Medicine in the University of Edinburgh. Last summer we had occasion to refer to the fact of his serious illness, and again this winter to his slow and doubtful convalescence; but his death occurred unexpectedly at the end, for he had improved so much a short time before as to be able to take carriage exercise. The actual cause of death appears to have been simple failure of the heart, the sequel to a somewhat prolonged affection of that organ, originally, we believe, of influenzal origin.

Sir Thomas Grainger Stewart at the time of his death was 63 years of age, having been born in 1837 in Edinburgh. Educated first at the Edinburgh High School, he next studied medicine at the University of his native city, and took his degree when 21. After a stay in Germany, spent in study in Berlin, Prague, and Vienna, he was appointed house physician in the Royal Infirmary, Edinburgh, shortly to be advanced to the post of pathologist. While occupying this position he engaged in work upon renal pathology, which led later to the publication of his well-known treatise upon "Bright's Disease of the Kidneys."

At this time Dr. Grainger Stewart lectured in the Extra-mural School of Medicine on Pathology. Later he was appointed one of the assistant physicians to the Infirmary, and in 1873 commenced to lecture on medicine in the Extra-mural School, only to be transferred in the same year to fill the vacancy caused by the death of Professor Laycock in the Chair of Practice of Physic of the University, a chair which he filled up to the time of his death. Many honours were conferred on him in after life. He was made one of the Physicians in Ordinary to the Queen in Scotland; Aberdeen University awarded him the degree of LL.D.; Dublin gave him two M.D. degrees and a Fellowship, *honoris causa*, as did Philadelphia; his own college in Edinburgh elected him its President some few years ago; while in 1898 he filled the post of annual president of the British Medical Association at its Edinburgh meeting.

Sir Thomas Grainger Stewart as a professor was very successful. He lectured clearly, pleasantly and instructively. To him had been given the gift of words, and felicitous expression. No need for him to pause in search of appropriate terms in which to clothe his meaning. His words exactly and happily expressed what his mind conceived. Interesting his lectures always were, frequently enlivened with touches of a pawky Scotch humour, of which he had no small share. His gift of language stood him in good stead when called upon to deliver an address, and made him one of the best of after-dinner speakers. To these were added a fine figure and a commanding presence.

His chief contributions to medical literature comprise "A Practical Treatise upon Bright's Diseases of the Kidney," of which a second edition appeared in 1871; "Clinical Lectures upon Important Symptoms: 1. Giddiness (two editions), 2. Albuminuria;" "An Introduction to Diseases of the Nervous System;" along with a number of shorter communications and addresses. But Sir Thomas Grainger Stewart possessed other literary gifts, and quite recently published a dramatic play in blank verse, "The Good Regent," and dealing with the days of Mary, Queen of Scots, which was received very favourably by the public.

In private life he was a most agreeable host and companion, a zealous Free Churchman, and in politics a strong Gladstonian.

The University of Edinburgh has thus to deplore the deaths of two medical professors within a year; last year of Professor Rutherford, now of the Professor of the Practice of Physic; the profession in Edinburgh has lost four outstanding members, only one of whom had passed the life limit of the Psalmist within the same period; Sir J. Struthers and Dr. John Duncan, in addition to the first two.

[The following further notes have been furnished to us by a former University class assistant of the late Sir Thomas.]

Sir Thomas Grainger Stewart was an Edinburgh man born and bred. He was educated at the University of Edinburgh, and although it is as a clinician that his name will be remembered, it may be of interest to some to know that he made his reputation first as a pathologist. For some time he was Pathologist to the Edinburgh Royal Infirmary and Lecturer on Pathology in the Edinburgh Royal College of Surgeons. That his abilities as an original investigator in that department of science were of a high order is evidenced by his classic work on diseases of the kidneys, a subject which, prior to his researches, was in this country at least a "*terra incognita*," and when the Chair of Pathology in the University of Edinburgh became vacant, Dr. Grainger Stewart was one of the strongest rivals of the late Professor Hughes-Bennett, who obtained the appointment.

But a man of his marvellous ability for imparting knowledge could not long be left in the background, and accordingly, in 1873, when the Chair of Medicine became vacant, Dr. Grainger Stewart was appointed. Since then, as a teacher of generations of Edinburgh students, his reputation has added lustre to the great school of which he was so brilliant a representative.

This is no place to catalogue the long list of his scientific and medical achievements. Suffice it to say that he was in no sense a one-sided man, even within the boundaries of his own profession. He was a pioneer not only in the study of renal affections, but also in modern neurology, his writings on peripheral neuritis being the earliest in this country to direct attention to that disease.

But although his writings are a model of concise statement and of elegant diction, it is not merely as a writer and original investigator that he will be longest remembered. As a lecturer and clinical teacher he has left his mark most deeply on the Edinburgh school. He was a polished and fluent orator of outstanding ability, and in his lucidity and power of explaining the most

complicated subjects he was unsurpassed. His lectures were more than the mere compression of a diligent reader, they were illuminated by a wealth of clinical experience and brightened by many an apt tale.

His genial and courtly manner, his tact, his *savoir faire*, were an object-lesson to all who were privileged to know him. To those qualities, moreover, was added a native shrewdness and a knowledge of men and things which made him a man of weight in any meeting, however cosmopolitan. The able way in which he filled the Presidential Chair at the Edinburgh meeting of the British Medical Association in 1898 was the subject of admiration to all who were at that gathering, and his mellow oratory was heard to similar advantage in Berlin at the last International Congress on Tuberculosis.

The following anecdote exemplifies his ready wit:—At a German congress a famous "renal" physician remarked to Sir T. Grainger Stewart: "Wir beide Nieren-artzensollten zusammen sitzen" (We two kidney specialists ought to sit together). Sir T. Grainger Stewart promptly replied:—"Also, lassen wir rückwärts bleiben" (Well then, let us keep close to the Back).

His literary gifts were not confined to the medical and scientific press. A couple of years ago he published a long romantic poem on the subject of the Regent Moray, which evinced a poetic vein of no mean order.

His presidency of the Edinburgh Royal College of Physicians, his appointment as physician to the Queen, his subsequent knighthood, and the various honours which were showered upon him by learned bodies at home and abroad, all those were but the well deserved rewards of a man whose memory will linger long, in the heart of many a friend and pupil in every quarter of the globe

BERNARD EDWARD BRODHURST, F.R.C.S.

THE death of Mr. B. E. Brodhurst removes from our midst one whose name had, for many years, been closely and honourably associated with progress in orthopaedic surgery. His claims to distinction in this department were fully recognised all over the world, and Mr. Brodhurst was correspondent and member of all the best-known orthopaedic societies.

Mr. Brodhurst took his member's diploma of the Royal College of Surgeons of England as long ago as 1844, becoming a Fellow in 1859. He was a copious writer on orthopaedic subjects, and in years gone by his contributions figured largely in the transactions of the principal metropolitan societies.

Among his works we may refer in particular to the well-known treatise on "Curvature in Diseases of the Spine," "Club Foot and Analogous Deformities," one on "Ankylosis," and "Lectures on Orthopaedic Surgery."

Mr. Brodhurst filled the post of surgeon to the Royal Orthopaedic Hospital and Royal Hospital for Incurables, also to the Belgrave Hospital for Children, and for many years he was attached to St. George's Hospital as surgeon and lecturer on orthopaedic surgery.

FRANCIS CHARLEWOOD TURNER, M.D., F.R.C.P.

WE regret to have to record the death at a comparatively young age of Dr. Francis Charlewood Turner, Physician to the London Hospital and to the North-Eastern Hospital for Children, &c.

Dr. Turner had, we are informed been in delicate health for some time past, but his death will come as a painful surprise to a large circle of appreciative friends.

Though not a very frequent speaker at medical societies of late years, Dr. Turner did a good deal of useful work, especially in relation to diseases affecting the circulatory apparatus the results whereof are embodied in contributions to various congresses and society transactions.

MR. WM. ADAMS, F.R.C.S.

WE regret to announce the death on Saturday last (the morning of his 80th birthday), from bronchitis and congestion of the lungs, of this well-known orthopaedic surgeon. He had retired from the active practice of his

profession some years, but up to within the last twelve months he was frequently called in consultation in severe and complicated cases. Mr. Adams was a voluminous writer on subjects connected with his specialty, and many of his works went into second editions. He was author of the Jacksonian Prize Essay of the Royal College of Surgeons, England, in 1864, entitled "Club-foot, its Causes, Pathology, and Treatment." The Lettsomian Lectures on "Rheumatic and Strumous Diseases of the Joints," and Lectures on "The Principles of Treatment Applicable to Contractions and Deformities," appeared first in the columns of this journal and were subsequently reprinted in book form. He occupied the presidential chair of the Medical Society of London some few years since, and at the time of his decease was consulting surgeon to the Great Northern Central Hospital, the National Hospital for the Paralytic, and the National Orthopaedic Hospital. Mr. Adams possessed a singularly amiable and kindly nature, which attached him to a wide circle of friends both in and out of the profession, all of whom will be saddened at the knowledge of his death.

SIR WILLIAM MILLER, M.B., J.P., LONDONDERRY.

A MUCH-RESPECTED citizen of Londonderry passed away on the 28th ult., in the person of Sir William Miller, M.B., J.P. He had been suffering from an attack of influenza, and had partly recovered, when some complications set in. He occupied a prominent place in the political and social life of Londonderry for more than forty years past. He was a magistrate of the city and also of the County Derry, a grand juror of the county, and a member of the City Corporation; he filled the office of chief magistrate on two occasions. Sir William was the second son of the late Joseph Ewing Miller, M.D., J.P., a gentleman who had held the office of Mayor of the City under the old Corporation before the Reform Act of 1840. Sir William gave a large portion of his time to the administration of the public affairs of the city and county, considering his professional engagements, and enjoyed a wide popularity. In the year 1875 he was first chosen mayor of the city during the vicereignty of the late Duke of Abercorn, and entertained that nobleman and the members of the Royal Agricultural Society during his first year of office. In the following year, having been re-elected mayor, he had conferred upon him the honour of knighthood, and was again chosen Chief Magistrate for the third year. Again he was elected mayor for the year 1888 and also for 1889. His professional appointments included that of surgeon to the county infirmary, medical officer of the prison, and surgeon-major of the militia. He had also an extensive private practice as a consulting doctor in the county as well as the city, where his advice was much sought after.

Medical News.

The Imperial Yeomanry Hospital Staff.

THE following is a list of the Medical Officers who have been appointed to the Imperial Yeomanry Hospital at the seat of war:—Lt.-Col. A. T. Sloggett, R.A.M.C., Military Commandant of the Imperial Yeomanry Hospital and Principal Medical Officer; Mr. Alfred Fripp, M.B., M.B.Lond., F.R.C.S.Eng., M.V.O., Chief Civilian Medical Officer; Dr. John Wichenford Washbourn, M.D.Lond., F.R.C.P.Lond., F.R.C.S.Eng.; Mr. Raymond Johnson, M.B., B.S.Lond., F.R.C.S.Eng.; Mr. F. Newland Pedley, F.R.C.S.Eng., L.D.S.; Mr. L. Vernon Cargill, F.R.C.S.Eng.; Mr. Hamilton A. Ballance, M.S., M.D.Lond., F.R.C.S.Eng.; Mr. William Turner, M.B., B.S.Lond., F.R.C.S.Eng.; Mr. John F. Hall Edwards, Surgeon-Radiographer and Photographer; Mr. Wallace C. G. Ashdowne, F.R.C.S.Eng.; Mr. J. S. Christopherson, M.D., B.C.Camb., F.R.C.S.Eng.; Dr. Andrew Elliot, M.D., C.M., Edin., D.P.H.; Dr. H. W. Saunders, F.R.C.S.Eng., M.B.Lond.; Mr. L. E. C. Handson, M.B., B.S.Lond.; Dr.

H. W. Bruce, M.D. Lond.; Mr. A. P. Parker, M.B., B.Ch. Oxon.; Mr. G. E. Richmond, M.B., B.S., B.Sc. Lond.; Mr. R. T. Fitzhugh, M.B. Lond., 1st F.R.C.S.; Mr. Barclay Black. The following will occupy the position of "Dressers" to the Surgical Staff:—Mr. J. Atkins, 1st M.B. Lond., 1st F.R.C.S.; Mr. A. Ayre Smith, 1st M.B. Durham, Surg. and Mid. Conj., C.A.S.W.; Mr. C. W. Brecks, M.B., C.M. Edin.; Mr. A. de V. Blathwayt; Mr. D. J. Greenfield, 1st M.B., 1st F.R.C.S.; Mr. M. B. Hay; Mr. A. Pearson, 1st M.B., 1st Arts Scholar; Mr. A. C. Ransford, 1st M.B.; Mr. Owen Richards, M.A. Oxon., 1st F.R.C.S., Fellow of New College; Mr. E. N. Thornton; Mr. J. G. Hamilton, Hon. Civilian Director of and Treasurer to the Imperial Yeomanry Hospital.

The Medical Sickness and Accident Society.

THE usual monthly meeting of the Executive Committee of the above Society was held on January 26th at 429, Strand, London, W.C. There were present Dr. de Havilland Hall, in the chair, Dr. J. B. Ball, Mr. J. Brindsey James, Dr. J. Pickett, Mr. F. S. Edwards, Dr. M. Greenwood, Dr. Alfred S. Gubb, Dr. W. K. Nowley Sibley, Dr. J. W. Hunt, Mr. William J. Stephens, Dr. F. J. Allen, and Mr. Edward Bartlett. The Committee examined special reports on all the cases of chronic sickness now on the books of the Society. There are now nearly twenty of such cases, and the evidence furnished to the Committee leaves little room for doubt that most of these members will continue to draw their sickness pay for the rest of their lives. The amount they receive varies from 150 guineas to 50 guineas per annum, and thus forms a very valuable provision. The influenza has once more greatly raised the number of sickness claims made upon the Medical Sickness and Accident Society, but during the year 1899 the total amount thus paid was less than that expected and provided for in the tables of contributions. Premiums and all particulars on application to Mr. F. Addiscott, secretary, Medical Sickness and Accident Society, 33, Chancery Lane, London, W.C.

Grants in Aid of Scientific Research in Dentistry.

THE Odontological Society of Great Britain places at the disposal of persons engaged in original research on dental subjects, grants of money, on certain specified conditions; to wit, such grant is not to be applied in payment of personal expenses except when specially authorised, and the results of such researches are not to be published elsewhere than in the *Transactions* without permission. Apparatus purchased with the grant is to remain the property of the Society, and, lastly, a report (or an *interim* report) is required to be furnished to the committee within a stated period of the grant. Further particulars can be obtained from the Secretary, H. Lloyd Williams, Esq., 2, Upper Wimpole Street, W.

Vital Statistics.

THE deaths registered last week in thirty-six great towns of England and Wales corresponded to an annual rate of 27.5 per 1,000 of their aggregate population, which is estimated at 12,786,832 persons in the middle of this year. The deaths registered in each of the last four weeks in the several towns, alphabetically arranged, corresponded to the following annual rates per 1,000:—

Birkenhead 14, Birmingham 27, Blackburn 23, Bolton, 25, Bradford 24, Brighton 17, Bristol 19, Burnley 21, Cardiff 8, Croydon 10, Derby 24, Dublin 38, Edinburgh, 21, Glasgow 24, Gateshead 26, Halifax 22, Huddersfield 16, Hull 28, Leeds 23, Leicester 16, Liverpool 29, London 22, Manchester 23, Newcastle-on-Tyne 26, Norwich 26, Nottingham 19, Oldham 20, Plymouth 17, Portsmouth 17, Preston 30, Salford 25, Sheffield 22, Sunderland 30, Swansea 15, West Ham 18, Wolverhampton 29. The highest annual death-rates per 1,000 living, as measured by last week's mortality, were:—From measles, 1.4 in Bradford, 3.3 in Salford, and 3.9 in Preston; from scarlet-fever, 1.3 in Burnley and Preston; and from whooping cough 1.0 in Birmingham and in Liverpool, 1.3 in Preston and in Leeds, and 1.7 in Salford. In none of the large towns did the death-rate from "fever" or from diarrhoea reach 1.0 per 1,000.

The 98 deaths from diphtheria included 37 in London, 26 in Sheffield, 4 in Leeds, 4 in Liverpool, 3 in Glasgow, 3 in Brighton, and 3 in Leicester. One death from small-pox was registered in Hull, but not one in any of the other towns.

The Mortality of Foreign Cities.

THE following are the latest official returns, and represent the last weekly death-rate per 1,000 of several of the populations:—Calcutta 39, Bombay 101, Madras —, Paris 21, Brussels 16, Amsterdam 33, Rotterdam 28, The Hague 20, Copenhagen 21, Stockholm 18, Christiania 18, St. Petersburg 29, Moscow 30, Berlin 19, Hamburg, 17, Dresden —, Breslau 25, Munich 22, Vienna 20, Prague 24, Buda-Pesth —, Trieste 32, Rome 22, New York (including Brooklyn) 18, Philadelphia 21.

PASS LISTS.

Royal College of Physicians, Edinburgh; Royal College of Surgeons, Edinburgh; and Faculty of Physicians and Surgeons of Glasgow.

THE quarterly examinations for the Triple Qualification in Edinburgh were concluded on January 27th with the following results:—

First Examination, Four Years' Course.—Of nine candidates the following six passed the examination:—

Ed. Henry Smyth, David C. Williams, Honorine Forbes, James Levack, Ernest A. J. Ersser, Beadon Clarke, and one passed in the division of Chemistry.

First Examination, Five Years' Course.—Of fifteen candidates the following seven candidates passed the examination:—

Alexander B. H. Pearce, Adam W. Hall, William Fleming, William S. Batten, Lionel P. M. Alexis, Samuel J. Graham, Wilthew T. Nicholson, and two passed in Elementary Biology and one in Chemistry.

Second Examination, Four Years' Course.—Of fourteen candidates the following nine passed the examination:—

Alexander C. Campbell, William D. Lawton, H. E. Blackwood, D. C. Williams, Y. J. A. Campbell (with distinction), Thomas J. Evans, James M. Campbell, William E. MacManus, and Thomas Dow.

Second Examination, Five Years' Course.—Of twenty-three candidates the following fourteen passed the examination:—

John J. Adrien, Thomas W. McCubbin, Mary Lytle-Lytle, William J. Bates, John Boyd, Robert P. H. Blackstock, Donald Grant, Thomas Gibbons, Stanley L. G. D. MacLaine, Roger L. Williams, Samuel J. Mathewson, James MacLean, Henry Doig (with distinction), and John W. Cross, and five passed in Anatomy.

Third Examination, Five Years' Course.—Of thirty-two candidates the following twenty-one passed the examination:—

J. S. Colquhoun, J. Cotter (with distinction), D. McIntyre, A. J. Hewitt, J. D. J. Bruce, J. Flanagan, A. Buchanan, W. H. Ferguson, J. Crawford, W. Deery, E. G. Campbell, C. H. Farquharson, W. Turner, O. F. McCarthy, H. O. Pomme di Mirimonde, P. Carroll, A. H. Wilson, J. Newton, J. Stewart, C. H. Nash, and Sarah H. Smith, and two passed in Anatomy and three in Materia Medica.

Final Examination.—Of ninety-three candidates the following forty-six passed the examination, and were admitted L.R.C.P.E., L.R.C.S.E., and L.F.P. and S.G.:—

Winifred Nell, E. Burr, J. W. Dow, W. Astin, T. Duff, J. McElroy, G. F. Beachler, F. Jeeves, Isabella A. Watson, M. A. Alabone, A. J. Hewitt, W. Cunliffe, Hilma M. McFarlane, T. Logan, S. W. Morton, A. J. Morkill, B. Girdwood, A. E. Whitehead, T. Holmes, F. A. Georgeson, M. A. G. F. Stoney, F. P. Maitland, Matilda Coutinho, K. Eapen, C. K. Pillai, J. T. K. Thomson, C. A. Vogwell, J. B. Thorburn, G. H. F. Graves, W. B. Heagerty, M. Sullivan, J. Jeaffreson, J. A. MacLardy, W. H. A. Raffel, J. G. Gray, C. C. Beling, A. Bryans, T. Harrison, J. E. Boon, C. F. Brears, G. H. I. Hammerton, C. Bharadwaja, T. F. H. Blake, W. E. Cuthbertson, R. W. Perry, and H. O. Pomme di Mirimonde; and seven passed in the division of Medicine and Therapeutics, three in the division of Surgery and Surgical Anatomy, eleven in the division of Midwifery, and ten in the division of Medical Jurisprudence.

Notices to Correspondents, Short Letters, &c.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a distinctive signature or initials, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

LOCAL REPORTS AND NEWS.—Correspondents desirous of drawing attention to these are requested kindly to mark the newspapers when sending them to the Editor.

READING CASES.—Cloth board cases, gilt lettered, containing twenty-six strings for holding the numbers of THE MEDICAL PRESS AND CIRCULAR, may now be had at either office of this journal, price 2s. 6d. These cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

ORIGINAL ARTICLES OR LETTERS intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

REPRINTS.—Authors of papers requiring reprints in pamphlet form after they have appeared in these columns can have them, at half the usual cost, on application to the printers before the type is broken up.

LADY APOTHECARIES.

LADIES can take out the license of the Irish Apothecaries' Hall on conforming with the regulations, which are almost identical with the other licensing bodies. Regulations to be obtained on application to Registrar. The Assistant's Degree is also open to ladies producing two years' service in compounding.

IRATA.—We fear you have no means of punishing a treacherous nurse except that of not employing her. Any communications on the subject made to fellow-practitioners had better be verbal, as otherwise you would run the risk of an action for libel.

N. T. S.—You will find what you require in the "Aids to Gynaecology" (Baillière, Tindall, and Cox), but we would strongly advise you to consult the larger text-books in preparing for examination.

G. S. A. (London).—It only takes about a quarter of an hour to stain for the gonococcus, but no power under a twelfth is likely to prove satisfactory. You must bear in mind, too, that while the presence of the organism is conclusive evidence of the specific nature of the affection, its absence does not prove the contrary. Bacteriological investigation and clinical observation must go hand in hand in deciding these difficult cases.

HYSTERICAL INSANITY.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—In the report of the conclusion of my address to the Gynaecological Society that appeared in your issue of January 31st, in quoting from Dr. Clouston on "Hysterical Insanity," the percentage should read 2 per cent., not 50 per cent.

I am, Sir, yours truly,

H. MACNAUGHTON-JONES.

Dr. A. I.—A very good formula for a vesicant plaster, the use whereof is not attended by pain, is: Menthol chloral acid, 1 part; spermaceti, 4 parts; cacao butter, 2 parts. Mix and spread on a piece of linen.

MR. JOHN EWENS, of Bristol, calls our attention to a printer's error in his paper on "A comparatively Rare Injury to the Distal Phalanx of the Finger," on page 85 (Jan. 24). The word "alternated" in the second line of the last paragraph should read "attenuated."

"NOW AND THEN."

A CORRESPONDENT writes concerning a parallel drawn under the above title in this journal between our service at the Crime and in the present campaign. He points out that there were just as many volunteer surgeons drawn from civilian sources. He further quotes from a *runch* of the Crimean period a verse that has a somewhat striking general resemblance to recent lyrics:—

"Listen, soldier, to the tale of the tender Nightingale
Tis a charm that soon will ease your wounds so cruel,
Singing medicine for your pain in a sympathising strain,
With a jug, jug, jug of lemonade or gruel."

MR. E. DEAN MARRIOTT (Nottingham).—Letter arrived as we were at press. Is unavoidably held over.

Meetings of the Societies and Lectures.

WEDNESDAY, FEBRUARY 7TH.

OBSTETRICAL SOCIETY OF LONDON.—8 p.m. Specimens will be shown by Dr. A. Routh, Dr. Griffith, and others. Annual meeting. The President (Mr. A. Doran): Annual address.

SOCIETY OF ARTS.—8 p.m. Mr. E. Wilson: Housing of the Poor. **ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN** (Leicester Square).—4.30 p.m. Dr. Eddowes: Burns, Scalds, and Scars. (Post-graduate Course.)

THURSDAY, FEBRUARY 8TH.

NEUROLOGICAL SOCIETY OF LONDON (11, Chandos Street, W.).—8.30 p.m. Annual General Meeting for Election of Officers. Dr. A. Waller: On the Excitability of Nervous Matter, with special reference to the Retina (Presidential Address).

FRIDAY, FEBRUARY 9TH.

CLINICAL SOCIETY OF LONDON (20, Harrow Square, W.).—8.30 p.m. Papers: Dr. Rolleston: A Case of Fatal Hæmo-pneumothorax of unexplained origin. Mr. R. Jones and Mr. Tubby: Further Experience of Cases of Spinal Rectification. Dr. J. J. Perkins and Mr. C. S. Wallace: A Case of Perforated Duodenal Ulcer, Operation, Recovery.

ROYAL INSTITUTION OF GREAT BRITAIN.—9 p.m. Prof. J. R. Green: Symbiosis and Symbiotic Fermentation.

Appointments.

AUBREY, THOMAS, M.R.C.S. L.R.C.P., Assistant House Surgeon to the Bristol General Hospital.
FLOYD, E. W., M.B., Ch.B. Vict., Resident Medical Officer to the Guest Hospital, Dudley.
HAWTHORNE, C. O., M.D. Glasg., M.R.C.P. Lond., Examiner in Materia Medica and Therapeutics in the University of Edinburgh.
JONES, P. T., L.R.C.P. Lond., M.R.C.S., Medical Officer for the Coleford Sanitary District of the Frome Union.
MORLEY, G. F., L.R.C.P. Lond., M.B.C.S., Medical Officer for the Portsmouth Sanitary District of the Portsmouth Island Union.
MULLEN, W. L., M.D., Ch.B. Melb., Acting Medical Superintendent of the Metropolitan Lunatic Asylum, Victoria, Australia.
PALMER, C. S., L.R.C.P., M.R.C.S., Medical Officer for the First Sanitary District and the Workhouse of the Reigate Union.
RIDSDALE, A. E., L.R.C.P. Lond., M.R.C.S., Medical Officer for the First Sanitary District of the Newhaven Union.
ROBSON, F. W. H., M.B., C.M. Edin., Medical Officer for the Burrough Sanitary District of the Ormskirk Union.
STEDMAN, S. B., L.S.A., Medical Officer for the Swinhope Sanitary District of the Caistor Union.
WELD, J. C., L.K.Q.C.P. Irel., Officer of Health for the borough of Carisbrook, Victoria, Australia.
WIGGINS, H., L.R.C.P. Lond., M.R.C.S., Medical Officer for the Second (B) Worthing Sanitary District of the East Preston Union.

Vacancies.

Bath General or Royal Mineral Water Hospital, Bath.—Resident Medical Officer, unmarried. Salary £100 per annum, with board and apartments.
Borough of Southport.—Medical Officer of Health for the Borough. Salary £500 per annum. Apply to the Town Clerk, Town Hall, Southport.
Brixton Dispensary, Brixton, S.W.—Resident Medical Officer for two years unmarried. Salary £150, with furnished apartments, attendance coals, and gas.
City of Liverpool.—Assistant to the Medical Officer of Health. Salary £350 per annum, subject to certain conditions. Applications to the Town Clerk, Town Clerk's Office, Liverpool.
General Infirmary at Gloucester and the Gloucestershire Eye Institution.—House Surgeon. Salary £100 per annum, with board, residence, and washing.
Hants County Asylum, Fareham.—Third Assistant Medical Officer, unmarried. Salary commencing at £125 per annum, with furnished apartments, board, washing, and attendance.
Royal Infirmary, Sheffield.—House Surgeon for three years. Salary £120 per annum, with board, lodging, and washing.
Royal Sea Bathing Hospital, Margate.—Resident Surgeon. Salary £100, with board and residence. Apply to the Secretary, Royal Sea Bathing Hospital Offices, 30, Charing Cross, London.
Ventnor Royal Hospital for Consumption and Diseases of the Chest.—Assistant Resident Medical Officer. Salary £100, per annum, with board and residence. (See advt.)

Births.

WILLIAMS-FREEMAN.—On January 30th at Wavhill, Andover, the wife of John P. Williams-Freeman, M.D., of a daughter.
WINGFIELD. On February 3rd, at Winchester, the wife of Hugh E. Wingfield M.D., of a daughter.

Marriages.

GABE-ISON.—On February 1st at St. Helen's Church, Ashby-de-la-Zouch, John Kees Gabe, M.D., M.R.C.S., of 16, Mecklenberg Square, London, to Grace Winifred, daughter of Edward Ison, Esq., of Ashby-de-la-Zouch.
MCGEAGH RYDER.—On January 31st, at St. Mary's, Crumpsall, Manchester, William McGeagh, M.D., of Liverpool, to Eliza Jane, only daughter of the late W. B. Rydger, J.P., of Gransden Hall, Hunts.
MUDIE SOMERSET.—On January 27th, at All Saints, Margaret Street, London, W., Arthur Mudie L.R.C.P. Edin., of York Lodge, West Norwood, to Marianne, daughter of the late Francis Somerset.

Deaths.

ADAMS. On February 3rd, at his residence, 7, Loudoun Road, St. John's Wood, N.W., Wm. Adams, F.R.C.S. Eng., on his 86th birthday.
BRODHURST. On January 30th, at his residence, 21, Portland Place, London, Bernard E. Brodhurst, F.R.C.S. Eng., late surgeon and lecturer on Orthopaedic Surgery at St. George's Hospital, London, aged 75 years.
SEWELL.—On January 28th, at Lintoch House, Canterbury, Charles Brodie Sewell, M.D. Lond., aged 183 years.
SUTCLIFF.—On January 29th, at Torrington, N. Devon, Edward Sutcliffe, M.D., aged 161 years.

Original Communications.

THE RISKS OF UNOPERATED UTERINE FIBROMYOMATA.

By E. STANMORE BISHOP, F.R.C.S.Eng.,
Hon. Surgeon Ancoats Hospital, Manchester.

THAT all concerned, patient and surgeon alike, should have shrunk from the risks involved in removal of a myomatous uterus in the days when such a procedure had a mortality of 70 to 80 per cent., as it had in 1878, was but natural; especially when experience also showed that in many cases, if the sufferer could struggle on until the menopause, she could escape with her life, indeed, though maimed and impoverished. That the menopause was always delayed in these cases, sometimes to a great extent, was only part of the burden she had to bear, and it is characteristic of women that they do bear such daily, monotonous, wearying burdens with marvellous patience and angelic fortitude. Their duty to their husbands, and above all, to their children, appeared absolutely to forbid their resort to what was then such a desperate way of escape. Through weeks, months and years of discomfort, pain, and the numberless, undefinable, but none the less real miseries due to want of sufficient blood to carry on the various functions of life, they bravely struggled, upheld always by the bright hope insisted upon, and properly so, under those circumstances, by their medical attendant, of a happy issue when once the "change of life" was over. The thought that they would have passed by that time the "summer of life" and all its pleasures, was thrust out of sight, and their troubles accepted by some in a religious spirit as the "cross" they had to bear, by others as part of the common lot of life, in all cases as inevitable; a thing that could only be relieved, a thing, however, which was essentially temporary, and from which time would bring entire release.

Under such circumstances, too, it was certain that medical men in their relations with such patients would lay stress upon the probabilities of such a result, and would depreciate the dangers of the actual position; that text-books and lecturers would reflect the prevailing view of the situation; that unpleasant incidents would be treated as very exceptional, and as in no way altering the main aspect of things. Even if here and there someone realised the risks which any patient suffering from fibromyoma ran, the proportion of these to the 70 per cent. of operation appeared far too little to justify the latter.

But these views require revision when the mortality sinks from 70 to 80 per cent. to 2 to 7 per cent. as it is to-day. Most surgical opinions are bound to depend very greatly upon comparisons, and in direct proportion to the increased safety of operative interference, the dangers and discomfort of any condition

remediable by surgery rise in importance. The discomforts of fibromyoma are known to every medical practitioner; it is wise also to consider more closely than heretofore the actual dangers of unoperated cases.

Such dangers may be divided into two classes. First, those directly due to the presence of the growth itself; secondly, those which render late operation so dangerous when at last it is undertaken—dangers, I mean, not directly due to the operation itself, but imported into it unnecessarily by changes in the tumour itself or in the parts around by delay in resorting to this, the only sure remedy. The latter have their part also in the first category—they themselves sometimes produce a fatal result before any operation is done, but the point I wish to enforce is they do more than anything else to increase the immediate risks in any such operation, and that all of them are avoidable, and utterly unnecessary, if surgical aid is obtained sufficiently early.

The inherent dangers are five: Death from hæmorrhage, death from sepsis, death from pressure upon important organs as intestine, producing intestinal strangulation, or ureter, producing hydronephrosis, pyonephrosis or anuria. Death during pregnancy or following parturition, or abortion. Death from cardiac degeneration owing to persistent loss of blood.

In 1887 More Madden (a) wrote "I cannot call to mind ever seeing any case in which death resulted directly from this disease," and Wallace, of Liverpool said "I have never known a case succumb to hæmorrhage. It can always be checked." These statements represent the ideas currently held at that time. That they were incorrect, and based upon a defective or too restricted knowledge is evident if search is made either among museum specimens, or records of cases. In the College of Surgeons, (England) Museum, No. 4723, is a specimen removed from a young woman after death from profuse hæmorrhage. The specimen is sent by Dr. Goodhart.

In St. Bartholomew's Hospital Museum is a preparation, No. 2985, Ser. 43, from a case in which death resulted from hæmorrhage following spontaneous opening of an uterine sinus in a case of fibromyoma. The case is described in the *Edinburgh Medical Journal*, 1863. Vol. 9 p. 627, by Dr. Matthews Duncan.

Dr. Favell (b) in 1889 reported a case in which the patient died from sudden and profuse hæmorrhage.

Bignon (c) in 1892, reported a case in which death was caused by internal hæmorrhage following the rupture of a sinus at the back of a large tumour, after a blow upon the abdomen.

Deaths due to sepsis are more frequent, and are usually secondary to necrosis of the tumour itself.

In St. Bartholomew's Hospital Museum No. 2951 A is a specimen in which death was due to the after

(a) *British Medical Journal*, 1887. Vol. 1, p. 52.

(b) *British Medical Journal*, 1889. Vol. 2, p. 1,159.

(c) *Nouv. Arch. d'Obstet. et de Gynec.*, 1892. Supplement, p. 159.

effects of a sloughing fibroid. In this case the matting of intestines above in order to shut out the infective material from the general peritoneal cavity is well shown; whilst the tendency to pocketing of pus in cavities below is equally illustrated.

Gervis (a) in 1883 reported a case in which a large submucous fibroid sloughed suddenly and completely, without any obvious cause or premonitory symptoms. There was also double pyosalpinx and one tube had ruptured, causing fatal peritonitis.

Lediard (b) in 1883 reported a case of death from sepsis, miliary abscesses being found in both kidneys, and infarcts in the spleen, and again in 1894, (c) another of death from peritonitis, with miliary abscesses in the kidneys and septic changes in other organs.

Edis (d) in 1888 reported a fatal case with acute general peritonitis; both Fallopian tubes thickened and distended, whilst both ovaries contained small abscesses.

Cotter (e) in 1889 reported a case with diffuse suppurative peritonitis, and death in consequence.

Schatelig (f) reported a case where death was due to chronic general peritonitis.

The St. Thomas Hospital Reports of 1895, give particulars of a case admitted with a large sloughing fibroid. Patient died without operation from septicæmia.

Dr. Lombe Atthill (g) in 1881 reported a case in which pus was found in the tissues of an uterus, containing two large fibroids, removed after death, and in which case a fatal result followed from septic embolic pneumonia.

Deaths from pressure on important organs, as the ureter are mentioned by Kelly (h), Henry Morris (i), and Gouget (k). In the Transactions of the Obstetrical Society of London a case is reported by Cullingworth (l) in which pressure upon the intestine had been so great that the cæcal wall gave way from over-distension, and fæces escaped into the abdominal cavity, producing a fatal result. In the College of Surgeons' Museum (London) is a preparation, No. 4642, from a case in which death was caused by strangulation of a coil of intestine by a band formed between two calcified fibromyomatous masses.

Although fibroid disease appears to favour sterility in women, it by no means ensures it, and should pregnancy occur the risk to life is greatly increased. Abortion under these circumstances is very likely to occur, and should it do so, the prognosis becomes very grave. Should the tumour be interstitial, the due contraction of the uterus afterwards is greatly obstructed, whilst if submucous, and the attachment of the placenta have any relation to it, hæmorrhage from this site becomes almost uncontrollable. Lefour collected thirty-nine cases of abortion with fourteen deaths, a mortality of 36 per cent.

The College of Surgeons' Museum contains a specimen, No. 4639, taken from a woman who died twelve hours after an abortion at four months. Peritonitis with high temperature preceded the abortion. The tumour in this case was not even interstitial, but subperitoneal, and attached by a pedicle four inches long, to the left side of the fundus uteri.

Parturition in cases of fibroid tumour is always a matter of difficulty, often of grave danger. Of 147 cases collected by Susserott (m) the forceps were

required in 20, with a loss of 8 mothers and 13 children. In 21 cases, the placenta required manual removal, and of these 13 women died. Collectively, the maternal mortality was 53 per cent., the infantile 66 per cent. Tarnier, out of 6 cases delivered by forceps, lost 4 mothers and 4 children. Five women with fibroids died before delivery. Hogan reports a case of pregnancy in a fibroid uterus. Death. Some cases are not capable of delivery by the natural route. Sanger collected 43 cases where Cæsarian section became necessary—the maternal mortality was 83·7 per cent. Pozzi, 28 cases, maternal mortality 86 per cent. Johnston estimates that during pregnancy or labour one-third of the mothers and more than half of the children die; and recommends celibacy where the tumour cannot be removed.

Excessive and persistent losses of blood have their own effect upon the central organ of the circulation. At the Berlin Congress of Gynæcologists in 1899, Gottschalk insisted on the degeneration of the myocardium frequently associated with fibromyomata. Freund said that diseases of the heart and blood vessels are very commonly associated with them, and that they are on that account far less innocent than is generally supposed. Kelly says that "hyaline degeneration of the heart, muscle, and arterial sclerosis are sometimes seen in old cases," Hoffmeier speaks of the frequency of cardiac disease in cases of abdominal tumour, especially in fibromyomata. He collected 18 cases in which sudden death occurred from heart failure, 3 of fatty disease, and 15 of brown atrophy.

But especial importance attaches, I conceive, to changes in the tumour or its environment due to delay, and which immensely increase the danger of operative interference when, at last, it becomes imperative.

In the first place, however, without any of the changes to be described, excessive previous losses of blood may so deplete the patient as to render her unable to bear the necessary traumatism involved in even a slight operation. This is illustrated by a specimen, No. 4632 in the Hunterian Museum, taken from a patient of Sir Spencer Wells. The woman was æt. 32. She had had profuse menorrhagia for several years, threatening her life. The patient died of shock four hours after a comparatively easy enucleation.

The changes referred to are of five kinds.

First and foremost is the danger of inflammatory adhesions. These are often complicated with if not entirely due to inflammations occurring in the Fallopian tubes and ovaries. Meredith in an analysis of Tait's cases, estimated that 54 per cent. were complicated with tubal disease, and 46 per cent. with chronic ovaritis. Twombly estimated that 50 per cent. of interstitial fibroids were complicated with affected tubes sooner or later in their course. These complicate unnecessarily operations in three ways. First, they greatly lengthen the time required for the safe enucleation of the tumour or uterus. Secondly, by their contraction, they alter the normal relation of parts, rendering possible, even probable, the laceration or wounding of the gut or ureter, and anyone who has had, as a sequel to a tedious hysterectomy, to suture either the one or the other, knows how immensely the chances of such a patient have been decreased, both by the time during which the abdomen must remain open, and by the additional traumatism, to say nothing of the prospect in after years, should the patient survive, of possible stricture of one or the other tube. Thirdly, there is the risk of leakage of some infective material during the process of removal. A very good idea of the formidable problem presented to the surgeon in such cases, may be obtained by a study of a preparation in St

Bartholomew's Hospital Museum, numbered 2951A, contributed by Dr. Griffith.

Secondly, and often associated with the above, is the chance of necrosis or sloughing of the fibroid itself. In the Transactions of the Obstetrical Society, Vol. 32, p. 171, is an account by Mr. Bland Sutton of a case in which death resulted from peritonitis a few days after an operation for removal of a sloughing myoma. At the autopsy, shreds of gangrenous tissue were found projecting from the abdominal ostia of the Fallopian tubes. The specimen, No. 4602A, is to be found in the College of Surgeons' Museum.

Thirdly, there is the possibility of pressure upon the ureters, with the resulting changes in the kidneys thus produced. I have already referred to these.

Fourthly, in many of these cases, and apparently directly due to the persistent losses of blood, cardiac disease occurs. Authorities have already been quoted for this statement. It is needless to point out how seriously such cardiac changes affect the chances of the patient during and after operation.

Fifthly, a broad ligament fibroid may grow in such a direction as to undermine, and spread out the meso-cæcum or meso-sigmoid. During its development, the changes in position of the overlying gut are so gradual, that no symptoms may be apparent. Removal of the tumour, however, produces at once a sudden alteration, and occlusion or gangrene of the intestine may result. Cases in which this has occurred with fatal results are recorded by various authors.

I have refrained from multiplying instances of these various dangers, but enough are given to prove their reality.

A ghastly account of an operation too long delayed is given by Platonoff. In this case, after opening the abdomen the adhesions were found to be so dense, that all hope of removing the tumour was abandoned. It was, however, now found impossible once more to close the abdominal opening. On two separate occasions, an attempt was made to remove portions of the growth with the cautery, but this had to be given up on account of profuse hæmorrhage. Gangrene set up in the exposed portion of the myoma, which spread upwards. Death ensued. Can anything more horrible be conceived?

But short of anything like this, the operations described by the elder Keith, or by Schröder demonstrate the excessive difficulties encountered by them, and which could only be surmounted by extreme patience, skill, and dexterity. Such cases are still found, and successful results are with them but a small percentage even yet.

It is constantly affirmed that these tumours grow so slowly that many years must elapse before danger arises. This might be true if the danger were confined solely to pressure effects from actual size. Not entirely, however, since fibrocystic degeneration may very rapidly alter the mere size of the growth; but, as I have tried to show, this is by no means the only, or, indeed, the chief risk. A few days since I removed an uterus containing three fibroids the size of apples, besides numerous smaller nodules. In two of these necrotic changes had gone so far as to produce small cavities, the size of large walnuts, containing pus, whilst the left ovary was a bag of pus, firmly adherent to the broad ligament. The symptoms in this case had only existed, so far as the patient knew, for twelve months.

Hermann and Treves have described a case in which such a necrotic focus formed in a fibroid, and discharged itself into the uterine canal, so that on dilating the os, the finger passed into the cavity. Symptoms of disease had existed here for only eight years. The specimen is preserved in the College of Surgeons' Museum, No. 4609B.

Inflammatory adhesions, pyosalpinx, ovarian abscess, sloughing of the tumour itself, &c., are of far more importance than any mere increase in size, and when they occur, not only do they greatly add to the ill-health of the patient, but they immensely increase the difficulties of the surgeon.

Should a cancerous nodule be detected in the uterus of any woman, all surgeons advise immediate operation—but how often is this followed by disappointment? The growth returns, in the scar, in the broad ligaments, in distant organs. The surgeon's handiwork is useless in most of such cases, and the patient sinks into deeper despair at the non-fulfilment of her hopes. She has pluckily gone through what must always be a terrible ordeal for her to face, and her courage, her patience, are all thrown away. In fibromyomatous disease—I am not speaking of sarcoma, sometimes included as a degeneration of this form of tumour—once the diseased organ is removed, and the immediate dangers of the operation are surmounted, there is no return to fear; the thing is over and done with, the unfortunate sufferer is once more completely restored to health and strength, whilst the surgeon has the intense satisfaction of contemplating good work effectively done. Surely it is worth while to ensure a good result by operating under the best possible conditions, and such conditions are only to be obtained in the earlier stages, before inflammatory changes have complicated the case.

If the considerations above detailed are allowed to have their full weight, we ought to hear less of waiting for the menopause in these cases, and, although the statistics of operative work have already immensely improved, the rate of mortality should become still less with earlier, and therefore less dangerous, interference.

THE DILATATIONS AND DIVERTICULA OF THE ŒSOPHAGUS.

By JOHN KNOTT, M.A., M.D., CH B., and Dip.
Stat. Med. (Univ. Dub.); M.R.C.P.I.; M.R.I.A.; &c.

(Continued from page 136.)

In proceeding to discuss the *acquired* forms of dilatation of the œsophagus, the classification of Rokitansky will be found correspondingly convenient. I may, however, mention that in his very excellent work on "Diseases of the Throat and Nose," the late Sir Morell Mackenzie treats the subjects of "Dilatations of the Gullet" under the divisional headings of "Simple Dilatations" and "Traction Diverticula" (of Zenker and Ziemssen). Of these the "simple dilatations" may be either primary or secondary, the former occurring without any obvious cause, and the latter being the result of the stricture of the œsophageal canal at the lower level." He also informs us that the *primary* dilatations "are cylindrical or fusiform in shape, generally affecting the whole length and circumference of the œsophagus, and usually attaining their maximum girth in the thoracic region about the middle of the gullet." The same authority attributes the occurrence of greatest expansion in this situation to the looseness of its connections, on account of which there is so little external pressure.

The number of recorded cases of the *cylindrical* or *fusiform* variety of dilatation is comparatively very small. It is noteworthy that the symptoms in most of the instances—even when not supposed by the observers to be of congenital origin—had commenced before reaching adult age. Indeed, I entirely agree

with the suggestion made by Mackenzie that "it is probable that in many of these cases the predisposing local weakness had existed before birth." Albers long ago expressed the belief that it always originated in this way.

Without quite committing myself to so absolute an opinion as that of the latter pathologist, I will proceed to observe that in the recorded cases of cylindrical or fusiform dilatation of the œsophagus, the amount of expansion was, nearly always, very great. Also, that in the majority of instances, the condition was accompanied by hypertrophy of the walls of the tube, especially of the muscular layers; while in a few instances the opposite condition of attenuation and atrophy existed. This striking contrast makes me to suspect a difference or origin in the respective groups of cases, and I believe that a sufficient number of instances are now on record to show pretty conclusively that the condition in some of them originated in after life.

A case bearing specially upon this question and of great interest, both in its clinical history and pathological anatomy, was published by Hannay in the *Edinburgh Medical and Surgical Journal* of July, 1833:—

"J. L., æt. 38, had suffered from dysphagia from early boyhood. The commencement dated from the receipt of a violent blow on the chest. Ever since he had suffered from uneasiness in the epigastric region, and difficulty in swallowing, the morsel appearing to be arrested opposite a little point above the lower end of the sternum, and giving rise to the most painful and protracted efforts of deglutition. The symptoms became gradually worse, and had lately amounted to an agonising sense of distension, which remained for several hours after each meal. Immediate relief could be obtained by vomiting. The passage of a probang met with no obstruction. He had of late complained of a constant sense of oppression in the chest, made worse by any violent exertion. His symptoms were always aggravated by any intemperance. . . . He was found dead one night in his chair, after walking home about two hours before from a supper party, where he had indulged rather freely in the good things of the table."

On examination the œsophagus was found enormously dilated, and filled with ingesta.

"The dilatation began immediately on its entrance into the chest. The cervical portion was perfectly natural. It grew gradually wider till it reached the middle of its course in the thorax, there the sac measured, as it lay collapsed on the table and unopened, rather more than three inches across, and when fully distended with fluid, more than six inches in circumference. The thoracic portion alone required about eight gills of water to fill it, and when so filled it looked like the arm of a person fifteen or sixteen years of age. From the middle of the thoracic portion it gradually diminished in capacity till it reached its appropriate aperture in the diaphragm, where it was of its natural dimensions. . . . The parietes of the tube were several times their ordinary thickness, and, comparatively speaking, dense and strong; they had lost almost all trace of muscular texture; the appearance of a section of these reminded me of a piece of sole or thick leather. They had a good deal of blood in them and seemed very vascular. Its internal or mucous coat seemed very vascular, arborescent, and red; it was, as it were, spotted with abrasions of its cuticle, and felt rough and scabrous to the finger. Some parts are smooth, and being less red, appeared almost natural. There was no obstruction, either by tumour external to, or constriction within, the canal."

In his remarks on this case, Hannay expresses his belief that the appearances above described were the result of repeated attacks of inflammation. The

vascularity and swollen condition of the walls of the tube supported this view; so also did the symptoms which had been present during life: the painful sensations, the aggravation by any act of intemperance, &c. "The surface, absorbed and irritable-looking, had all the appearance of recent inflammation." The explanation of the process of enlargement, which he gives in concluding, appears to me to be quite satisfactory. "Repeated attacks of inflammation of the œsophagus had probably destroyed its muscular structure and its contractile power. Swallowing was impaired; the food was detained and accumulated; and the distension of the ingesta had by degrees mechanically dilated the canal." The first attack had probably followed the injury which the organ had sustained at the time of the receipt of the blow.

Rokitansky appears to me to have had the above case in his mind's eye when he says, in speaking of dilatation: "It appears to be sometimes the consequence of a concussion of the œsophagus by a blow or contusion of the chest." These words are, to say the least, very indefinite; and he does not trace the development of the pathological condition any further. Niemeyer questions this explanation; but like Rokitansky himself, does not seem to have considered the sequence of the changes to which the results of the application of such violence may give rise. Another theory of the origin of dilatation, which Niemeyer mentions only to condemn, is that of Oppolzer, who had attributed its origin in some cases to the treatment of gout by imbibition of large draughts of warm water. I entirely agree with Niemeyer in the negative opinion that the draughts of warm water were not the effective agents in the production of this condition. The patients who had been in the habit of using them were of a well-established gouty diathesis. It has been satisfactorily demonstrated that some gouty patients have been subject to repeated attacks of inflammation of the gullet. There can hardly be a question raised in objection to the statement that one of the inevitable consequences of such repeated attacks of inflammation would be a diminution of contractility and elasticity in the walls of the tube; as a consequence of which they must easily yield to pressure of any kind, whether applied by the media of "large quantities of warm water" or of the ordinary ingesta. Accordingly, it is to the gouty condition—with its complications and sequelæ, that I attribute the œsophageal dilatation in such cases; an opinion in which, I am glad to say, I have been supported by the testimony of my late distinguished friend Sir Morell Mackenzie in his criticism of this view—which I had announced in the verdant days of my medical studentship.

A very interesting and remarkable case of dilatation of the œsophagus, attributed to the strain produced by lifting a heavy weight, has been placed on record by my friend Dr. Henry Davy, of Terenure, Dublin:—

"The patient, a gentleman of 38, had given himself a severe strain in lifting a heavy weight, and felt as if something had given way inside. From that period he had suffered from difficulty in swallowing, and nausea and vomiting after taking food. If he attempted to lie on his left side he felt a smothering sensation, and soon threw up quantities of a slimy fluid, which was free from acidity or disagreeable taste. The symptoms gradually became more aggravated. When seen for the first time by Dr. Davy, he suffered from a feeling of 'raking or tearing' in the epigastric region whenever he attempted to swallow. He also suffered from a sensation of heat and burning along the course of the œsophagus, and experienced an obstruction to the passage of food opposite the right margin of the ensiform cartilage.

He vomited considerable quantities of slimy mucus, especially in the morning after sleep. 'The sickness was in a great measure relieved by lying on the right side; his appetite was craving and he suffered much from thirst.' In the epigastrium there was felt a pulsation resembling that of aneurysm. In this situation there was also considerable pain, and tenderness on pressure; and on percussion there was marked dulness. He was also suffering from obstinate constipation, and had a hard, dry cough.

"Under treatment he recovered so well as to be able to resume his situation, and during the next five years the only inconvenience from which he suffered was that he was obliged to take his meals in a semi-recumbent position, with his right arm over the back of a chair, having found by experience that this was the only posture that would allow the passage of food into his stomach; in any other position he felt very uncomfortable, and experienced a smothering sensation that brought on a fit of coughing.

"A sudden aggravation of his symptoms, like that for which he had been treated by Dr. Davy, proved fatal, in about eleven days, from inanition, the stomach retaining no food.

"On post mortem examination, the œsophagus was found 'enormously dilated throughout its entire course, resembling the colon in appearance when distended with air, and measuring at its broadest part (the upper part of its lower third) nine inches, and through the rest of its circumference above and below about eight inches; its muscular coat was very much hypertrophied. The œsophagus was slightly distended with flatus, and contained about a wineglassful of brown fluid like tea, which was prevented from entering the stomach by a twist or volvulus at its cardiac extremity, at its passage through the diaphragm. The circumstance, in my opinion, accounted for the facility which which Mr. R— swallowed when he stretched himself, by undoing, so to speak, this twist. On filling the œsophagus with water, we found it was capable of holding two pints of fluid, and we observed that the mucous membrane was studded at the dilated part with several irregularly-shaped ulcers, varying in size from a pin's head to a two-shilling piece. We also perceived innumerable small white spots (cicatrices), the remains, no doubt, of old ulcers which had healed. The cardiac extremity of the œsophagus readily admitted the index and middle finger, and there was no indication of malignant disease, aneurism, or tumour.'"

It is worthy of note that in neither Hannay's case nor Davy's did the general nutrition of the patient's system seem to suffer so much as might have been anticipated from the severity of the symptoms.

In a case recorded by Purton ("London Medical and Physical Journal," XLVI, 540), the patient sank exhausted from the effects of dysphagia, which had commenced in boyhood. It was first noticed after the receipt of a violent blow on the sternum, and had continued—with progressively increasing severity. There were, however, irregular periods of greater or less remission of the symptoms, and this state of things went on to the period of his death. On examination, the œsophagus was found dilated; the expanded portion forming a sac which reached from two inches below the pharynx to the cardiac orifice. The interior of this sac presented, in a certain (slight) degree, the rugous appearance of the gastric mucous membrane.

Another case, which appears to be somewhat better known than those already given, was published by Mayo. The patient, a female, died at the age of 33, in a state of extreme emaciation. This condition was the result of persistent vomiting of all food; almost everything was rejected a few minutes after swallowing, except when a large draught of fluid was

taken, a certain portion of which was usually retained. Nothing else seemed to her to quite reach the stomach. At the autopsy the œsophagus was found to be enormously dilated—excepting about an inch and a half of its pharyngeal, and an inch of its cardiac, extremity. The greatest expansion was at a distance of four inches from the cardiac orifice, where the tube, when distended, presented a diameter of two-and-a-half inches. The symptoms had commenced during pregnancy, and had lasted ten years before the fatal result.

(To be continued.)

Therapeutic Notes.

By GEORGE FOY, M.D., F.R.C.S.I.

THE EFFECTS OF ANTIPYRIN IN EXCESSIVE COFFEE DRINKERS.

IN a recent communication to the Société Médicale du Louvre, two cases were brought forward of nervous attacks, accompanied by eruptions, following on the use of antipyrin in patients who were addicted to the abuse of coffee (Dr. Pappillon).

The author considers the effects of the excessive use of coffee and of alcohol produce very similar, if not identical, the delirium tremens of coffee drinking being in every respect the same as the delirium tremens of alcohol.

His first case (*La France Médicale*), was that of a young Belgian girl, æt. 19, born of neurasthenic parents, well nourished, withal hysterical and marked on the body with stigmata.

From her youth up she had drunk large quantities of black unsweetened coffee, taking a litre daily. No unpleasant effect was noticed until February 22nd, 1899, when at five in the morning she was seized with migraine, on her return from a dance. She took two doses of antipyrin (calculated to be from two to three grammes) and lay down to sleep. Half-an-hour afterwards, finding sleep did not come to her, she ascribed her wakefulness to having missed her ordinary drink of coffee before lying down. Very soon she felt an intense pruritus of the skin, and soon afterwards an erythematous rash appeared. Bullæ appeared on the face, dorsal surfaces of the wrists, and chest. Coincident with this was profuse lachrymation. She sat up in bed, but on attempting to rise she fell on the carpet. The maid, coming into her room at midday, found her semi-comatose, and did not rouse her.

At two o'clock in the evening Dr. Pappillon found the patient covered with a bullous rash, such as sometimes follows antipyrin. When roused from her stupor the patient appeared violently agitated. Her limbs were trembling rapidly in oscillatory movements, and a slight nystagmus was present, which, however, she was able to control by an effort of the will, the reflexes were exaggerated, epileptiform movements took place, her lips quivered, and she talked incessantly.

She was given a cup of strong, well-sweetened black coffee with some bread and butter, which she ate with relish, and she quickly regained her normal state. The rest of the day was passed as usual: she took no coffee on going to bed; sleeplessness and trembling returned, and on taking half a cup of coffee she immediately became quiet, and towards morning she slept for two hours.

The patient was now put on sweetened coffee, and the quantity gradually lessened; in 12 days it was wholly discontinued, and all the unpleasant symptoms disappeared.

The second case was that of a man, æt. 35, who visited the out-patient department of the Lariboisière

Hospital. He was a great smoker, but in no way nervous. He had called to consult the author for pseudo-anginal pains, which disappeared on his discontinuing the use of tobacco. But to the abuse of tobacco succeeded the abuse of coffee: Coffee was his stimulant; black coffee in the morning, coffee after each meal, without counting one or two cups in the middle of the day and at bedtime; the cup of coffee replaced his pipe. Coffee became necessary for the efficient discharge of his clerical duties, and he increased the number of cups and their frequency. At the beginning of October he suddenly stopped the use of the coffee, with the immediate supervention of migraine. He sent a servant to a chemist for a remedy, who returned with antipyrin powders (about one gramme in each). The patient took four powders within a short time, and very soon afterwards was covered with a violet-coloured and very itchy rash. When seen the rash had in parts become converted into bullæ; the limbs were all trembling; the patient was very greatly excited, and very talkative. A large glass of strong black coffee was at once given, with the effect of calming the patient: and on administering a second all the unpleasant symptoms passed away completely.

The after-treatment consisted in a gradual diminution of the amount of coffee taken daily, until he finally discontinued its use.

From investigations, carried out at the Dispensary of the Eighteenth Arrondissement, the author has found that the infants of mothers who affect excess in the matter of coffee are intolerant of antipyrin.

He concludes that (1) coffee acts as does alcohol on the nervous system, (2) that antipyrin is contra-indicated in those who use coffee to excess.

TREATMENT OF SCARLATINA BY ARSENIC.

The treatment of scarlatina by arsenic, introduced in 1896 by M. Sperensky (*La Médecine Moderne*), has, during a recent epidemic of the disease, been tested by M. Semtchewko. The epidemic was of a serious type, the cases were complicated ones, and some cases of diphtheria occurred. Prior to the use of arsenic some deaths took place, and determining to change his treatment M. Semtchewko gave arsenic a trial. He prescribed it as a curative agent to fifty-two children, and as a prophylactic in ninety-three cases. Under the treatment the fever did not reach such a high temperature as in the other cases, and all the characteristics of the disease were of a distinctly more favourable character.

The mortality of those treated with the drug was 17.5 per cent., and in the same district the mortality of those not so treated reached 39.10 per cent.

In a former epidemic in the same locality, which is not in a proper sanitary condition, the death-rate reached 52 per cent. He considers that the drug simply acts by augmenting the resisting power of the economy to the toxin of the disease. Dr. Bryan, of Leicester, recommended arsenic as a prophylactic to scarlatina in 1882, as did Dr. Walford of Finchley.

MILK FEEDING IN DIABETES.

MM. Wirtenitz and Strasser again recommend milk as the exclusive diet for diabetic patients. A glass of milk should be taken every hour until three litres are consumed. From their record of seven successful cases under this treatment (*La Médecine Moderne*) they find that within forty-eight hours the glycosuria wholly disappears, or, at least, is greatly lessened. The best results are obtained in young subjects—elderly obese patients, and those in whom the disease follows an injury, are not promising cases. The cases treated when put on a mixed amylaceous diet had no return of the glycosuria.

TREATMENT OF LEUCORRHOEA.

Dr. Landau (*Deut. Med. Woch.*) recommends the

use of yeast in the treatment of leucorrhœa, due to the presence of the gonococcus. He employed this treatment in more than 48 cases, in the great majority of these cases the discharge ceased after two applications. Landau used yeast cultivation liquid, and injected this to 20 cubic centimetres into the vagina.

On introducing a medicated tampon, which he kept in place for 24 hours; two patients complained that it gave them a painful burning sensation; none of the other cases found any unpleasant effect.

He considers that the effect is produced (1) by the expulsion of the microbes producing the leucorrhœa by a mechanical action due to the increase of volume of the yeast; (2) by the destruction of the nutritive substance necessary for the pathogenic microbes; (3) by the therapeutic action of the yeast and its products.

SUPPURATION OF THE PANCREAS.

M. Guinard (*Société de Chirurgie*) made a report on the successful treatment by M. J. L. Faure of suppuration of the pancreas. The patient, a man, æt. 22, suffered violent epigastric pains, his pulse was frequent, and he vomited incessantly. A laparotomy revealed the abscess. A fistula marks the position of the incision.

ZINOL.

Zinol (*Corriere di Medicina*) is a mixture of one part of acetate of zinc and four parts of the sulpho-lactate of alumina.

A solution of 1 to 3 grammes in a litre of water is recommended as an injection in gonorrhœa.

COCAIDINA.

Signor Schaefer (*Corriere di Medicina*) reports the discovery of a new alkaloid in the leaf of the coca, to which, from its similarity to cocaine, he has given the name *cocaidina*. Its fusion point is higher than that of cocaine, and it is less soluble in ether and petroleum. It forms crystallisable salts which are soluble in water and alcohol. It has anæsthetic properties, but their duration is not so permanent as those of cocaine.

CAKODYLATE OF SODIUM.

Dr. G. Rénaut warmly recommends the kakodylate of sodium (*Corriere di Medicina*) as the most suitable salt for the administration of arsenic in phthisical cases. Its tonic effects are well marked; it does not produce gastric irritation. The dose is from 12 to 24 centigrammes, but a single dose of 1 gramme has been given without unpleasant effects. In cases of pulmonary trouble, Dr. Rénaut prefers to give the drug by the rectum or by hypodermic injection, the dose by this latter method being from 0.003 to 0.06 grammes in the twenty-four hours; the medicine should be given for eight consecutive days and then left off for a week, then the administration is to be recommenced.

He claims that the effect of the drug are more satisfactory are produced by Fowler's solution, and its rectal injection produces no irritation of the mucous membrane of the bowel.

Arsenicum forms with alcohol radicles compounds. Some in the methyl and some in the ethyl series, which have been examined; of these, one of the best known is arsenic—dimethyl, or cakodyl. Considerable interest attaches to it as the starting point of the inquiries into the organo-metallic bodies. Cakodyl was obtained by Bunsen by the action of granulated zinc on its chloride. It has the formula $2(AsC_2H_5)_3$. Cakodylic acid has the formula, $H(AsC_2H_5)_3O_3$, and the cakodylate of sodium, $Na(AsC_2H_5)_3O_3$. Cakodylic acid crystallises in oblique equilateral prisms, which are soluble in water and in alcohol. It is remarkable that it possesses little or no poisonous action upon the animal system, seven grains of it

having been injected into the blood of the rabbit without producing marked effect. It is a weak acid, and decomposes the carbonates slowly.

DORMIOL.

Huchs (*Corriere di Medicina*) has given the name "dormiol" to a compound of the hydrate of chloral and the hydrate of amyl, which he recommends as a good hypnotic. It is an oily liquid, colourless, smelling of camphor, slightly soluble in water, soluble in alcohol, in ether, and the oil acids. The dose is from fifty centigrammes to one gramme.

ASPIRINA.

This substance is obtained (*Corriere di Medicina*) by the action of anhydrous acetic acid on salicylic acid. It is recommended as a good remedy for rheumatism. It occurs in the form of a white, finely-crystalline powder, slightly soluble in warm water, and in alcohol and ether. The gastric secretion does not decompose the substance, but the pancreatic secretion liberates the salicylic acid. It is given in gramme doses twice or three times a day.

GALLOFORMINA.

Galloformina (*Corriere di Medicina*) is obtained by the action of gallic acid on tetraminescamethylene. It crystallises in fine needle-like masses, slightly soluble in water, ether and alcohol. Taken internally it acts as an antiseptic acid from its property of giving off formaldehyde in the presence of the intestinal juices.

OXAFOR.

Oxafor is the name given to a 50 per cent. solution of oxygen in alcohol (*Corriere di Medicina*). It is strongly recommended as a remedy for dyspnoea. Rumpel introduced the remedy for the laboured dyspnoea caused by cardiac disease, emphysema, bronchitis, and consumption.

It is given in doses of 50 centigrammes to 2 grammes in the 24 hours.

ANTIMELLINA.

Antimellina is the name given by Boersch (*Corriere di Medicina*) to a glucoside obtained from the fruit of the *Syzygium Jambolanum*, which is said to give good results in the treatment of diabetes mellitus.

A NOTE

ON THE USE OF THE

ESSENTIAL OILS FOR INHALATION.

By LENNOX BROWNE, F.R.C.S.Ed., &c.,

Consulting Surgeon to the Central London Hospital for Diseases of the Throat, Ear, and Nose.

ALL that emanates from Dr. Robert Lee on the subject of inhalation is interesting, and in offering a few words thereon I do not for a moment doubt his facts. I venture, however, to think that the question of the true evaporability of the essential oils to which he draws attention in the last issue of the MEDICAL PRESS & CIRCULAR was settled and systematised nearly thirty years ago with the publication in 1872 of the first edition of the "Throat Hospital Pharmacopœia," in the preparation of which I had the honour to take an active share, being assisted, perhaps I should rather say guided, by so able a chemist as Mr. Lloyd Bullock, who is still alive at a venerable age.

The experiments with essential oils were much more detailed and accurate than can appear in a Pharmacopœia. We found that for all practical purposes the majority of the oils—all, indeed, that were of therapeutic value—were best prepared for the purpose of inhalation by suspension in water with a medium of light carbonate of magnesia, for the most part in the proportion of half a grain to each drop of

oil. But it may be mentioned that there was considerable variation in the amount of essential oil that can be comfortably inhaled, for while the prescribed dose of oil of Cubebs was six minims for each inhalation, that of Cajeput was only one. On the other hand, that of Calamus aromaticus (sweet flag), though by no means irritating to the olfactory sense, was found to be almost too powerful a stimulant to the respiratory tract, even in the dose of half a drop in a pint of hot water. All these oils, and many others, were evaporable when mixed with water at a temperature of from 140 to 160 degs. F.

Another point of interest was that the oil of Hops did not prove to be the sedative we expected, and in later editions of the "Pharmacopœia" Lupuline was substituted. This is, however, inferior to the official Conium inhalation. Dr. Robert Lee would appear to advocate a more general employment of these essential oils for inhalation. With all respect, I am of opinion that the almost complete disuse into which they have fallen is more than justified; since the inhalation of steam, however modified its relaxing effects may be by the addition of stimulating ingredients, should be restricted to those patients who from the nature of their illness are confined to the house; nor is the risk of catching cold insured against by the precaution of Morell Mackenzie that "the patient should not go out of doors for half-an-hour after inhaling." For those pursuing their daily vocation oily or spirituous solution of menthol, creasote, guaiacol, iodoform preparations, &c., employed as sprays under air pressure, are now generally preferred.

Clinical Records.

VICTORIA HOSPITAL FOR SICK CHILDREN, CHELSEA.

A Case of Inward Displacement of the Lower Epiphysis of the Humerus. (a)

Under the care of Mr. D'ARCY POWER, M.B.Oxon, F.R.C.S., &c.,
Surgeon to the Hospital.

THIS is a case of inward displacement of the lower epiphysis of the humerus, skiagram whereof I am enabled to hand round. The patient is a girl, æt. 6, who fell upon her left arm in September, 1899. It was impossible to obtain details of the accident, which happened in Cornwall, but the arm had been kept in splints for six weeks. She was admitted to the Victoria Hospital for Sick Children on January 1st, 1900, on account of a deformity of the elbow. The arm was in a state of cubitus varus, that is to say, the long axis was directed inwards at the elbow, but there was neither shortening nor wasting. The movements of flexion, extension, pronation and supination, were unaffected, and the patient only complained of a little pain over the projecting external condyle. I hesitated therefore to perform any operation, thinking that if I did so the last state of the arm might possibly be much worse than the first. The skiagram shows that it would be quite easy to chisel away the projecting angle of the shaft of the humerus. I think, however, that it would be better to do this when the developmental processes at the elbow have been completed. I may point out that the case belongs to a very obscure class of injuries to the elbow, whose exact nature is now only becoming known by the application of the Röntgen rays. The skiagram shows that the separation of the lower epiphysis of the humerus had been subperiosteal, and had resulted in a shifting of the whole epiphysis towards the inner side. The displacement has led to the external condyle of the humerus losing its cartilaginous covering; whilst the cavity of the olecranon has its long axis oblique instead

(a) Case shown at the Harveian Society, February 1st, 1900.

of vertical. The epiphysis appears to be fixed in its new position by an ossification of the periosteum which was probably injured at the time of the accident, and by an increased width of the internal condyle which serves to support the epiphysis in its new position.

CLINICAL SOCIETY OF LONDON.

MEETING HELD FRIDAY, FEBRUARY 9th, 1900.

SIR R. DOUGLAS POWELL, Bt., President, in the Chair.

FATAL HÆMO-PNEUMOTHORAX OF UNEXPLAINED ORIGIN.

DR ROLLESTON related the case of a male, æt. 21, whose past history showed nothing but dyspepsia. After some diarrhoea and abdominal pain, lasting two days, he was suddenly seized with agonising pain in the right hypochondrium, radiating to the umbilicus and right shoulder. On admission 24 hours later to St. George's Hospital he appeared moribund, but subsequently he rallied, and next day had signs of right pneumothorax, with considerable displacement of the heart. Some doubt existed as to whether the collection of gas was above or below the diaphragm. Paracentesis of the right side of the chest brought out blood and some air at considerable pressure. Death occurred from exhaustion and bronchitis eight days after the onset of acute pain. At the autopsy the right pleura contained 60 ozs. of blood. The thoracic wall was opened under water, and no air was found in the right pleura. Except for collapse the lung was healthy. Microscopically there was no evidence of tubercle or pleurisy. There were no signs of hæmophilia, scurvy, cirrhosis of the liver, aneurysm, or traumatism. No cause for the blood or for the gas in the pleura was forthcoming.

Dr. NEWTON PITT reported a case of

RAPIDLY FATAL HÆMOPNEUMOTHORAX, WHICH WAS APPARENTLY DUE TO THE RUPTURE OF AN EMPHYSEMATOUS VESICLE.

The patient was a young man, æt. 18, who had always enjoyed good health. On September 15th he had a sore throat, vomited three times, and had his bowels opened twice, but he was only confined to the house for a day. He went out for a walk at 4 p.m. on Sunday the 19th, but had to return on account of pain in the right chest and shoulder. This increased during the night, and at 4 a.m. he was extremely ill, with intense pain and collapse. At 8 a.m. he was cold, pulseless, and had vomited. When seen in consultation with Dr. Stokes, of Highbury, at 3 p.m., there was evidence of an acute pneumothorax, with dulness over the right base, the heart was pushed over, so that the impulse was 2 ins. to the left of the nipple line. The heart rate was 150; there was no pulse at the wrist. In order to relieve the intense pressure, a Southey's tube was inserted in the sixth space in the axilla, with the intention of allowing the fluid and gas to gradually escape into a large antiseptic dressing, which is the most satisfactory method of dealing with a pneumothorax. It caused surprise to see some ounces of blood escape, after which the tube became blocked with clot. It was reinserted further forwards, when blood and air bubbled out. The pain and distress increased, and were not at all relieved by the operation; it was therefore concluded that the hæmorrhage was continuing. An injection of morphia was given to quiet him, with the intention of again attempting to relieve the tension next day, should the hæmorrhage cease. He died, however, the same night at 8 p.m. At the inspection, the right pleura was found to contain eight pints of fluid blood, with as much clot as filled the hands three times, and also a considerable quantity of air. The lung was tightly compressed, the heart pushed over to the left. A careful examination was made for the source of the air and blood. No perforations or injuries could be found, nor was there any trace of a tuberculous, inflammatory or

necrotic lesion in the lung. The heart, aorta, pleura, and lung were normal, with the exception that there was an emphysematous bulla, about half an inch in size, torn open, situated near the apex of the lung, and attached to this was a ruptured adhesion, the size of a knitting needle, from which the blood may have come, but no aneurysmal pouch or large patent vessel was visible. The lesion is undescribed in medical works. Punctured wounds of the lung and chest might produce this condition, which it may be supposed must also occasionally result from any acute process, which destroyed both the wall of a blood vessel, and also the lung tissue near the pleura, such as a caseous pneumonia, gangrene or abscess; but cases due to these causes do not appear to have been recorded with the exception of a reference by Sausser.

In reply to the President, Dr. PITT mentioned that there were 8 pints of fluid blood and two or three hand-fuls of clots.

Dr. HINGSTON FOX referred to the case of a man, æt. 44, particularly healthy and robust, who developed symptoms of pleural effusion with fever. He was tapped on the tenth day, when 14 ounces of dark blood came away. Three days later, signs of pneumothorax having supervened, the operation was repeated, and 45 ounces of blood came away along with much air. The patient had since made a good recovery. No family or personal history of phthisis. Discussing the etiology, he remarked that the patient had been employed in a very ill-ventilated office with defective drains, and three of the nine employees had broken down within six months, the other two with hæmoptysis.

SIR DYCE DUCKWORTH thought that the sequence of events in these cases was rupture of the lung, with ordinary pneumothorax, followed by hæmorrhage, and behind the whole of the phenomena was tuberculosis.

Dr. S. WEST recalled a curious case of pyo-pneumothorax in which pus was evacuated, and this was followed by hæmoptysis. At the autopsy they found an old tuberculous cavity in which an aneurism had broken, and as the cavity also communicated with the pleura the blood escaped both ways.

Dr. PERCY KIDD asked whether the bacillus capsulatus aerogenes could be excluded, remarking that in neither of the cases was there any trace of tuberculosis.

The PRESIDENT said that the question of the precedence of the pneumothorax and hæmorrhage required to be cleared up. He had once made experiments to see how much fluid could be pumped into the chest, and the most was six or seven pints. He said it was curious that the blood remained liquid in the presence of air.

Dr. ROLLESTON, in reply, said his patient had had diarrhoea and abdominal pain which might be thought indicative of a toxic influence. He did not think that the bacillus capsulatus aerogenes would be likely to die out, so that if it produced air during life it would probably produce much more after death.

Dr. NEWTON PITT, in reply, said the only symptoms that preceded the acute attack were sore throat and diarrhoea, three days before, but he was unable to affirm any connection between them and the attack. He had expected to find tuberculous lesions, but had failed to do so. With reference to the quantity of blood he recalled a case in which seven pints of fluid had been removed from the pleura, and on looking up the records he had found cases in which as much as eleven and twelve pints were said to have been removed.

MEERS, J. J. PERKINS AND C. S. WALLACE ON A CASE OF PERFORATING DUODENAL ULCER—OPERATION—RECOVERY.

Patient, a male, æt. 52, was admitted to St. Thomas's Hospital complaining of epigastric pain of three days' duration, with a violent exacerbation six hours before. There had been no vomiting. The abdomen was tense, rigid, almost motionless, with complete absence of liver dullness in the nipple line. Ten hours after the onset of acute pain the abdomen was opened through the right rectus; the age and sex of the patient, the history and the absence of liver dullness making it probable that a duodenal ulcer had perforated. A perforation was discovered at the

junction of the first and second parts of the duodenum; the edges were clean cut and showed no sign of induration. The intestines showed some points of injection, but there were no very evident signs of peritonitis. The perforation was closed with two rows of sutures, and the abdomen cleaned with evisceration and flushing with sterilised water. The abdominal opening was closed with silkworm gut sutures and by a row of buried sutures. A gauze wick was left in passing down to the seat of ulcer without further drainage. Convalescence was uneventful—the plug was removed on the second day, the bowels were opened by enema on the third day, and milk first given by the mouth on the tenth day. Operation on these cases is favoured by the site of the perforating ulcer, which in twenty-nine out of thirty-seven reported cases was on the anterior wall. The condition of the abdomen when seen early is that of early peritonitis, rigidity, contraction, and loss of movement. Paroxysmal exacerbations of pain due to peristalsis increase the resemblance to colic. The complete absence of the liver dullness internal to the nipple line is to be taken as a guide. In locating the perforation to the duodenum the previous history of the patient is an aid in perhaps half the cases, though perforation in many cases occurs without the slightest previous warning. The site of the pain caused by the perforation at its onset is of great help though occasionally misleading. From statistics it is clear that duodenal can hardly be diagnosed from gastric ulcer. The resulting peritonitis is sometimes diffuse from the first, but often the great omentum shields the mass of the intestines and directs the extravasation to the pelvis. The right lobe of the liver on its upper aspect and the parts round the duodenum are especial sites of the inflammation in these cases, and special care should be taken in cleansing these regions. The whole abdomen, however, should be irrigated, the intestines being turned out and themselves flushed. Drainage is not required, but a gauze wick should be left in the abdominal wound running down to the site of the ulcer. The collapse which is a marked feature of these perforations high up should be met by saline infusion, and operation proceeded with as quickly as possible.

Mr. BATTLE remarked that the diagnosis was difficult and the treatment somewhat delicate. He had seen more than one case in which the perforation was either not found or was treated unsuccessfully, and he referred to a case at St. Thomas's, thought to be duodenal, which turned out to be gastric.

Mr. BARKER challenged the author's statement that the proper treatment of cases of this kind was evisceration and irrigation. He admitted that in years gone by he had followed that practice, but with greater experience he, in common with many other surgeons, had abandoned it. Speaking with considerable experience of perforating ulcers of the stomach, he had come to the conclusion that the less one meddled with the abdomen the better. He remarked that the peritoneum could dispose of a great deal of septic matter, and all that was necessary was to reduce the dose of poison within the limits of its action.

Mr. PRACE GOULD criticised Mr. Barker's assumption that the fluid effused into the peritoneum was septic, and he suggested that this material was very irritating on account of its extreme acidity, and in virtue of its effect on the intestine it might favour secondary infection through the damaged walls. He thought it was best to remove the fluid lest it should become septic.

Dr. POYNTON said that during two years at St. Mary's Hospital he had made necropsies on no less than eight such cases, and he had seen several other cases, diagnosed as such, in the wards. Six of the eight were in males between 28 and 55 years of age. One case showed no symptoms at all during life. All the ulcers except one were extremely chronic, and all but one had made their way through the entire thickness of the intestine and had formed a new floor by adhesions. There was usually a long history of dyspepsia and pain. The ulcers were all situated in the first part of the duodenum, sometimes in front, sometimes behind, and with one exception, were single. He thought the chronic nature of these ulcers explained the important features of the disease; the severity and prolonged

duration of the pain. The diagnosis during life was so uncertain that one hesitated to advise morphia injections. Medical treatment required to be persevered in to afford relief. He remarked that great dilatation of the stomach might be present apart from stricture. He remarked that the association of duodenal ulcer with chronic renal disease was distinctly strengthened by his series, in five of them the kidneys being cirrhotic and containing cysts. He did not see how the renal lesion could cause the ulcer and suggested that there was some common underlying cause.

Mr. CHARTERS SYMONDS agreed that evisceration was dangerous and, moreover, unnecessary. Between that practice and Mr. Barker's practice of merely mopping out the fluid there was a middle course, flushing and sponging, which he thought was the best plan. In a case of his own seen six hours after perforation, the man recovered without drainage. He referred to two cases of a duodenal ulcer in which he divided the duodenum for the relief of gastric dilatation. One patient had recovered, but the other had died from hæmorrhage.

Dr. POYNTON, in reply, remarked that the absence of adhesions was remarkable in perforating ulcers of the duodenum as compared with the non-perforating ones.

Mr. T. H. KELLOCK on a case of

STRICTURE OF THE SMALL INTESTINE FOLLOWING STRANGULATED HERNIA.

The patient, a youth, æt. 16, was admitted to the Middlesex Hospital for strangulated left inguinal hernia. Two years previously he had been operated on at the West London Hospital for hydrocele in connection with an imperfectly descended testis on this side. He had had a hernia some time, but he had always been able to reduce it easily; he had not worn a truss. He had strained himself on the morning of admission, the hernia came down and he could not reduce it. On admission he was a good deal collapsed and vomiting; the swelling in the left inguinal region was as large as an orange. At the operation there was no fluid in the sac, which contained a piece of discoloured omentum and about 4½ inches of small intestine, the latter was very dark in colour, but still retained a shiny appearance, and after the stricture had been divided and a little more intestine drawn down the colour improved a little; the intestine was therefore returned to the abdomen, and then the testicle was found lying internal to and behind the hernial sac. It was surrounded by a tunica vaginalis, which contained a good deal of clear fluid, but which did not communicate either with the sac of the hernia or the general peritoneal cavity. The testicle and tunica vaginalis were removed, and the operation completed by closing the inguinal canal and skin by sutures. For three weeks the patient did well, and the wound healed by first intention. Then he began to suffer from slight pain in the abdomen, some vomiting, and occasional slight distension of the abdomen. On one occasion he had a rigor lasting fifteen minutes, when the temperature rose to 102.2, but with this exception the temperature was normal throughout. By the use of medicines and enemata these symptoms were relieved, and the patient was sent to a convalescent home 5½ weeks after the operation. The bowels were then acting regularly, and he was free from pain. During his stay of three weeks at the Home he had occasional pain in abdomen, constipation, vomiting, and some distension of the abdomen, and these symptoms continued more or less till his readmission to the hospital six weeks after his discharge. They were always relieved by aperient medicines, but tended to increase in severity rather than decrease. He was readmitted complaining of great pain in the abdomen, vomiting, and profuse diarrhoea. For a few days he improved under treatment, but then the symptoms returned, so the abdomen was opened in the middle line below the umbilicus. A coil of small intestine was found in the right iliac fossa, which was considerably constricted; the gut above it was hypertrophied and dilated, that below of about normal size, a piece of omentum containing rather large vessels was attached to the front of the coil. This piece of omentum was ligatured and divided, and a lateral

anastomosis made by Halsted's method uniting the intestine above and below the strictured portion. The abdominal wound was then completely closed. For two or three days the patient made fair progress, but then the abdomen became distended and tender, showing evident signs of general peritonitis; vomiting recommenced and the general condition became very bad. The wound was reopened and a drainage tube inserted leading down to the seat of operation. Death occurred about fifteen hours subsequently. At the post-mortem examination general peritonitis was found, the anastomosis was found to be firm and watertight, with a good opening between the portions of blood united. There was gangrene and perforation of the coil of small intestine which had been put out of action by the anastomosis and the mesentery attached to it was hard and puckered. In this portion a stricture was found extending about half an inch in the long axis of the bowel and almost completely obstructing the lumen. Attention was called to the rarity of stricture of the small intestine to a degree calling for operative treatment, as a result of strangulated hernia. The association of inguinal hernia and imperfectly descended testicle is common, but in this case the hernia was not of the congenital variety as the tunica vaginalis was separate from the sac of the hernia. The bowel was returned to the abdomen at the first operation rather than resected, as it was thought it would recover, more especially in a patient of this age. At the second operation the chief interest was in the piece of omentum which was adherent to the bowel; it was noticed at the time that this contained large vessels, but the importance of this fact was not recognised till later. What had apparently occurred was that at the time of the strangulation this mesentery had been severely constricted, and after the return of the bowel it had become adherent to the omentum, and, nourished in this way and not by means of its mesentery, the division of this piece of omentum had cut off the blood supply of the coil of intestine, which had therefore become gangrenous and perforated, setting up a general and fatal peritonitis. It was disappointing that such an unlooked-for occurrence should prove fatal in a case which otherwise promised so favourably.

Mr. BATTLE said that during the last two years he had had four cases of intestinal stricture either secondary to inflammatory changes or of a fibrous character. One was a case of chronic obstruction of the small intestine due to pressure of caseous glands, the patient recovering after lateral anastomosis. The second patient had been operated upon for appendicular disease two years before and came with acute intestinal obstruction. He found considerable cicatricial contraction about the ileum, and he performed enteroplasty unsuccessfully. Two years ago he performed abdominal section on a man of 60 with intestinal obstruction. He found cicatricial contraction of the small intestine, several coils being adherent and twisted. He undid the twist, and the man recovered, but eighteen months later he came in again with obstruction. This time he performed lateral anastomosis, putting three or four feet of intestine out of circuit.

Mr. CHARTERS SYMONDS commented on the author's remark as to the blood supply of the strangulated loop being derived from the omentum, and asked whether the gangrene was limited to the part above the anastomosis or whether it involved the stricture and the part below.

Mr. KELLOCK, in reply, said that nearly the whole loop of bowel below the anastomosis was of a dark colour with a perforation at its apex. The piece of omentum he had ligatured was stretched over this piece of bowel and certainly appeared to furnish its blood supply, its vessels being distinctly larger than usual.

AFTER much palaver and negotiation, the project of an amalgamating the Medical Defence Union and the Medical Protection Society appears to have been definitely dropped. In a sense this is perhaps to be regretted, but possibly a little competition and rivalry may act as useful stimuli here as in other walks of life.

ROYAL ACADEMY OF MEDICINE IN IRELAND. SECTION OF PATHOLOGY.

MEETING HELD FRIDAY, JANUARY 12TH, 1900.

The President, Professor A. C. O'SULLIVAN, M.D.,
in the Chair.

FRACURED PELVIS.

PROFESSOR E. H. BENNETT showed an united fracture of the pelvis involving the brim or inlet of the true pelvis the lines of fracture being placed in the oblique diameters of the pelvis, and obliquely through the sacrum. He presented this specimen to establish the fact that patients even suffering so grave an injury may recover. He had dealt with such a case in the living also. He showed a specimen of this form of fracture that was fatal. He showed two specimens of the form of injury which results in the displacement of the head of the femur, either incompletely or completely, inwards through the acetabulum into the pelvis. Referring to the double vertical fracture of the pelvis, he exhibited an enlargement of Voilemier's plate of this lesion, and stated that in three cases that had come under his care recovery had been complete.

Mr. H. G. CROLY said he had three cases to relate. The first was that of a man thrown off a dray, and the wheels of it went over the pelvis. He was found collapsed, with the symptoms of laceration of the urinary bladder. After death he found the anterior part of the bladder torn, and the os pubis fractured. The specimen is in the Museum of the College of Surgeons. The second case was that of a gentleman whose horse fell and rolled over him. On catching hold of the crest of the ilium he could rock the ilium backwards and forwards. The patient got phlebitis of the veins of the lower extremity, but ultimately recovered. The last case occurred in a lady who fell on her coccyx. It was fractured, as could be diagnosed by inserting a finger into the rectum. By a push backwards the bone went into its place.

Professor BENNETT replied.

EPIPHYSARY FRACTURE OF LONG BONES.

Dr. KNOTT showed a number of specimens of epiphysary fractures of long bones.

Professor BENNETT observed that in cases of compound separation of the lower epiphysis of the humerus the synovial cavity remained unopened, observed that the periosteum of the humerus was practically inserted into the epiphysary cartilage. The lesion consequently was a dislocation of the lower end of the diaphysis, not of the epiphysis, and this part was displaced out of its periosteum like a finger out of its glove, so that there was interposed between the synovial membrane and this diaphysis the tough periosteum of the bone, and the synovial membrane thereby escaped being opened. In dealing with a case of compound separation of this epiphysis in which the brachial artery had been torn, the question arose whether he should amputate the limb at once in anticipation of profuse suppuration. It was urged, however, that a suppurating wound would do the elbow no harm, and that they might save the limb which proved to be the case.

Dr. KNOTT, in reply, said that having formerly seen the ligaments of the elbow-joint only in adult subjects, he always found the anterior and posterior ligaments attached above their respective fossae. The specimen which he had shown them that evening showed the attachment of the anterior and posterior ligaments of the elbow-joint just at the margin of the articular surfaces so settled the question.

SUDDEN DEATH FROM OCCLUSION OF PULMONARY ARTERY.

The PRESIDENT related the case of a woman, *et. 48*, admitted to Sir P. Dun's Hospital for umbilical hernia, on December 4th, and who died suddenly on December 17th, no operative treatment having been employed. The symptoms preceding death were complete unconsciousness, heavy stertorous breathing, contracted pupils, slight frothing at the lips, which were open; the tongue was quite colourless, the face of a dull, leaden colour

the pulse imperceptible, and the heard sounds barely audible. Death took place in about five minutes. At the post-mortem examination an embolus was found plugging the pulmonary artery at its bifurcation, consisting of a clot 7 ins. long, $\frac{1}{2}$ in. wide at one end and tapering to $\frac{1}{4}$ in. at the other, bent three times upon itself so as to form an S. A tumour was found in the pelvis, which consisted of the uterus, distended by a large myoma growing in the cavity of the uterus, and completely filling it. This pressed upon both external iliac veins, and caused thrombosis, with œdema of both legs. The thrombosis, which caused death, probably came from the left long saphena vein.

Mr. H. G. CROLY thought that if intra-pelvic tumours which were so common, could produce this effect of sending a clot up to the pulmonary artery, it was a remarkable thing that death was not more common from this cause in such cases.

Prof. E. J. McWEENEY inquired as to the condition of the portion of lung supplied by the occluded branch of the pulmonary artery. Was it infarcted with blood or obviously anæmic, or in what condition was it? As far as his reading went he believed the enormous length of the embolus to be unique.

The PRESIDENT, in reply, said that the entire pulmonary artery was blocked, as the clot went into the left branch, and blocked the right by projecting into the main trunk across the opening. He had omitted to mention that there was great œdema of the legs, and the superficial veins was tortuous and varicose. He had seen recently in Thoma's Pathology a picture of a case almost identical with what this must have been when lying in the pulmonary artery. The clot, however, was twisted twice, and lay in the pulmonary artery.

EXHIBITS.

Mr. HENRY GRAY CROLY showed—(a) larynx and trachea of child, showing œdema of glottis with tracheotomy tube *in situ*; (b) unusual foreign body—shawl-pin with large glass bead—removed from the male urethra.

Dr. KNOTT exhibited a series of specimens of a hitherto undescribed fracture of the patella.

The SECRETARY (Prof. McWeeney) — (a) a series of cultures to illustrate the effect of certain variations of the nutrient medium on the growth of the typhoid bacillus; (b) sections to illustrate certain points in the morbid histology of a case of extensive tuberculous disease of the intestines, followed by acute miliary tuberculosis of the liver.

The Section then adjourned.

OBSTETRICAL SOCIETY.

MEETING HELD WEDNESDAY, FEBRUARY 7TH, 1900.

Mr. ALBAN DORAN, F.R.C.S., President, in the Chair.

Dr. AMAND ROUTH showed a specimen of "Homologous Female Twins," united along the anterior and lateral aspects, from the manubrium sterni to the umbilicus. They belonged to the group Emprothozygosis, and to the sub-group Thoracopagus. They weighed 9½ lbs., and had a single umbilical cord and placenta. There was one thoracic cavity, with four lungs, each in its own sac, and two hearts, united by a band at their bases, lying in a single pericardial sac. There was a single abdominal cavity and one peritoneal sac. The livers were united, and below the fused arch were two complete stomachs, uniting by two duodena, and passing thence into a single jejunum, which opened into a large pouch, 3½ inches across. From this, two pieces of small intestines issued, ending in a complete cæcum and appendix vermiformis, and were continued by large intestine to a patent anus on each side. There were two kidneys, ureters, and adrenals, and one spleen, in each foetus, and the pelvic organs were normal.

The twins were of thirty-two-and-a-half weeks of intra-uterine gestation, and were stillborn. Their birth, as described by Dr. Abbott, who had attended the confinement, was a difficult one. A head presented, and was delayed after partially passing the vulva, and an

examination proved that another head was impacted in the pelvis, pressing against the thorax of the first child. With difficulty the arms and shoulders of the first child were delivered, and the fact that the twins were united was then discovered.

Finally, they were delivered by traction on the head and arms of this first child, with no more damage to the mother than a torn perineum, which healed well. The mother convalesced normally.

ANNUAL MEETING.

The PRESIDENT then delivered the usual address, and the business of the annual meeting was transacted.

HARVEIAN SOCIETY OF LONDON.

MEETING HELD THURSDAY, FEBRUARY 1ST, 1900.

H. E. JULES, F.R.C.S., President, in the Chair.

Mr. D'ARCY POWER read notes of a case of Inward Displacement of the Lower Epiphysis, which will be found under "Clinical Records."

Mr. JACKSON CLARKE demonstrated the method he employs for supporting the spine in "carries of the cervical and upper dorsal regions," as applied to a patient, æt. 8, in whom the disease was situated about the fifth and sixth dorsal vertebrae. The child had been treated in the out-patient department for over a year and had greatly gained in general health, and the local spinal trouble had much improved. The support used was a form of Chance's splint furnished with an occipital horse-shoe shaped piece to which was added a chin-strap. The principle of antero-posterior support was approved by the late Sir John Erichsen in the form of Taylor's splint, introduced in America in 1870. Mr. Clarke found that Chance's splint, introduced in London in 1850, was simpler and in some ways better. After a long and careful comparison with the various forms of corsets he had no hesitation in deciding in favour of the method of antero-superior support.

In reply to Mr. Drew Mr. CLARKE said that he had based his judgment on an extensive clinical experience.

Dr. HERBERT TILLEY showed two cases of "Chronic Frontal Sinus Empyema" in which the radical operation had been performed. In both cases the disease was bilateral, and relief was sought for nasal obstruction and profuse purulent discharge. He had operated on both sinuses in the female and, as yet, on one side only, in the male. Both patients were practically cured except the young man who still had a discharge from the left, untreated nostril. In neither case was headache a prominent symptom. In both cases the maxillary antra also contained pus. Dr. Herbert Tilley laid great stress on the importance of removing intranasal pathological conditions before proceeding to the external operation. His usual line of treatment was to remove the nasal polypi or unhealthy granulations from the region of the middle meatus and also, in all cases, the anterior half of the middle turbinate bone which was nearly always diseased in chronic cases, and formed an obstruction to free drainage from the frontal sinus. If the antrum contained pus it should be drained by the alveolar method. When the middle meatal and anterior ethmoidal regions were healthy then the external operation might be undertaken with every prospect of success. This consists in making an incision down to the bone along the minor third of the line of the eyebrow terminating just above the internal palpebral ligament. The anterior wall of the sinus was entirely removed if the sinus was only of moderate size, otherwise only a portion of the wall. The diseased mucous membrane is then thoroughly curetted and a large opening made into the nose (an enlargement of the wound free to nasal canal) which should be sufficient to admit the tip of the little finger passed up from the nose. A drainage tube is then inserted in cases where the sinus has not been entirely obliterated. The wound is closed at the end of the operation by one or two stitches, and the resulting scar, as in these cases, is hardly noticeable.

In reply to Mr. Power, Dr. TILLEY said that the

dangers of operative interference in this region were much minimised by careful preliminary study of and acquaintance with the anatomy of the parts involved, as the frontal sinus did not develop till seven years of age, and remained small till after puberty, such treatment as had been described would very rarely be called for in young people.

Dr. WHITFIELD showed a case of

ACNE VULGARIS, COMBINED WITH MARKED SEBORRHOIC ECZEMA.

This patient, a boy, *æt.* 16, was in the grocery trade and worked very late hours in hot rooms, but he stated that his general health had never suffered in any way. For about three years he had suffered from acne of the face; for about a year he had noticed that his head had become very scurfy and that red spots occasionally came out on his chest. During the last month the condition of the head and chest had become much more marked, and red spots had come out on his back and face. On examination one was at once struck by the presence of enormous numbers of comedones on the face, especially on the forehead and cheeks. Most of these were large and prominent, but few only were much inflamed, pustulation being present only in slight degree. The skin of the face was noticeably greasy, a condition which might be partly accounted for by insufficient washing, but was undoubtedly more than a mere accumulation. The whole of the scalp was covered with a very thick greasy scale, which extended downwards in a gyrate manner on to the left side of the forehead. Where the rash reached the forehead it was seen to be of a florid red colour with very defined outline and covered with a yellowish scale. On the chest and back a considerable number of comedones could be seen, without any inflammatory areola around them, and in addition to these was a number of discoid patches, varying in size from that of a small lentil to that of a sixpence. These patches could be traced from single follicular papules and, when they had extended centrifugally, they became bright red hyperæmic spots, without infiltration, but covered with an adherent and rather greasy scale. The condition thus strongly simulated psoriasis at the edge of the hairy margin of the scalp, and on the chest and back. There were, however, no other lesions on the knees and elbows, and the facts that the disease was associated with a general seborrhœic condition of the skin, and that these psoriasis-like spots took origin from small follicular papules would seem to justify the diagnosis of seborrhœic eczema. Some observers are inclined to identify seborrhœic eczema with psoriasis as one and the same disease, and I myself believe them to be distinct, and, while admitting that the differential diagnosis is occasionally very difficult, I see no reason for, therefore, believing them to be identical. I ordered the boy an ointment containing 2 per cent. of salicylic acid and 3 per cent. of sulphur, and if the disease does not yield to this I shall add some oil of cade to the ointment.

TACHYPNŒA IN ASSOCIATION WITH UPWARD DILATATION OF THE STOMACH.

The patient exhibited by Dr. W. EWART, an upholsterer, *æt.* 18, has suffered from infantile bronchitis and from habitual cough, and for four years from shortness of breath on exertion. She had recently been laid up in bed for three weeks with rapid breathing, orthopnœa, oppression across the sternum, and discomfort at the left thoracic base. On admission the suspicion that the case might be one of hysterical tachypnœa was not confirmed by the aspect or history. Scattered wheezes were heard in the chest, and the dyspnoea was genuine. The tachypnœa, which was not complicated with any increase of the pulse rate or of the depth of the respirations suggested the likelihood of upward dilatation of the stomach as a cause. This was also rendered probable by the patient's distension and oppression at the lower sternum and regurgitation of bitter tasting food after meals. On examination the stomach was found to be dilated upwards as far as the level of the fourth costal cartilage rising above the level of the cardiac apex which was in the normal situation. The tympanitic note encroached upon part of the cardiac dulness and replaced the dulness

of the left lobe of the liver. The chest did not present the usual signs of emphysema and subsequently gave amply respiratory movements as the patient recovered under appropriate gastric treatment. The tachypnœa was never extreme (53 per minute). On the day when the tachypnœa and respiratory distress were relieved a further examination showed that the upper boundary of the gastric resonance had returned to the normal level. Additional features of interest in the case were the liability to pseudo-rheumatic pains in the joints, the decayed condition of several of the teeth, and the presence of a tape-worm, which had been allowed to remain without treatment for the last four years.

Mr. SEFTON SEWILL said that a point of interest was raised by Dr. Ewart's paper, inasmuch as Professor Artrövy had some time ago described a bacillus constant in the pus of abscesses of dental origin, especially those of a chronic nature. This was named *B. gangrene pulpæ*, and Dr. Wm. Hunter in a paper before the Odontological Society had ascribed to its presence in the stomach several troublesome affections of that organ. The point was the importance of bringing the mouth into a thoroughly healthy state in all cases of disease of the stomach.

Mr. DOUGLAS DREW showed a case of large fibroadenoma of the breast.

The President and Drs. Herbert Tilley, Alfred Eddowes, A. Whitfield and Messrs. J. Jackson Clarke, Edmund Roughton d'Arcy Power, and Douglas Drew took part in the discussions which followed.

Dr. ALFRED EDDOWES showed (1) a rapidly recovering case of "Alopecia areata." The patient, a boy, *æt.* 16, had been treated by several medical men, but the disease had become nearly general and had been looked upon as almost hopeless. Thyroid extract was administered and lysol solution applied locally with the result that the hair was rapidly returning, of normal colour, and the boy was growing fast and improving in every way. Dr. Eddowes believed that the case was essentially leucoderma of hairy parts. (2) "Coccogenic sycois," which had begun on upper lip, apparently from infection by discharge from the nose, which latter had in turn been caused by discharge from sore eyes. He thought it would be almost useless to cure the sycois without treating the eyes. He had seen three cases of the kind in one afternoon at the Hospital. He applied yellow oxide of mercury ointment to the eyes with a bandage at night, as he considered smearing ointment merely on the eyelids was almost useless, because grease ran off their moist surfaces. (3) "Lupus vulgaris" in a condition like scrofuloderma. (4) A woman suffering from xeroderma of palms and ichthyosis of legs, improving in health and condition of skin under thyroid extract.

Replying Dr. EDDOWES said too many cases of alopecia occurred with leucoderma for the association to be merely accidental. He looked upon alopecia as a condition produced by several causes, and not as a separate, single disease. He had seen leucoderma recover. He now had greater success in treating alopecia than formerly.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.

MEETING HELD THURSDAY, FEBRUARY 1ST, 1900.

The President, Dr. BURGESS, in the Chair.

Dr. BURGESS showed the following cases: (1) A boy with pseudo-hypertrophic paralysis; (2) a woman with argyria; (3) a case of cerebellar ataxia of over a year's duration. There was no optic neuritis, headache, vomiting, and no evidence of syphilis or tuberculosis.

Dr. ARTHUR HALL showed a severe case of tertiary syphilitic ulceration affecting the left orbital and nasal region. The man had acquired syphilis whilst in the army, and had only received six weeks' treatment after the primary infection.

Dr. SINCLAIR WHITE exhibited the following cases: (a) A man, aged 54 years, on whom he had performed supra-pubic prostatectomy for marked enlargement of the middle lobe of the prostate with vesical calculi.

The bladder, which had been in a state of atony for several years, had recovered its tone, and the patient was greatly benefited by the operation. (b) Four cases of resection of the large intestine for cancer. In one case the disease involved the cæcum, and in the other three it was situated in the sigmoid. One of the latter was suffering from acute intestinal obstruction, and resection was preceded by making a temporary artificial anus above the growth. In all four cases a Murphy button was employed, and all made a good recovery. One patient was only twenty-nine years of age. (c) A myomatous uterus removed abdominally with vaginal drainage. The patient made a good recovery, notwithstanding a hernia of the small intestine through the abdominal wound, which was relieved on the third day.

CASES ILLUSTRATING CONSERVATIVE SURGERY OF BONE.

MR. ARTHUR CONNELL showed the following cases:—

Case 1. Lad, æt. 18 had his left hand caught in hay-chopper, the proximal phalanges of the four fingers being divided from dorsal surface, the fingers hanging by flexor tendons and tissues of palmar surface. The phalanges were drilled and brought together with silk-worm gut sutures. Wounds quite healed on eighth day. Patient had good grasp, unimpaired extension, flexion limited. *Case 2.* Patient, æt. 32, compound comminuted fracture of upper fourth of left tibia involving knee-joint. Loose pieces of bone removed, large wedge-shaped part carrying internal tuberosity wired to shaft. Three subsequent operations for small fragments of bone. Perfect movement of joint. Left limb somewhat bowed owing to dropping of internal tuberosity. Patient resumed work one year after accident. *Case 3.* Patient, æt. 23, comminuted fracture of left clavicle, owing to severe fall on shoulder. Attempts at reduction being futile, two silver wire bracelets were passed round fragments, ends of wire bent down on to bone and interlocked, and the periosteum united over these. Wound dressed on eighth day and stitches removed. Result gratifying, position good. Limb unchanged, all movements at shoulder normal.

Prof. MYERS WARD demonstrated the most modern and approved forms of the kymograph, artificial respiration apparatus, volumetric apparatus and other physiological accessories.

PARIS, February 9th, 1900.

ARSENIC IN THE ORGANISM.

At the last meeting of the Academy of Medicine, M. Gauthier referred to what he had said at a previous meeting as to the presence of arsenic in the thyroid gland, and that that substance existed equally in appreciable quantity in the skin, the hair, the nails, &c.; traces also were found in the mammary gland, the milk and the bones. On the other hand, it was never found in the liver, spleen, stomach, intestine, pancreas, nor in the blood. Neither did the excretions contain arsenic, consequently it was only by the skin and its appendages that the product was eliminated. That elimination had for result when it had attained certain proportions as after arsenical treatment, for instance, a considerable growth of the hair. It was through certain aliments, notably cabbage, potatoes, turnips, &c., that arsenic was introduced into the organism. Although very appreciable in some organs, the total quantity of arsenic existing in the normal state was very small; it corresponded to 1-200th million of the weight of the body.

M. Lancereaux confirming the statement of his colleague relative to the growth of the hair under the influence of arsenical preparations, said that in a young

woman submitted for over a year to arsenical treatment which determined symmetric paralysis of both legs, he had seen those limbs covered with long black hair which persisted for eighteen months after the suppression of the treatment.

TETANUS.

M. Petit related two cases of subacute traumatic tetanus which were cured by injections of antitetanic toxin, and by the employment of chloral in large doses. The first was that of a man, æt. 26, a butcher, who cut the thumb of the right hand in handling meat. A week afterwards he was seized with pain and contracture at the extremity of right arm, then trismus, opisthotonos, and contractures of the limbs and the thoracic muscles. The patient was treated each day by an injection of the antitetanic serum, and absorbed from three to five drachms of chloral. At the end of three weeks he had completely recovered. The second case was that of a man who got a wound on the head in removing some planks; it was only three weeks afterwards that the symptoms of tetanus showed themselves. His treatment was similar to the preceding, and at the end of four weeks he left the hospital.

M. Vaquez said that some time ago he had treated a young man who showed slight symptoms of tetanus, trismus and stiffness of the neck. Believing that the affection was benign, he injected but small doses of the serum. But five days afterwards the patient, without any warning was seized with violent convulsive attacks, and in twenty-four hours he was dead. The speaker thought that that fatal termination might have been avoided if a larger quantity of serum had been injected.

RESECTION OF THREE YARDS AND A HALF OF THE INTESTINE.

M. Montprofit said that he was called to a man, who had an inguinal hernia of the size of an adult head, which continued to progress, and could neither be maintained nor reduced.

Having resolved to practice the radical cure of this enormous hernia, he made the first incisions, and when the intestine was brought to view it was found to be in such an entangled and mixed up condition that he decided to remove the whole mass. The two divided ends of the intestine were then brought together and sutured without difficulty. The man made an excellent recovery, and were it not for some diarrhoea each time he eats meat he would have suffered no inconvenience from the operation. The mass of intestines removed weighed three pounds and a half and comprised a part of the ileum, the cæcum, the ascending colon, and half of the transverse colon. The total length was nearly ten feet.

BERLIN, February 10th, 1900.

THE TREATMENT OF NEURASTHENIA.

In the *Munch. Med. Wochens.*, Feb. 3, 1900, Dr. Dornblüth, of Rostock, has a paper on this subject. Before commencing treatment he considers it of prime importance to come to a thorough understanding as to the patient's previous condition and ailments as, frequently, these furnish more or less useful indications. A distinction must be made between the acute and chronic stages, but even in the latter an exacerbation of symptoms occa-

sionally comes on that makes the case for the time much like one in an acute stage. In the acute stage the first requirement is rest, and rest in bed is the best. It is surprising how frequently all the symptoms, those connected with the stomach, the melancholy, giddiness, and oppression, are removed by it alone. Such rest may be required for a period varying from eight days to six weeks. In milder cases it is sometimes difficult to command such rest in bed, but its usefulness is incontestable. When absolute rest in bed cannot be procured, the patient should be enjoined to lie down flat as often, and for as long a time as he or she can each day. For mental rest attention should not be given to business. Loneliness, in the acute stage, very useful to the patient. The tendency to grumbling, which the patient thinks he ought to overcome as much as possible gives way soonest of all to bodily rest in the sick room. A return to occupation should only be allowed after proper rest has been had, and the power of resistance has sufficiently returned.

Diet is of great importance; neurasthenics only require a normal diet. The author understands by this, five meals a day with intervals of two-and-a-half to three hours. He allows coffee and tea, and all not over indigestible articles of food, but unconditionally forbids all alcohol, as it always leaves a lassitude behind it and lowers the recuperative powers of the nervous system. In general, rest after a meal is good, but some patients seem to do better with conversation. A great part of the stomach troubles of neurasthenics are due to insufficient evacuation from the bowels, and disappear when a suitable diet has overcome the difficulty.

Hydro-therapeutics come next, and the author thinks that Preissnitz body wrappings, the half bath and cold wet smacking will suffice. As regard the Preissnitz, the linen cloth should be steeped in water the heat of the patient's room, well wrung out and wrapped round the body. The water used should not be warmer than stated even if the patient expresses a wish to have it so. Over the linen cloth come wrappings of dry flannel, secured with safety pins or bandages. The Preissnitz envelope acts as a calmate, and at the same time a stimulant to the stomach and bowels. The half bath is an ordinary bath, only half filled covering the buttock and lower limbs only. The patient sits up and the front and back are well douched by the attendants, the best temperature is 24 to 25 R. (73 F.), and the bath should last four minutes. The bath is best given soon after a light meal, and the patient should rest a quarter of an hour after it. In drying, rubbing should not be made use of, as only a calmate effect is desired.

The fourth part of the general treatment consists in general Faradisation, a weak current being used preferably through the Faradised hand.

An indispensable part of the treatment lies in psychotherapeutics. Only the truth should be stated, and only what one knows. Any departure from this involves the possibility of contradiction and a shock to confidence.

To these general regulations are now added those applicable to the particular case. A majority of neurasthenics suffer from imperfect constitution of the blood. Krewel's sanguinal pills and arsenic are distinctly useful. According to the case quinine or ext. rhœi may be added to the pills. Arsenic the author generally prescribes in the form of the Asiatic pill, acid

arsen. 0.1, pip. nig. 2.0, pulv. sig. 5.0, and mucilage to 90 pills, of which one is taken three times a day at meal time. After 8 to 10 days 5 to 6 pills may be taken; this may be continued for about 3 weeks, when the 3 pills daily should be reverted to. It is occasionally useful to give large quantities.

In the chronic cases education to labour is of vast importance, especially in those of traumatic neuralsthenia after recovery from the original inquiry, when compensation has been granted and there is a disposition to pass a sort of invalid existence.

ICHTHYOL VASOGEN IN JOINT AFFECTION.

Prof. Edleszen, of Hamburg, has an article on this drug in a recent number of the *Therap. Monats.* (1/1900). The Professor began using ichthyol soon after its first introduction and with good effect. When the vasogen preparation came to hand, he first of all painted the alcohol-ether solution of ichthyol over the joint, and then rubbed in menthol vasogen. He satisfied himself that ichthyol used in this way acted more perfectly and quickly than by simple painting. Since the introduction of the 10 per cent. ichthyol vasogen he has left off the complicated process and has simply used the ichthyol vasogen, and has obtained as good results in a simpler manner. The results were equally favourable in nearly all cases of monarticular rheumatism, and especially in recent cases. In the case of large joints 8 to 10 drops can be rubbed into the skin. In the acute cases the rubbing cannot of course be carried out. In such cases ichthyol should be given internally in the form of pills or capsules, or a return may be made to the older method of painting with the alcohol-ether solution.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, February 9th, 1900.

BACTERIO THERAPY.

DR. IVAN HONL, of Prague, has prepared a history of 100 cases which have been treated by Bukovsky and Professor Janovsky with the protein of bacillus pyocyaneus. The injections of proteins and toxins is no new doctrine, but Professor Janovsky's dressing of indolent ulcers with protein products must be admitted to be a slight deviation from the modern teaching of bacteriologist. His argument is that the bacterial force of an ulcer is varied in character, in it are often found pathogenic, as well as saprophytic micro-organisms. Our object in healing the wound is to free it as much as possible these retarding agents, which so rapidly multiply in spite of antiseptic dressings, such as carbolic, &c. Experiments with the latter and protein dressings are compared to show how ineffectual carbolic is in this respect when compared with protein. Extracts from other micro-organisms, such as staphylococci and streptococci, were proved to act in the same way, the pyocyaneus being more persistent, even refractory, so diphtheria was selected as the most suitable. Any of them are equally potent in the healing of indolent or refractory ulcers.

The protein of the pyocyaneus is obtained in quantity by growing cultures on fluid media, which form a greenish or greenish-yellow pellicle on the surface. From experiments, a suitable age of this culture is found more potent, from which the protein is prepared and

diluted according to Buchner's method. After this fractional sterilisation a dark green, alkaline, cloudy extract is the result. The action of this fluid on healthy animals and man is nil.

The proteine being now ready for use the patient is advised to remain in bed, occasionally putting the extremity affected with the ulcer in lukewarm water. After this the protein lotion is applied twice a day on "hydrophile gaze," which is again covered with a layer of wadding, and finally fastened with a bandage. Of the 100 cases successfully treated only one has been observed to go wrong, i.e., become swollen through a large accumulation of leucocytes. Its salutary action is indisputable. Many false notions are entertained concerning the toxic effect, but it is important to notice that the solution ought to have no bad effects on the organism to obtain sufficient stimulating vital curative force. Another proof of its potency can be demonstrated in the test tube by placing a small portion of this extract in one growing pyocyanus, which instantly checks further progress. The same enzyme action is observed in the lower animals, even proving to be a bactericide for anthrax when injected.

The local application produces no pain, no reddening or subjective symptoms, while the surrounding skin is perfectly healthy. No medicines were given during the treatment, and all the patients expressed themselves as well and comfortable.

Within 24 hours the ulcer will show evident signs of improvement; if a pseudo-membrane be present before the commencement of the enzyme application it will have quite disappeared before the 24 hours. The first dressing and bandaging will be drenched with the discharging secretion which will rapidly disappear in the second or third. The duration of healing is various according to the complications, but in every case it is far shorter than by any other means. Janovsky expresses satisfaction with the results and is sanguine of the future for the protein treatment.

PAUCITY OF MEDICAL STUDENTS.

In recent years the medical profession has not been so much in demand as formerly, and the decrease seems more marked through Austria this year. In Vienna 218 entered for the profession at Prague, 35 Deutsch-speaking and 37 Czechs; Graz, 39; Innsbruck, 24; Lemberg, 13; Cracow, 11; making the small total for Austria of 377.

SUSPICION OF PLAGUE AT CRACOW.

A considerable amount of excitement existed at Cracow last week from the sudden death of the assistant in the Bacteriological Institute under the direction of Prof. Bujwid. Kostanecki, who was considered an able assistant in the infectious laboratory, took suddenly ill, and died on the fourth day with all the symptoms of plague, according to those who attended him, but where the pest came from was a puzzle. Accordingly a post-mortem examination, with microscopic and animal tests, was performed, but the result was a tranquillising report that death was due to "streptococci pneumoniae."

The Operating Theatres.

GUY'S HOSPITAL.

ABSCESS OF THE BRAIN.—MR. ARBUTHNOT LANE operated on a man, *æt.* 33, who had suffered for a week with headache and occasional attacks of vomiting; the temperature was high, and the pulse and respiration

rapid. The headache was most marked on the left side of the head, and there was a good deal of pain and tenderness about the mastoid process on the same side. The membrana tympani was perforated, and there was some foul discharge. He was perfectly intelligent and answered questions correctly and promptly. After a thick, dense mastoid has been removed, the antrum and the petrous bone were found to be much enlarged, and filled with foul-smelling granulation tissue; this was all thoroughly cleared out. The dura mater was stripped both from the upper and posterior aspects of the petrous bone, and there was no evidence of any extra-dural suppuration whatever. On the following day the patient's temperature was normal and he had lost his headache, he was still inclined, however, to be sick. Two days after his headache returned, his temperature rose abruptly and his pulse and respiration again became rapid. The dura mater of the middle fossa which had been freely exposed at the previous operation was now divided, when the brain bulged into the aperture so made; a pair of dressing forceps were passed into the temporo-sphenoidal lobe, when a gush of foul pus took place and about two drachms escaped. The alar cavity was thoroughly washed out and a drainage tube inserted. No optic neuritis was present throughout. Mr. Lane said that the case presented a peculiarity in that, except for the continuance of the vomiting which was trivial after the first operation, there was practically little or no clinical evidence of the presence of a cerebral abscess.

ROYAL FREE HOSPITAL.

NEPHRECTOMY FOR TUBERCULOUS KIDNEY.—MR. BATTLE operated on a woman, *æt.* 20, who had been suffering from pain in the region of the left kidney for a period of from five to six months. The pain had not been that usually associated with the presence of calculus, for it had not been paroxysmal in character. There had been some increased frequency of micturition. The urine had shown a yellowish deposit. There had been no bleeding. During the last month or so the pain had been more severe and almost constant; she had lost flesh, and suffered from night sweats and had been feverish. On examination, the patient was a thin girl with slight hectic flush and somewhat rapid pulse. In the left side of the abdomen occupying the left kidney region, was a large swelling which passed back under the ribs, and moved very little on deep inspiration; it was very tender, and fluctuated in one part. The urine was acid, but contained a deposit of pus. She had the signs of hectic fever but careful examination showed no evidence of tubercle in other parts of the body. The right kidney was enlarged and could be felt, but it was not tender nor in any way changed in its normal outline. The diagnosis was made of tuberculous disease of the left kidney, and as no evidence of tubercle could be found elsewhere it was considered that her hectic was dependent upon the presence of suppuration in the left kidney. The right kidney was regarded as hypertrophied in order to supply the place of its diseased fellow. Everything was apparently favourable for the removal of the tuberculous organ, and it was thought desirable to do the operation of nephrectomy rather than that of nephrotomy with subsequent drainage, because although the former was the more severe operation the patient would get rid of the source

of her trouble, whereas if the latter operation was performed there would be continued drain on the system, which she was ill prepared to sustain. Had nephrotomy been done it would probably have necessitated nephrectomy at a later stage, when she would be still further weakened by constant discharge. Chloroform was administered for the operation, and the kidney removed through a lumbar incision. The capsule of the organ was opened, and the kidney shelled out from it. This was easy in the lower part, but in the upper part it was extremely difficult, for not only had a large abscess developed above and posteriorly, but the adhesions of the kidney to the capsule, and the capsule to the diaphragm were extremely dense, and their greatest resistance was at a point difficult to reach, and most cramping to the operator. After the kidney had been drawn into the wound, the ureter and vessels were ligatured separately, a drainage tube introduced, and the wound closed, separate stitches being used for the muscular layers and skin. The ureter where cut showed some change in its lining membrane, suggestive of the possibility of tubercle, but the condition of the patient after such a severe operation did not permit of further exploration. Section of the kidney showed that besides the large abscess which communicated with the upper and posterior part of the organ there were other centres of disease, most of which had undergone changes into abscess cavities. One of fairly large size occupied the position in front of the kidney, and was evidently the one which gave rise to the sensation of fluctuation when the organ was examined before operation. Mr. Battle said that his opinion when he first saw the patient was unfavourable to the performance of nephrectomy. The patient had a very hectic look, was emaciated, and had a rapid weak pulse, there was a little cough suggesting the probability of lung disease, the right kidney could be felt considerably enlarged and this might have been due to disease on that side also; when, however, examination of the lungs showed nothing more than a little crepitation at the left base when the right kidney did not increase in size, whilst the signs of suppuration about the left kidney increased, he took a more favourable view; he considered that the prognosis in cases of tubercle of the kidney was far better than was generally thought if operation was performed early, and instanced the case of a patient on whom he had performed nephrectomy for this condition some twelve years ago who was still alive and healthy.

GREAT NORTHERN HOSPITAL.

WIRING FRACTURED PATELLA.—Mr. PEYTON BEALE operated on a woman, *et. about 30*, who had fractured her patella three weeks previously. He performed the open operation, and on exposing the patella found that the torn ends of the ligamentum patellæ were firmly adherent to the fractured bone surfaces. The fractured edges of the bone having been cleaned by the removal of the internal ends of the ligament, together with much tough almost cartilaginous tissue, two wires were inserted in the usual manner and the ends tightened up. The aponeuroses on each side were freely divided so as to relieve the slight tension which was present, the cavity of the joint was thoroughly irrigated and the wound closed. Mr. Beale said that in his experience, in about four cases out of every five he found the torn ends of the ligamentum patellæ firmly adherent to the

bone surfaces; unless these were dissected off bony union was of course impossible. It might be asked why should not the operation be done before this adhesion had taken place; if the case could be operated on within one hour of the occurrence of the fracture, it might be possible to ensure bony surfaces being placed in accurate apposition by external manipulation, and then a subcutaneous operation, such as that devised by Mr. Arthur Barker might be performed; but he could not see that there was really any less danger to the patient in this procedure than there was in operating by the open method. In by far the majority of cases of fractured patella the surgeon did not see the patient until some hours after the injury. In most cases the joint was then found partly or wholly distended with blood. If the case was watched carefully it would be found that there was a rise in temperature local and general, which persisted more or less until after the effused blood had clotted, or in some cases until its complete absorption. This might take place in a few days or it might take several weeks. He believed the rise in temperature was due to the absorption of fibrin ferment, probably by the lymphatics, and such a rise in temperature was usual after the rapid effusion of blood into other cavities of the body; he considered that there was grave risk to the patient in operating for fractured patella during this period, as the joint synovial membrane was, under these circumstances, not unable to resist infection should even a few septic organisms be present. He further remarked that it had been stated that bony union never took place even after the most accurate wiring, but against this he could say that in a case under his care some years ago he had occasion to wire a patella which had become fractured two years after a former wiring performed by him. The fracture at the second operation was found to be about $\frac{1}{4}$ of an inch above the site of the previous one, the wire had, of course, been broken, but the line of bone union was complete, and he excised it and had it at present in his possession.

THE SERUM TREATMENT IN SHEFFIELD.—

In a recent article in the "Quarterly Medical Journal for Yorkshire," Dr. Alexander Anderson gives his personal experience of the results of the treatment of diphtheria. In all 258 cases were admitted to the City Hospital during the year 1899, and of these 41 died, equal to a mortality of 15·8 per cent. Owing to the lack of hospital accommodation a comparatively small proportion of the total number of notified cases could find admission, as many as 46 per cent. being admitted on the fifth day or later. This fact amply explains the author's not having obtained an even more pronounced reduction in the mortality, the efficacy of the serum, as is well known, being immensely diminished by any delay in instituting the treatment. Even so, the figures testify eloquently to the value of the method, and Dr. Anderson was able to adduce some very telling details in disproof of the assertion that the reduced mortality was due to the milder type of the disease.

A MAN, who was stated to be Dr. Alexander Forsyth, committed suicide on Friday last at Leyton after fatally shooting a woman with whom he had cohabited.

ADVERTISEMENTS.

FOR A SERIES OF INSERTIONS:—Whole Page, thirteen insertions (weekly, fortnightly, or monthly), at £1 10s. 6d.: twenty-six insertions (weekly or fortnightly) at £3 3s. 0d.: fifty-two insertions (weekly) at £3 each. Half Page, thirteen insertions at 35s.: twenty-six at 32s.: fifty-two insertions at 30s. each. Quarter-page, thirteen insertions at 18s.: twenty-six insertions at 16s.: fifty-two insertions at 15s. each. One-eighth page thirteen insertions at 9s.: twenty-six insertions at 8s.: fifty-two insertions at 7s. 6d.

FOR ONE INSERTION:—Whole Page, £5 0s. 0d.: Half Page £3 10s. 0d.: Quarter Page, £1 5s.: One-eighth, 12s. 6d.

Small announcements of Practices, Assistancies, Vacancies, Books, &c.—Seven lines or under, 4s. per insertion; 6d. per line beyond.

Letters in this Department should be addressed to the Publishers.

The Medical Press and Circular.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, FEBRUARY 14 1900.

POSSIBLE WAR COMPLICATIONS.

THE mobility and accurate marksmanship of the enemy are not the only dangers which the soldier at the front has to fear in South Africa. The difficulty of ensuring adequate sanitation in hastily constructed camps, especially when the energy of the men is fully occupied in warding off attacks, exposes our soldiers to the ravages of disease, foremost among which are typhoid and dysentery, which spread but too rapidly when once they have obtained a footing. Apart from water-borne diseases there are others which may conceivably impair the value of a fighting force, in direct proportion to its size. We have not heard of any outbreaks of variola, and it is to be hoped that the precautions taken to ensure efficient vaccination, at any rate in the regular Army and in the Militia, will prove sufficient to ward off any danger from this source, but how far this holds good of the various volunteer corps it is impossible even to guess. There is, however, always present the danger of the importation of plague by troops arriving from India. Several cases of plague have occurred in or near Delagoa Bay, and the possibility of an outbreak among the soldiers in the field is too awful to contemplate. In view of this contingency it is to be hoped that the Government will take all possible precautions, especially in respect of the means of supplying, if necessary, adequate quantities of the serum. What the value of the serum treatment would be under the peculiarly trying circumstances of a campaign experience alone can decide, but as it is practically the only means, other than rigorous sanitation, which is available for the purpose of nipping a threatened epidemic, its employment would be clearly indicated. The part played by vermin in the dissemination of the plague is now universally recognised, and port

sanitary authorities ought to be specially on their guard against the escape of rats from ships bringing troops or merchandise from parts of the world where the plague exists. In an article on the subject which appeared in a recent number of the *New York Medical Record* we are reminded that the belief that rats were an important factor in spreading the plague was firmly held by the ancient Greeks. Sambon relates that in Asia Minor, at the very door of the plague, they worshiped Appollo "εμυροφ," "that is to say, Apollo the rat, whose arrows spread the plague. and at the same time as the destroyer of rats." This awful divinity was represented on monuments as treading on a rat. In Roman times, when Æsculapius replaced the more ancient god of medicine, we again find the same fact recalled on a coin of Lucius Verus, struck at Pergamum. It represents Æsculapius with a rat at his feet, and a small naked figure standing by with arms outstretched. It is, however, not absolutely proven that the plague is disseminated by rats, although the evidence in support of the theory is remarkably strong—so strong indeed that the destruction of these vermin in infected regions and ships is a course that should, in all instances, be pursued. With regard to the plague in Portuguese South Africa, says our contemporary, there can be no doubt but that it constitutes a grave menace to both the armies in the field. In the first instance it will find an eminently congenial soil amid the filth of the Portuguese towns, and in the second place the transportation of provisions from Lorenzo Marques to the Transvaal will afford favourable facilities for its introduction to that country. In order to prevent so frightful a catastrophe, pressure should be brought to bear upon the Portuguese authorities to induce them to exercise the strictest supervision both over cargoes coming in by sea and over the food stuffs sent inland.

THE ROYAL COMMISSION AND THE LONDON WATER SUPPLY.

THE Final Report of the Royal Commission on the London Water Supply is a document of first importance. Its main conclusions are likely to postpone any real settlement of the question dealt with to an indefinite period, while they bring once again into striking relief the general chaos of administration that characterises the greatest and richest city in the world. Curious as it may seem, there is little doubt that when a small village or a provincial town, such as Manchester, could settle the vital matter of its water supply out of hand, London, with all her unbounded wealth and energies, nevertheless lies helpless at the mercy of competing water corporations and of conflicting local authorities. As most of our readers know, London is divided into an inner administrative county, a far larger area known as "Water London," and a still wider district included within the Metropolitan and City police jurisdiction. Six counties enter into the greater combination, namely: Middlesex, Kent, Hertfordshire, Surrey, Essex, and London itself, as

well as several boroughs and some fifty-six urban and rural district councils. In such a complex tangle of affairs it is hardly a matter of wonder that there should be a variety of opinion as to how an efficient administration may be best secured. The outlying counties have protested with one voice against their water supplies being acquired by purchase by the London County Council. Their chief ground appears to be that only a small proportion of their own inhabitants fall within the jurisdiction of the London Council. The Commissioners regard the present conditions of the water-supply as so intricate that a scheme of physical severance and partition would be impracticable. Their chief recommendation is that the Metropolitan water companies' undertakings should be purchased and placed under the control of a "Water Board." They regarded purchase by the London County Council as inadvisable. This latter view is based upon the assumption that such a step on the part of the Council would necessarily involve a division of the works of supply, which appears to them impracticable. That the results of Lord Llandaff's Commission will prove disappointing to those who anticipated a speedy solution of the problem must be obvious. Some day a comprehensive scheme worthy of Londoners' acceptance will doubtless be brought forward and adopted, but meanwhile the day of fruition has been indefinitely postponed. It has been found possible to give to such cities as Birmingham, Manchester, and Edinburgh good supplies of pure water from more or less distant mountain catchments. What is possible in the provinces can surely not be altogether impossible in London, in spite of the absence of any common municipal vitality in that huge conglomeration of local authorities. The City of London, the nucleus around which greater London has gradually grown, has alone maintained a strenuous tradition of united citizenship, with the natural result that hitherto its finances and organisation have proved unassailable. It is true that the London County Council has introduced some sort of municipal element into the life of greater London, a laudable spirit that may or may not be further advanced by the forthcoming redistribution of districts under Mr. Balfour's Act. Anyway, from an early period of their existence, the London County Council took up the water question, and it is to be hoped their well-known energy and pertinacity will not be staved of by such unsatisfying conclusions as those contained in the Report of the Royal Commission. For years past the annual recurrence of a water famine in the East End of the Metropolis has forced an object lesson upon all citizens as to the good faith and generosity of water companies, who owe their position to concessions granted at the cost of the community. Add to that the fact that Londoners are, for the most part, supplied with water that has been polluted by sewage, and the need for a thorough and radical change in the source of supply must be self-evident. Of the vast amount of disease of unknown origin met with every year in the Metropolis, it seems not unreason-

able to assume that a fair proportion may be ascribed to the drinking of specifically polluted water. In any case, we have no hesitation in asserting that to supply to a community water that has been contaminated by sewage is to run counter, not only to common sense, but also to the established canons of preventive medicine. Yet the Water Commission, if we read between the lines of the Report, asks us to continue the state of things that makes such a polluted supply possible. As we have often pointed out, the water companies have a vast influence, which is constantly excited in their own favour and to the detriment of the people in Parliament as well as in other directions. The chief hope for the future lies in a strong House of Commons that will not allow capitalists to stand in the way of the interests of the community. It is to be hoped that the London County Council, having laid their hand to the plough, will not be deterred by any amount of opposition from their set purpose of securing to greater London a municipal supply of pure water, if need be, from the Welsh hills. Some day, as we have already said, that consummation must be brought about, and the longer it is delayed the greater the damage, direct and indirect, to the pockets and the health of those who are by virtue of position the unwilling drinkers of water that has been subject to dangerous and revolting pollution.

THE ARMY MEDICAL DEPARTMENT AND THE WAR.

If the progress of the war in South Africa so far has proved anything, it has shown, contrary to expectation, that the Army possesses a most efficient medical service. From all sides testimony to this effect has been given. Lord Methuen has even said that he was glad that he had been wounded, inasmuch as the opportunity was thus afforded him of learning how complete and perfect were the arrangements for dealing with his wounded men. All this is, without doubt, very satisfactory; it has silenced the gloomy wailing of the pessimists who prognosticated that the medical service of the Army would show lamentable inefficiency during the course of the war. Moreover, there were not wanting some who affirmed that the sick and wounded troops would be exposed to hardships scarcely less in severity than those which befell our gallant soldiers in the Crimean war. Despite, however, all these prognostications of evil, the reverse has proved to be the case, that is to say, both officers and men from the highest to the lowest in the South African Field Force, have never lost an opportunity of bestowing warm praise and admiration upon the work done by the Medical Department. As showing on the other hand, how closely matters affecting our wounded soldiers are being scrutinised by the public, it may be pointed out that questions were asked in the Houses of Parliament last week respecting some statements as to defects in the military hospitals in Cape Colony and Natal. But the Ministerial reply was well calculated to allay all alarm and anxiety upon this score. The Government were able to produce

telegrams from the Commander-in-Chief in South Africa as well as from Sir R. Buller, in both of which the statements were described as false and ridiculous, and the assurance of Mr. Treves was also given to the effect that there was no possible ground of complaint, and that he could not suggest any improvement upon the arrangements which had been made for the care of the wounded. It is with considerable satisfaction that we are able to make these remarks, for it must not be lost sight of that no thanks are due to the military authorities for the efficiency which the medical department has displayed. Let it be borne in mind in this connection how many times the officers of the Royal Army Medical Corps have been snubbed in their efforts to add to the efficiency of their department. The War Office have repeatedly in the past done their utmost to check enterprise in this direction, but despite the petty jealousies, want of encouragement, and obstructive policy opposed to them, the Medical Department have made the best of their limited opportunities, and it is only true to say that the one bright feature of the war so far has been the care and attention which have been bestowed upon the wounded, and the wonderful perfection which has been shown in the organisation of the medical department generally. To whom, it may be asked, can these results be attributed if not to our *confreres* in the Service? No matter what the results of the war may be, it will have proved one thing, namely, that the Army possesses a Medical department of which the nation has abundant reason to be proud. Indeed, as a matter of fact, both the War Office and the Government owe a debt of gratitude to the officers of the Royal Army Medical Corps for the successful work which they have been able to accomplish, for in truth matters might have been very different had the chronic system of ennobling been taken seriously to heart by the latter. In short, then, we rejoice that our *confreres* in the service have proved themselves equal to the task imposed upon them, and we also trust that after the war a new *regime* will be inaugurated as between the military authorities and the Army Medical Department. It is difficult to see how, for example, Sir Redvers Buller could, after his recent experience of the treatment of the wounded at the battle of Colenso, ever forget his indebtedness to the medical officers of his command. No one probably knows better than Sir Redvers Buller himself the dire consequences which would have ensued had a failure occurred in the arrangements for the succour of the wounded.

Notes on Current Topics.

Dr. Neale and the Profession.

WE publish elsewhere an influentially-signed appeal to the profession embodying a suggestion which cannot but meet with general approval. We refer to the proposal to constitute a fund for the purpose of presenting Dr. Neale, the author of the well-known Digest bearing his name, with a testimonial of some

sort in order to convey to him in tangible form the appreciation of the profession of the public spirit and perseverance which he has displayed since upwards of forty years in compiling the work in question. Members of the profession, and they must be numerous, who are familiar with the "Digest" do not need to be reminded of the immense amount of time and labour which the routine work of posting up the references has entailed. It is not merely a simple and comprehensive guide to the title and tenour of the various articles and contributions which have appeared for more than forty years past in British medical journals, but, viewed as an index, it affords at a glance a working idea of the various methods of treating a given malady, &c. Without such a guide as this, medical literature is a chaotic accumulation of facts, suggestions, and results which virtually defies analysis. The "Digest" is as useful to the busy practitioner as it is indispensable to the author in search of references, and it is to be hoped that arrangements will be made to continue its publication when the time comes for its venerable author to relinquish the task. We understand that something of the kind is contemplated, but before accepting the undertaking it is only becoming that those who have availed themselves of Dr. Neale's labour of love—for it has been such, no question of profit having ever been considered—should seize this opportunity of conveying to Dr. Neale an assurance of their appreciation, coupled with an object which will remain as evidence of grateful recognition of his life's work.

Measles a "Trivial Complaint."

THE fallacy that measles is a malady of little significance still lingers in the popular mind, in spite of the growing intelligence of the community upon such matters. A striking illustration of the deep-rooted nature of that conviction will be found in the current issue of the *North American Review*. In the course of an historical article, Professor Bryce says that measles, when it occurs in civilised countries is, a "harmless childish malady," but when imported among savage nations becomes a deadly plague. The passages occurs as an incidental simile that would not be surprising from the pen of a busy lay journalist who has not time to probe the medical beliefs of the multitude. It is, otherwise, however, with a man of the marvellously wide culture and universal knowledge that characterises Professor Bryce, whom we cannot believe to be unacquainted with the chief features of the Registrar-General's returns for the United Kingdom. As a matter of fact, if we take the seven principal zymotic diseases we find that for the two yearly periods ending 1890—1895 measles comes second highest on the list, which in each case is headed by diarrhoea. Has the learned professor never heard the question mooted as to whether measles should not be made a notifiable disease? Some years ago the point was ably discussed in an article under the heading "Murder by Measles," which appeared in the *Nineteenth Century*, a journal that presumably falls within the scope of professional reading. Apparently it is only when grown-up

savages are killed off in thousands that the deadly nature of measles is recognised; civilised babies do not weigh so much in the intellectual balance.

An Interrupted Pilgrimage.

BETWEEN three and four hundred pilgrims left Marseilles last week on their road to Rome, and all went well until they reached the Italian frontier where they were met by a staff of doctors who had instructions to vaccinate them all, and, failing compliance, the military authorities had orders to refuse admission. It seems that a number of cases of grave variola have made their appearance from time to time in northern Italy, which have been traced to travellers from Marseilles, hence this somewhat drastic measure which resulted in a large number of the pilgrims refusing to submit to the "indignity," and retracing their steps. The example is one which might advantageously be followed nearer home for Government would be perfectly justified in refusing admission to travellers who, failing evidence of recent successful vaccination, refused to submit thereto.

Whisky Drinking.

IN an address recently delivered before a provincial medical society, Dr. Goodhart called attention to the extent to which whisky, as a beverage, had supplanted beer during the last half a century or so, and he did not hesitate to render the medical profession as a body responsible in part for a change which he views as pernicious. Most practitioners of experience will concur in the general truth of Dr. Goodhart's remarks on the subject, though they may be reluctant to accept the responsibility which he would place on their shoulders. The advantage of drinking what may be called "natural" beverages is that excess is immediately followed by more or less acute gastric and physical discomfort which tend to remind the delinquent that he is exceeding the mark. Distilled alcohol, on the other hand, is more insidious in its effects, and produces pathological changes which seldom follow the habitual ingestion of the milder drinks even in comparative excess. During the last two or three decades a great and welcome change has come over the scene in regard to the attitude of medical men towards alcoholic indulgence of any kind, and in view of the position of trust which medical men hold towards the public it behoves them to think twice before giving advice which may be construed into approval or recognition of the necessity for the routine use of alcoholic beverages.

Damages Against a Locum Tenens

AN action which was on the list for trial at the Burnley County Court last week, but which fell through in the absence of the plaintiff, throws a side light on the risks which practitioners run when they hand over their practices to the tender mercies of inattentive substitutes. The claim was for salary due to the plaintiff, Dr. J. F. Wilson, by Dr. F. E. Crossley, whose practice he had had charge of, and who made a counter claim for £50. On the counter claim being tried it was stated that Dr. Wilson

had grossly neglected his duties as locum tenens, and in a specific instance it was stated that he had omitted to visit an elderly patient whom he had been directed to see daily, and it was mentioned that Dr. Wilson had ultimately given a certificate of death, not having seen the patient during life. In reply to a remark by the judge it was stated that the facts concerning the certificate would probably be brought before the General Medical Council. The judge commented roundly on Dr. Wilson's conduct, and gave a verdict against him for £35. The case shows the extreme desirability of ascertaining the trustworthiness of the substitute one proposes to leave in charge, but unfortunately this is often a matter of great difficulty.

Stamp Collectors and Tuberculosis.

A SURGEON in the French army has just discovered that stamp collectors may be the means of disseminating tuberculosis by means of the stamps. He had in his employ a man suffering from advanced pulmonary tuberculosis, in whose sputa the tubercle bacilli swarmed. This man was a great stamp collector, and occupied his spare time in fixing the stamps in albums or on sheets of gummed paper for sale, moistening the stamps for the purpose with his tongue. As soon as it was discovered that the man was using his saliva to moisten the stamps, he was admonished not to continue the practice, and meanwhile 300 of them were taken and placed in sterilised water. Some of this water was used for the purpose of inoculation experiments. Eight guinea pigs were thus inoculated, and each of them died with characteristic tuberculous lesions. The risks which these experiments indicate of tuberculosis being disseminated by stamps should induce care among those handling the latter, and children especially should be warned against placing any stamps near their mouths in order to moisten them. But the tubercle bacilli are not the only pathogenic organisms which could be disseminated. Mention in this connection may be made of the diphtheria bacillus, also that of pneumonia, syphilis and others. Perhaps, however, to make quite certain of newly-bought foreign stamps being free from pathogenic infection it would be advisable to disinfect them in a 5 per cent. solution of carbolic acid, before adding them to collections.

Celery and Typhoid.

A FEW years ago a large number of cases of typhoid fever were traced to the popular water-cress, and there was a great decline in the use of this vegetable in consequence. A somewhat similar report has now been promulgated in regard to celery. Such risks, of course, must always obtain more or less, in the case of all vegetables which are taken from artificially fertilised gardens and eaten in an uncooked state. Inadvertently typhoid infected material might be used to stimulate the growth of celery, and it is not difficult to comprehend how an epidemic of the disease might thus be caused. The possibility, at all events, of such a contingency is

worth noting, especially when seeking to ascertain the cause of an outbreak of the disease which may seem to be inexplicable.

Hydrophobia in Athens.

It is interesting to peruse the statistics of the Pasteur Institute in Athens, where from August, 1894, to the end of 1897 no fewer than 997 persons underwent the anti-rabic treatment. Among the whole number so treated there were only two deaths or a percentage of 0.25. In five persons, however, the disease developed within fifteen days after the last inoculation. Among those not treated at the Institute there were forty persons who died of hydrophobia in twenty-seven of these the incubation period varied from twenty to one hundred and twenty days; in two, from five to six months, in one, from six to seven months, and in one beyond a year. These figures undeniably show a preponderance of results in favour of Pasteur's method. Of course it might be argued that many of the cases treated by this method would probably never develop hydrophobia in any case, but we do not regard such a contention as a reason for failure to submit to the only method of the prevention of the disease which science has been able to elaborate.

Medical Men and Tobacco.

At a recent meeting, at Manchester, of the British Anti-Tobacco League, regret was expressed at the difficulty experienced in getting the medical profession to take up the question. The fact is that although medical men fully recognise the evil effects of excessive indulgence in the weed, they are not sufficiently convinced of the mischief attending its moderate use to take sides; moreover, a very large proportion of medical men smoke themselves, so that they could not very well support a movement which has for object the abolition of the practice. If one may judge from what one sees at medical dinners the proportion of non-smokers among medical practitioners must be very small indeed, and many, among those who abstain from the fragrant weed, do so, not in virtue of any moral principle, but simply because nature has made them unduly sensitive, and intolerant of its effects.

Chloroform Administration.

It is encouraging to find that the principle of regulating the administration of chloroform is gradually making its way. Another important point is to "go easy" at first, in opposition to the vicious plan of giving initial massive doses as advocated and practised in Scotland. Practitioners should lay to heart the remark with which Dr. James Edmunds, the anæsthetist, concludes a letter on the subject addressed to a contemporary. He says: "Now that I have got used to the improved Krohne inhaler, and realise the true significance of the deaths, I should think it a crime to go back to the towel or Skinner's mask." This is an opinion which we have frequently felt called upon to express when recording additions to the interminable list of fatalities under chloro-

form, the vast majority of which appear, as far as one can judge, to be due to simple mal-administration.

More Malarial Observations from Koch.

A SECOND report on his expedition to the Far East has been published by Professor Koch. Although no facts of startling novelty are contained therein, it nevertheless presents various points of interest. In Dutch India his Java headquarters were in Batavia and Ambarawa. In the former place malaria has diminished during the last fifteen years, more than 50 per cent., probably on account of the free distribution of vast quantities of quinine to the inhabitants. The spare time at that place was devoted to testing the communicability of the disease to orang-outangs by injected blood taken from patients suffering with tertian and tropical ague. None of the animals took the infection, but it must not be supposed that other lower animals cannot harbour the specific parasites in their blood. Meanwhile it seems probable that man is the only bearer of the parasites, a likelihood that cannot fail to have a direct bearing upon prevention. The other district, Ambarawa, is swampy, but, contrary to expectation, very few cases were found among adults. Koch concludes that in order to find out whether a district is malarial or not, the children should be first examined. In a hill district, Tosari, which was said to be free of mosquitoes and of malaria, the children were found to be exempt from the disease. In that fortunate spot there is no cultivation of rice, a fact that is in accordance with Professor Koch's observation that the growing of rice and the presence of mosquitoes go hand in hand. The agency of these insects forms one of the most fascinating chapters of modern medical science, and these latest researches appear to confirm the Berlin Professor's dictum to the effect that where there are no mosquitoes there is no malaria.

Poisoning by Coal Gas.

CONSIDERING the extreme toxicity of coal gas when inhaled it is a matter for surprise that fatalities are not more frequent than they are as the result of leakage. This comparative immunity is probably due to its powerful and characteristic odour, but in spite of this protection two ladies recently succumbed to its effects at Wednesbury. The risk is vastly greater when an inodorous illuminant—such as water gas—is used on a large scale, and in the United States, where it has come largely into use, the frequency of fatal accidents have rendered necessary certain stringent precautions. This is a class of risk which the spread of electricity as an illuminant tends to reduce year by year, but so long as gas is used we shall always have to bemoan a long list of victims, due to its explosive and toxic properties.

THE Professorship of Medicine, or the Practice of Physic in the University of Edinburgh, vacant through the death of Sir Thomas Grainger Stewart, is worth about £1,050 a year. It is in the gift of the Curators of Patronage.

Frozen Meat.

CHEAP food is essential to the rapid growth of a nation. Expansion however, may sometimes be paid for somewhat dearly by reason of unsuspected dangers that lurk in imported food stuffs. From this point of view a few words of caution may not be amiss upon the subject of frozen meat, which has of recent years been brought into the United Kingdom in such vast quantities as simply to revolutionise the conditions of our meat supply. There can be little doubt that cold storage lessens the flavour and nutritive value that is found in fresh meat, but the lessening is probably not sufficiently serious to detract from the value of frozen meat. A more important point is that beef, mutton, poultry, fish, and other animal food that has been frozen, as a rule is thereby rendered less digestible. Another point is that such food, when exposed and thawed is liable to rapid decomposition, and there can be no doubt whatever that a great many cases of ptomaine mischief are due to that fact. Now-a-days the use of frozen meat is universal. Butchers in wealthy neighbourhoods, no matter what their labels, supply imported mutton almost exclusively, and to a less extent imported beef. It is almost impossible to distinguish good Australian mutton, when properly cooked, from that of prime British sheep, while the cost of the colonial product is less by about one-third. In the face of the enormous recent growth of the frozen meat trade it is well to impress upon the mind of the average citizen the desirability of having all meat prepared for table as soon as possible after its arrival from the butcher. Further, that he should have a well ventilated and dust-proof larder.

Syphilis and Dentistry.

It seems to be generally believed that syphilis can be conveyed during the act of shaving in barbers' shops, and the mere possibility of such a terrible contingency occurring strongly emphasises the necessity of enforcing absolute cleanliness in regard to the use of all appliances in these establishments. However, a practitioner has just pointed out that syphilis can be easily transmitted by means of dental instruments, and he refers to several cases, notes of which he publishes in the *Journal of the American Medical Association*, in which syphilitic infection was thus conveyed. But the danger in such cases seems to lie not so much in the infected instruments as in the want of acquaintance among dentists of the lesions common to the disease. For example, any dentist, we presume, called upon to attend a patient's teeth who is suffering from syphilitic manifestations in the mouth, would at once take the greatest precautions in the cleansing of his instruments. Perhaps, indeed, there are some dentists who only use one set of instruments for patients who are known to be syphilitic. Wherever this is done, of course, the best safeguard is provided. But if a dentist is not familiar with the oral appearances of syphilis, how is he to know when special precautions are necessary? It is no doubt quite possible to thoroughly cleanse dental instruments

after use upon a syphilitic patient, and render them sterile and safe for use subsequently upon healthy patients, but what is wanted is the knowledge when such processes of sterilisation are most urgently needed. That there is some justification for drawing attention to this subject is undeniably proved by the cases recorded in the journal above mentioned.

War as a Social Disturbing Element.

IN all probability among the many social disturbances which the war has caused, that which relates to the spending of money will be most severely felt. The public have practically been drained of their spare funds in the interests of the soldiers and sailors on active service. Consequently it is not surprising to hear that hospital charities are already beginning to feel the pinch caused by depleted exchequers. In truth there is every reason for believing that great difficulties are in store for those institutions which depend for their support "on voluntary contributions." The philanthropy of the public is not unlimited; nor are philanthropic persons always mindful of the inexpediency—perhaps injustice—of expending all their charity upon one object, which at the time may happen to be the most popular. Undoubtedly the most pressing problem—excluding the war—during the rest of the year will be how to make financial provision for our hospitals, and the outlook is decidedly gloomy.

Leicester and Vaccination.

THE newly-appointed vaccination officer at Leicester has just furnished his first return and it certainly contains some remarkable figures. We learn, for example, that during 1898 there were 6,164 births in the town, and only 87 successful vaccinations. Again, during the first half of 1899 the births were 3,200, and the successful vaccinations 35, that is to say, that in the course of 18 months the births were 9,364, and the vaccinations only 122. Still more remarkable, however, are the following figures:—During 1898, 1,075 exemption certificates were granted, while during 1899 the number was no more than 113. Possibly, therefore, in the future, Leicester, despite its Board of Guardians, may prove to be a well vaccinated community.

DR. HOWARD KELLY, says the *N.Y. Medical Record*, was bitten on the finger by a rattlesnake recently while lecturing at the Johns Hopkins University. He sucked the wound for a few minutes, and then resumed his lecture, apparently not in the least disconcerted by the accident. The subject of the lecture is not given, and one is reduced to conjecture to explain the presence of this uncongenial reptile in the lecture theatre.

THE Hungarian Government is stated to have promulgated a decree placing ritual circumcision under medical supervision with the object of ensuring that it shall always be performed with due regard to antiseptic precautions.

Welsh County Sanitation.

WALES is generally accredited with holding the most backward sanitary position among the countries of the United Kingdom. Some light was thrown upon the causes of that unenviable sloth in a recent discussion that took place in the Monmouthshire County Council anent the recommendation of the Sanitary Committee that a Medical Officer of Health be appointed for the whole county at a salary of £500, with £100 for travelling expenses. The main objection raised against the proposition was that such an official would not have it in his power to do more than make recommendations which the local authorities would not carry into effect. It was further contended that only one Welsh county, Glamorgan, had a County Medical Officer, a fact that seemed highly satisfactory to the opponents of the proposed appointment. On the other side it was pointed out that certain "plague spots" in Monmouthshire were under the care of a Medical Officer engaged in private practice, and that the work done under such circumstances was perfunctory and "not always unbiassed." Alderman Reiffan maintained it was fully time the Council ceased playing with the sanitation of the county. He followed up that home thrust by ridiculing the idea that a County Medical Officer would be powerless, for his recommendation could be enforced through the Local Government Board. In his opinion they were shrinking not from the additional rate of one-sixth of a penny that would be required, but from the recommendations that the officer must make to them if appointed. The determination not to appoint a County Medical Officer was carried by thirty-three votes to twelve, and Monmouthshire has thus formally maintained her right to remain a laggard in the sanitary race.

The Registrar-Generalship for Ireland.

THIS important position has not yet been filled since the death of Dr. Grimshaw, probably in consequence of the serious illness of the Chief Secretary. As the emoluments of the office amount to a large sum, and, as the position is one of honor and influence, there is much competition for it. When it became vacant the choice of the profession fell at once on Dr. J. W. Moore, President of the Royal College of Physicians, who is known, not only as an able and experienced statistician, but as a skilled sanitarian and a cultured writer. He is, however, too busy with practice to allow him to accept of the appointment. Dr. Atthill, representative of the Dublin College of Physicians in the General Medical Council, whose name appeared in an erroneous list in a daily contemporary, also disclaims the honor. As far as we have been informed, the prominent competitors are:—(1) Mr. Robert E. Matheson, (2) Dr. Ninian Falkiner, (3) Dr. Martley, and (4) Dr. Langford Symes. Mr. Matheson is secretary of the department and assistant-registrar, and, if nothing save long and efficient service in the office were to decide the selection, would certainly obtain the desired position. But there is a strong feeling, especially in the medical profession, that no one

can be competent to compile and reason from the statistics of mortality and disease but an expert in medical affairs, and, preferably, one who is familiar with the detail working of the registration system in Ireland. Dr. Grimshaw, during his period of office, has proved the superiority of the medical claim to all others, and we trust that the Government will not ignore the fact.

Dr. Falkiner is a fellow of the College of Physicians, and recently acted as Secretary of the State Medicine Section of the Royal Academy of Medicine. He is also a diplomate in State Medicine of the University of Dublin, and has had many years' experience of the registration system as registrar to one of the North City Dispensaries.

Dr. Martley is also a Fellow of the College of Physicians, and one of its State Medicine diplomates, and he has shown his capacity for compilation and interpretation of statistics by communications on the etiology of cancer.

Dr. Langford Symes is also a Fellow of the College of Physicians, and was for some years registrar of one of the largest districts in Ireland, when he published an exhaustive report of the statistics of Public Health, and an epitome of "The Laws of Public Health." He is additional examiner in Medical Jurisprudence and Hygiene for the College, and investigated "The Mortality of Children in Ireland," bringing the causes of "Infantile Mortality" before the Royal Academy. Many other candidates are spoken of, but, as we have no official knowledge of their candidature, we are not in position to name them.

The Proposed Midwives' Registration Bill.

THE declining interest in this question has been suddenly revived by the announcement that the promoters of the Bill to make provision for it have been so lucky as to secure an exceptionally good place on the ballot, and have fixed the second reading for the 28th inst. It is probable that the Bill will then be pushed over by the Mines Regulation Bill, which has the place before it on the same day, but we strongly advise the opponents of the Bills not to be lulled into inaction by this fact, as it is quite possible that the last-named measure will be disposed of at an early hour.

Royal Visit to Netley.

PRINCESS CHRISTIAN and her daughter, Princess Victoria of Schleswig-Holstein, paid a private visit to the sick and wounded from the war at Netley Hospital last week, and left a bouquet with certain of the more interesting among the wounded as a gift from Her Majesty. They saw in all some three hundred patients, only one-fourth of whom are confined to their beds. The Queen is expected to pay another visit to the hospital during the present week.

THE office of Serjeant-Surgeon and Assistant Serjeant-Surgeon, at one time held by the late Sir James Paget and the late Sir Prescott Hewitt, have not been filled, and it is surmised that it is the intention of Her Majesty to allow them to lapse.

The offices are ancient and comport an annual retaining fee of £280, originally intended to secure the services of the holder to the king on the field of battle.

IN reply to a question by Sir Walter Foster, Mr. Wyndham stated that 368 officers of the Army Medical Corps were employed in South Africa, 377 at foreign stations, and 111 at home. There were 133 civilian surgeons employed in South Africa, and 28 more were under orders to go. There were 112 retired pay officers employed at home.

A PRELIMINARY meeting of the Dublin Sanitary Commission was held on the 7th inst., and arrangements were made for proceeding with the inquiry at once. Meanwhile, advertisements have been issued inviting all who think that they can contribute useful information to the Commission to send in their names.

DR. CHARLES P. TENANT, of Portnard, in the County Limerick, lost his life last week by taking a draught of carbolic acid by mistake instead of spirits which he had in the same pocket.

WE understand that the Governors of the City of Dublin Hospital, at their meeting on the 1st inst., decided to establish a nursing establishment of their own and dispense with the service of the nursing institute, which has heretofore catered for the requirements of the hospital.

PERSONAL.

DR. W. PASTEUR, F.R.C.P., Lond., has been appointed a Lecturer on Medicine in the Middlesex Hospital Medical School.

DR. CHARLES PORTER has been appointed Medical Officer of Health for the county of Shropshire in the place of the late Dr. W. N. Thurstfield.

DR. J. F. J. SMITH will deliver to-night (Wednesday) the Annual Oration of the Hunterian Society at the London Institution, Finsbury Circus, E.C.

SIR MICHAEL FOSTER has been elected Parliamentary Representative of the University of London by a large majority. We congratulate him upon this well-merited distinction.

DR. MARIO NASCIMENTO, a Portuguese doctor, lately Mayor of Laurenço Marques, has volunteered his services in the British ambulance in Natal, and has been accepted.

DR. JACKSON, one of the few medical men who could boast of the possession of a castle, has just lost Billister Castle, in Northumberland, by fire. Fortunately no loss of life was caused.

DR. RONALD ROSS writes to the *Times* to establish his claim to priority over certain Italian observers in the cultivation of the parasite of malaria in human beings and birds.

DR. JOHN BEDDOE and his wife have furnished six cottages at Bradford-on-Avon for the reception of convalescent women and girls, who will be received in return for a nominal payment weekly.

DR. JAMESON, Director-General of the Army Medical Service; Surgeon-Lieutenant Colonel Sloggett, and the Assistant-Surgeons and Dressers of the Imperial Yeomanry Hospital, were presented to H.R.H. the Prince of Wales, at Marlborough House, on Friday last.

PROF. BOYCE, of University College, Liverpool, has been reappointed Municipal Bacteriologist to the City, subject to a month's notice. An amendment providing for a year's notice was withdrawn, although a month's notice certainly seems very short for a post of this importance.

DR. WEATHERS, Police Surgeon for Sheffield, has volunteered for service in South Africa. He is a well known shot, and can ride well, and the Guardians, in consideration of his patriotic spirit, have decided to keep his appointment open until his return from the seat of war.

MR. WILLIAM HENRY POWER, principal Medical Officer to the Local Government Board, has been appointed a member of the Royal Commission on Sewage Disposal, vice Sir Richard Thorne Thorne, deceased. Sir Thomas Lauder Brunton, M.D., F.R.S., had the honour of Knighthood conferred upon him by Her Majesty the Queen, at Osborne, on Friday last.

WE learn with satisfaction that Mr. G. J. Johnston, Surgeon to the City of Dublin Hospital, who had been infected with diphtheria is, under the care of Dr. Parsons, making steady progress. Mr. Johnston received the infection, which was afterwards diagnosed by bacteriological examination, when operating for tracheotomy in the hospital. We hope for his early convalescence.

DR. MACWEENEY, Professor of Pathology in the Catholic University, and Pathologist to several Dublin Hospitals, and Examiner in the same subject at the Royal University, has been appointed to be Bacteriologist to the Local Government Board for Ireland. This is the first time that such appointment has been made for Ireland, though the analogous position has existed in England for some years. One of his chief duties will be to be responsible for the purity of the calf lymph now being issued by the Irish Board for general vaccination in Ireland.

MR. CHARLES STONHAM, F.R.C.S., Surgeon to the Westminster Hospital and Surgeon-Captain in the Middlesex Yeomanry Cavalry, has been appointed Senior Surgeon to the Imperial Yeomanry Hospital, and will shortly proceed to the front accompanied by a staff of dressers. During his absence from the Hospital the Lectures on Surgery will be delivered by his colleague, Mr. Walter Spencer, M.B., F.R.C.S. The staff will be somewhat short-handed in consequence of the departure of Mr. Stonham and Mr. Turner, and it is probable that one or more temporary assistant surgeons will be appointed. Many of the Hospitals are similarly situated, and there is a good opening for junior surgeons of Hospital rank.

Scotland.

[FROM OUR OWN CORRESPONDENT.]

EDINBURGH AND A BASE HOSPITAL FOR SOUTH AFRICA.—The surgical section of the profession in Edinburgh is at present much interested in the proposed formation of a base hospital to contain 100 beds, and to be entirely officered by surgeons and nurses from Edinburgh, for South Africa. The Lord Provost of the City, who has shown the best form of patriotism since the war began, obtained from the War Office an assurance that the offer of a hospital from such a centre of medical teaching as modern Athens would be most acceptable. At present no details of the proposed scheme have transpired, but as Professors Chiene and Annandale and Dr. Joseph Bell are taking a keen interest in it, and as surgical experts are numerous in Edinburgh, provided the matter of expense can be arranged there should be no difficulty in the way in regard to a staff. Edinburgh is largely represented at the front by combatants, commissioned and non-commissioned, but as yet has not supplied any surgical unit, apart from her graduates in the Royal Army Medical Corps.

FUNERAL OF THE LATE PROFESSOR SIR THOMAS GRAINGER STEWART.—On Wednesday last the funeral of Sir Thomas Grainger Stewart took place, the preliminary service being held in St. George's Church (with whose affairs the late professor was for long officially connected), prior to the final ceremony in the Dean Cemetery. The members of the medical profession in Edinburgh were present in large numbers to show a last token of their respect for one who had so long occupied such a prominent position among them, and had so ably discharged his duties. The Senatus of the University, the Royal College of Physicians of Edinburgh, the Medical Missionary Society, and the Students' Representative Council attended officially, while included among the senders of wreaths were the annual Presidents of the Royal Medical Society, the Students' Union, the infirmary residents, the physicians, students, and nurses of his infirmary wards, and the students' attending the class of Practice of Physic in the University, the numbers of these tributes of esteem coming from undergraduate sources testifying to the regard felt by the medical students at the University of Edinburgh towards their late teacher.

THE VACANT CHAIR OF THE PRACTICE OF PHYSIC IN THE UNIVERSITY OF EDINBURGH.—The Curators of the University of Edinburgh will have shortly thrown upon them the unenviable task of deciding upon whom the Chair of the Practice of Physic, rendered vacant by the recent death of Sir Thomas Grainger Stewart, shall be conferred. Among the many worthy physicians who will certainly become candidates for the post, which has before now been termed the "blue riband" of the teachers of medicine, it must prove an onerous task to weigh impartially the numerous pros and cons, the individual merits, and the promises for the future presented them.

At present we know of three certain candidates, John Wyllie, M.D., F.R.C.P.E., M.R.C.S., LL.D.; Bryon Bramwell, M.D., F.R.C.P.E., F.R.S.E.; and George Gibson, M.D., D.Sc., F.R.C.P.E., F.R.S.E., given in order of seniority. All three have an established reputation far beyond the limits of their own sphere of labour, all have conducted extra-mural classes upon Practice of Physic with success; for many years have or have had infirmary posts, and have published various works in medicine of world-wide fame.

The principal question will come to be whether a professorial chair is best filled by one who has passed the years of middle life, and has achieved success which his age suggests may be continued, but will probably not be surpassed, or by the middle-aged, already successful, with a promise of increased ability in the future.

We understand that the official staff at the Royal Naval Hospital, Stonehouse, is to be increased by one Deputy-Inspector General, and one more surgeon.

Manchester.

[FROM OUR OWN CORRESPONDENT.]

THE FUTURE OF THE ROYAL INFIRMARY.—The old problem is ever new. Men and years come and go, and the ancient hospital stands, and we "muddle through," hoping for better times. But new buildings, adequate equipment, sufficient endowment, remain dreams of the future. Professor Leech has recently contributed important articles to the *Manchester Guardian* in a strenuous effort to answer the question, "How should the additional accommodation required at the Manchester Royal Infirmary be provided." He brings a grave indictment against the present building clearly indicating its present deficiencies, and the unavoidable crippling of the work of the institution. The main departments of the hospital are not now in size or equipment fitted for the claims upon them, and great additions and changes are required, patients are discharged from the infirmary before they are fit to go out, in order to find place for others more seriously ill. A certain number of patients have to be sent to the Union hospitals because the necessary requirements for their treatment at the infirmary cannot be provided. The admission into the wards of patients suffering from accidents has been greatly restricted. Patients suffering from serious ailments requiring admission into the Infirmary have often to wait a long time before they can be admitted, and sometimes suffer gravely in consequence.

Instances from time to time occur in which serious accidents and cases urgently ill are brought to the Infirmary, requiring immediate admission, but owing to want of room they have to be taken elsewhere. Operations are sometimes performed in the Infirmary on patients coming to the out patients' department, although the pressure on the beds prevents them being received as in-patients. This is some of Dr. Leech's evidence of the need for immediate action. He advocates re-building on a site outside the city. The annual general meeting of trustees was held on Friday last, at which it was explained that the negotiations with the Corporation respecting the sale of the Infirmary site had completely broken down.

The following resolution was then adopted:—"That the trustees hereby authorise the board of management to appoint a committee to deal with the last resolution of the Medical Board as given in the annual report, with a view to ascertain (1) whether or not a hospital suitable in every way can be built on a plan other than the pavilion; and (2) if this be decided in the affirmative by such committee, that the board of management be authorised to take steps to obtain suitable plans and estimates, and to incur all necessary expenses in connection therewith." This indicates that no immediate steps are likely to be taken in meeting the urgent necessities of the sick poor, and providing means for the adequate teaching of medical science in Manchester for some time to come.

MEDICAL SOCIETY OF LONDON.

THE meeting on Monday last was a "clinical evening," with an unusually rich supply of living specimens.

Mr. Wallis showed a small boy, who, after recovery from tuberculous peritonitis, developed acute intestinal obstruction, which had been relieved by bringing out a coil of small intestine. This had prolapsed, and the discharge had caused maceration of the skin. He excised the piece of intestine, suturing the divided ends, and solid union had resulted.

Mr. Jaffrey showed an interesting case of urticaria pigmentosa in a child, eighteen months old, the site of the wheals being marked by a brownish discoloration.

Dr. Chapman showed an obscure case of congenital cyanosis without morbus cordis, and Sir Hugh Beever showed a man, set 23, who exhibited in a marked degree the phenomenon known as *pulsus bisferiens*.

Mr. Barker having shown a case of congenital dislocation of the hip and discussed the value of forced

reduction, Dr. Ewart and Dr. Willock showed contrivances having for object the application of pressure to the thorax during expiration for the relief of emphysema.

Mr. Battle showed a man, æt. 29, with a curious deformity and tumour of the left thigh which he took to be due to osteitis deformans affecting only one bone.

Dr. W. J. Hadley showed a child with osteo-arthritis following repeated attacks of rheumatic fever with the characteristic enlargement of the spleen and lymphatic glands. He also showed another girl who exhibited some rare manifestations of rheumatism.

Mr. W. McAdam Eccles showed two cases illustrating variations in inguinal herniæ due to abnormal descent of the testis. Case 1. A man, æt. 23, with imperfect descent of both testes and a large interstitial hernia which was treated by the application of a truss and had almost disappeared. The right testis lay in the inguinal canal just above Poupart's ligament, and the left was just protruding through the internal abdominal ring. Case 2. A man, æt. 42, presented a well-marked cruro-scrotal hernia, i.e., an inguinal hernia which, escaping from the superficial abdominal ring, had missed the entrance to the scrotum and had stretched to the skin forming the junction of the thigh and the scrotum, the most external covering of the hernia being therefore ordinary skin.

Mr. Barker pointed out that in some cases at any rate the relations and position of the testis had nothing to do with the development of the hernia.

Lastly, Dr. S. Mullick showed a man, æt. 22, with transplantation of the viscera, the heart and stomach being on the right side and the liver on the left.

Obituary.

MR. THOMAS PURCELL, M.R.C.P., OF DUBLIN.

WE regret to announce the death of this respected practitioner, which took place last week at his residence in Dublin. He was the eldest son of the late Judge Purcell, who acted for a long period as standing counsel to the Irish Medical Association, and Mr. Purcell took an active part for many years in the administration of the Association. He received in 1863 his first qualification as licentiate of the Irish Colleges of Physicians and Surgeons, and took the higher diploma of the latter body at a later date. He was for many years, until his death, a medical officer of one of the South Dublin Dispensaries, which coveted position becomes vacant by his death.

Correspondence.

We do not hold ourselves responsible for the opinions of our correspondents.

NEALE'S DIGEST.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—No doubt most of your readers are aware that Dr. Neale has recently published the Supplement to his "Medical Digest," which completes and brings down to date that admirable guide to the British medical literature of the last fifty years: but it is not likely they have any idea of the enormous and unremitting labour this self-imposed task has cost the compiler. The work of making his index, and preparing it for the press has involved an average of four hours per day for more than fifty years! This labour has not only been without remuneration, for the publication of the Digest has never been profitable, but it has been carried on year after year at great cost to Dr. Neale, who, with rare determination has cheerfully persevered in a task which he originally undertook for the benefit of science and of his profession rather than for his own pecuniary advantage.

It seems to the undersigned that it would be unbecoming to the profession he has worked for if Dr. Neale's labours were allowed to pass unrecognised, and they have, therefore, decided to invite the members of

the profession throughout the British Empire to contribute to a fund which will enable them to present Dr. Neale with a suitable testimonial, as a recognition by his professional brethren, of his long continued and invaluable labours on their behalf. Obviously, it would be premature to discuss the form of the testimonial until the amount of the contributions can be ascertained, but all the subscribers will be communicated with before a decision is arrived at.

W. S. CHURCH, President of the Royal College of Physicians.

WM. TURNER, President of the General Medical Council.

H. G. HOWSE, Senior Vice-President of the Royal College of Surgeons.

THOMAS BRYANT, President of the Royal Medical and Chirurgical Society.

R. DOUGLAS POWELL, President of the Clinical Society.

W. WATSON CHEYNE, President of the Pathological Society.

FREDERICK T. ROBERTS, President of the Medical Society.

ALBAN DORAN, President of the Obstetrical Society.

W. H. BROADBENT, President of Medical Graduates College and Polyclinic.

HENRY POWER, President of the New Sydenham Society.

JONATHAN HUTCHINSON, Hon. Secretary of the New Sydenham Society.

Subscriptions may be sent to Mr. J. Y. W. MacAlister (Librarian of the Royal Medical and Chirurgical Society), 20, Hanover Square, London, W. It will save him much trouble if cheques are made payable to "Bearer" and crossed "National Provincial Bank—Neale Testimonial Account."

THE IRISH CONJOINT EXAMINATIONS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—May I be permitted to correct a statement in the current number of your journal, that the report of the Committee of Management on the autumn examinations has been held over for nearly three months. It is not possible to make up the statistics of an examination till said examination shall have concluded. The examinations to which the report relates were not completed till November 10th, and the report was forwarded to the Royal College of Surgeons on December 13th—just one month, not three.

There was no meeting of the committee between November 20th and December 11th, so that the report was presented and passed at the earliest possible moment.

I am, Sir, yours truly,

GREENWOOD PIM, Sec.

Dublin, February 9th, 1900.

THE ALLEGED FAILURE OF ISOLATION HOSPITALS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—One cannot help wondering why you went out of your way to make such an effort to break my poor butterfly on the editorial wheel.

Your "review" of my hapless pamphlet appears more like a personal attack than a criticism. You characterise the language used as odd, and proceed to justify your assertion by making a gross misquotation, which is very odd indeed.

"Serious argument," you say, "is conspicuous by its absence." Oh! In the *resumé* on page 12 I summed up the case against hospital isolation thus:—

1. The danger of secondary infection.
2. The failure as instanced by "return cases."
3. The high mortality of "return cases."
4. The danger of "catching" other diseases.
5. The injury inflicted on children by removing them from home influences.
7. The demoralisation which follows in the train of rate-supported free hospitals.
8. The fact that the period during which houses remain centres of infections, was trebled, quadrupled, and sometimes sextupled by "return cases."
9. The utter and complete failure to control epidemics.

I also gave our experience in Nottingham of the stamping-out process, which is as follows:—We began in 1883 with 428 cases, in 1889 we had 1,047, in 1895 1,250, and up to the end of November last year 2,383.

If this be not "serious argument" in your opinion I cannot help it. You say "the author propounds no alternative scheme." I am surprised at this. If a man brings to demonstration a particular scheme is it contended that he is bound to provide an alternative scheme?

I protest against your discovering my supposed motive. In this you go beyond the bounds of legitimate criticism. My pamphlet appeared in December. Everybody knows that the municipal elections are over and forgotten by the end of November; then how can it be said that my pamphlet was written for electioneering purposes.

The failure of isolation hospitals is everywhere meeting with wide recognition, and it affords me astonishment that you seem to be unaware of the fact.

I am, Sir, yours truly,

EDWD. DEAN MARRIOTT.

Nottingham, February 7th, 1900.

[As Dr. Marriott does not refer us specifically to the alleged "gross misquotation," we are unable to verify or explain. Dr. Marriott's conclusions are clear enough, but when we commented on the absence of "serious arguments," we referred to the grounds on which those conclusions were advanced. The latter we still regard as quite inconclusive. With reference to his complaint that we suspected a desire to influence local politics we believe we are correct in saying (the pamphlet having gone the way of most pamphlets) that the author wound up by stating that it remained with the voters to remedy a condition of things which he regarded as an iniquity. This surely constitutes an appeal to the electorate!—Ed.]

The Royal University of Ireland.

At a full meeting of the Senate, held on Thursday last, a resolution of sympathy with the Marquis of Dufferin and Ava, K.P., Chancellor of the University, on the death of his son, the Earl of Ava, was unanimously adopted.

A committee was appointed to examine the financial state of the University, with the view of ascertaining how far it would be possible and desirable to appoint additional and external examiners; and the standing committee were requested to report as to the qualifications to be required for honorary degrees.

The following gentlemen were recommended to the Vice-Chancellor for nomination to the two commissions in the Royal Artillery placed at his disposal by the Secretary of State for War:—(1) C. W. Nixon, (2) S. Perry, and, in case either of these gentlemen fails to qualify, (3) H. J. Nolan-Ferrall.

The following appointments were made:—

FELLOWS (for five years).—Rev. Henry Browne, T. W. Dougan, C. H. Keene, James MacMaster, Thomas P. O'Nowlan, Philip Sandford, Thomas Arnold, Rev. J. Darlington, S. J. MacMullan, G. F. Savage-Armstrong, William F. T. Butler, E. Cadic, V. Steinberger, Rev. E. Hogan, Rev. T. A. Finlay, William Magennis, John Park, William P. Coyne, Alfred C. Dixon, J. J. Gibney, H. C. McWeeney, John Purser, William B. Morton, Thomas Preston, J. H. Stewart, E. A. Letts, Hugh Ryan, B. O. Cunningham, and George Sigerson.

MEDICAL FELLOWS (for three years).—A. Birmingham, J. P. Pye, J. Symington, J. J. Charles, D. J. Coffey, John I. Lynham, P. J. Hayes, and Sir Thornby Stoker.

EXAMINERS (for the year 1900).—Douglas Hyde, Rev. R. H. F. Dicky, W. J. Carbery, Rev. R. J. Semple, Rev. G. Woodburn, William Graham, Alexander J. M. Blaney, Marcus M. Hartog, Richard J. Anderson, Alexander Jack, M. F. Fitz Gerald, Annie W. Patterson, Joseph Smith, Charles F. Doyle, William N. Watts, William A.

Houston, William Bergin, Joseph F. O'Carroll, James A. Lindsay, William H. Thompson, E. J. McWeeney, J. Lorrain Smith, John W. Byers, Alfred J. Smith, C. Y. Pearson, Antony Roche, F. J. B. Quinlan, William Whitley, Arthur W. Sandford, Louis Werner, and Sir Charles A. Cameron.

At a public meeting of the University the Degree of Bachelor of Arts was conferred on William Moloney Margaret College (S. J.), Limerick.

Royal College of Surgeons in Ireland.

A MEDICAL Students Guide for the coming session has just been issued by the College. The preliminary examinations are held in March and September. The conjoint professional examinations are held in the months of April, July and October.

The Conjoint Diploma in State Medicine.—Held the first Tuesdays in February, May, and November. Fee, £10 10s.

The Fellowship Examination.—Held the third Mondays in February, May, and November. Fee, £26 5s.

The Licence in Surgery for Registered Practitioners.—Held the first Mondays in February, May, and November. Fee £26 5s.

The Licence in Dentistry.—Held second Mondays in February, May, and November. Fee Primary, £10 10s.; Final, £10 10s. Entries for all examinations must be made fourteen days previously.

The Guide can be had free on written application to the College, Stephen's Green, Dublin.

Medical Libel Suit.

AN action was tried at Kilmsnock last week, in which Dr. Beveridge, of Hurlford, claimed £1,000 damages against Dr. Baxter, also of Hurlford, for slander contained in a report sent by the defendant to the Riccarton Parish Council concerning the plaintiff's treatment of a child. The Sheriff found that the report was slanderous but privileged, but that the defendant had shown malice and want of justification, and he awarded £100 with costs.

THE anniversary dinner of the Medical Society of London will be held in the Whitehall Rooms of the Hotel Metropole on Thursday, March 16th, at 7 o'clock. Tickets may be obtained of the honorary secretaries, Dr. James Calvert and Mr. F. C. Wallis, at 11, Chandos Street, W.

Lectures at the Royal College of Surgeons of England.

THE following are the lectures arranged for the current quarter. Each is delivered at the hour of four o'clock, and all are open to members of the profession on presentation of visiting card, whether Fellows of the College or not. Mr. E. Treacher Collins, F.R.C.S.: Three lectures on "The Anatomy and Pathology of the Eye," the first of which was delivered on Monday last; the remaining two will be delivered to-day and on the 16th inst. Mr. B. G. A. Moynihan, F.R.C.S.: Three lectures on "The Anatomy and Pathology of some Rarer Forms of Hernia," February 19th, 21st, 23rd. Professor Arthur Keith, F.R.C.S.: Three lectures on "The Results of an Investigation of the Anatomy of Man and Higher Primates to determine more accurately the Relationship of Man to Living and Extinct Forms," February 26th, 28th, March 2nd. Professor A. W. Mayo Robson, F.R.C.S.: Three lectures on "The Surgery of the Stomach," March 5th, 7th, 9th. Professor C. Stewart, LL.D., F.R.S.: Six lectures on "The Protection and Nourishment of the Young in Plants and Animals," March 12th, 14th, 16th, 19th, 21st, 23rd.

Army Medical Service.

The following is an official list of successful candidates for commissions in the Royal Army Medical Corps at the recent examination in London arranged in the order of merit:—

Biggan, T.	2554	Adye-Curran, W. J. P.	2185
Richardson, H.	2532	Powell, J. L.	2156
Carr, C. H.	2490	Argles, R. L.	2080
Baker, W. L.	2462	Foster, J. G.	1975
Cotton, F. W.	2420	Lauder, F. P.	1970
Bennett, E.	2275	Ford, E. G.	1803
Parry, F. M.	2248	Walker, F. S.	1802
Dinnis, B. R.	2221	Purser, L. M.	1800
Twigg, J. S.	2185		

Notices to Correspondents, Short Letters, &c.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a distinctive signature or initials, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

LOCAL REPORTS AND NEWS.—Correspondents desirous of drawing attention to these are requested kindly to mark the newspapers when sending them to the Editor.

READING CASES.—Cloth board cases, gilt lettered, containing twenty-six strings for holding the numbers of THE MEDICAL PRESS AND CIRCULAR, may now be had at either office of this journal, price 2s. 6d. These cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

ORIGINAL ARTICLES or LETTERS intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

REPRINTS.—Authors of papers requiring reprints in pamphlet form after they have appeared in these columns can have them, at half the usual cost, on application to the printers before the type is broken up.

DR. PERCY LODGE.—We hope to have space for your case in our "Clinical Records" next week.

FEMALE MEDICAL STUDENTS IN PARIS.

THERE are actually 128 female medical students at Paris, of whom 91 are Russians, 29 French, 5 Roumanians, 2 Germans, 1 Swiss, and 1 British. In Paris women are placed absolutely on the same footing as men, and their presence has long since ceased to give rise to the ill-bred manifestations of dislike which characterise the conduct of male students in this country when mixed classes are attempted.

DR. R. GLASGOW PATTISON'S case is marked for early insertion.

DR. ALEXANDER DUKE.—If possible in our next.

DR. MERRIN.—Your communication was too long for publication in the present number, but we have marked it for early insertion.

QUEERENS.—The matter will receive editorial attention at the first opportunity. The time is not yet ripe.

DR. McV L.—Your suggestion has been anticipated, and a fund of over £12,000 is being raised in Edinburgh for the equipment of a Scottish Hospital for South Africa. Over half the sum has already been promised.

M. S.—Dr. Springer's suggestion bears on "epiphysal" culture and not, as most of the lay journals have described it, "epiphysical" culture.

DR. E. HOPE (Liverpool).—Your letter will receive attention in our next issue.

PONDEROUS INDEED!

THE Paris correspondent of the *Refrère* is responsible for the following *jeu d'esprit*:—"Is there one single man," he asks, "who would dare to be ill with this solemn fact in his face? Permission to act as a doctor has been granted by the Paris Faculty to Mlle. Marie Kritchewsky-Gochbaum, who se treatise on 'ankylose articulaire progressive et generalisee on synarthrophysae' struck them as being excellent. Fancy sending out a servant-girl with that weight to carry, and to bring back to your bedside the lady who did it, and was still going well and strong!" Bravo, *Refrère*! but all the same it would not be safe to gauge the male doctor by the ponderosity of his scientific treatises.

Meetings of the Societies and Lectures.

WEDNESDAY, FEBRUARY 14TH.

HUNTERIAN SOCIETY (Theatre of the London Institute Finsbury Circus) - 8.30 p.m. Dr. F. J. Smith: The Influence of Modern Medicine on Surgery Annual Oration.

THURSDAY, FEBRUARY 15TH.

HARVEIAN SOCIETY OF LONDON (Stafford Rooms, Tichborne Street, Elgware Road) - 8.30 p.m. Papers:—Dr. G. F. Blacker: Experiences in Feeding Delicate and Premature Children with Modified Milk. -Mr. F. Jaffrey: Calculous Suppression of Urine treated by Operation.

FRIDAY, FEBRUARY 16TH.

EPIDEMIOLOGICAL SOCIETY OF LONDON (11, Chandos Street, Cavendish Square, W.) - 8.30 p.m. Paper:—Dr. E. W. Hope: Insanitary Property and Workmen's Dwellings in Liverpool.

Appointments.

ANDERSON, F. T. M. D. BRUX, F.R.C.S. Ed. Honorary Medical Officer to the Barnstaple and North Devon Dispensary.

BEGGS, J. E., B.A., M.D., D.P.H. Cantab. Medical Superintendent to the Grove Fever Hospital, Tooting, S.W.
BIRKETT, G. T., L.R.C.P., L.R.C.S. Ed. Assistant Medical Officer for the Calford Sanitary District of the Lewisham Union.
GREENWOOD, T. PARKER, M.B. C.M., B.Sc. Edin. Assistant Medical Officer to the Three Counties Asylum, Hitchin.
JONES, W. WATKINS, M.D., C.M. Ed., D.P.H. Camb. Medical Officer of Health to the Gelligerr and Rhigos District.
MORGAN, FREDERICK CHARLES, L.R.C.P. Lond., M.R.C.S. Resident Medical Officer at the Eastville Workhouse, Bristol.
NOBLE, H. PERCY M.B., B.S. Lond., M.R.C.S. Assistant Anaesthetist to the Middlesex Hospital.
PORTER, CHAS., M.D. Irel., M.R.C.S. D.P.H. Cantab. Medical Officer for the County of Salop.
POTTS, W. J., M.D. Lond., L.R.C.P., M.R.C.S. Medical Superintendent of the Parish Infirmary, Bethnal Green.
ROBINSON, ARTHUR HENRY, M.D. Durh., M.R.C.S., D.P.H. Camb. Medical Superintendent of the Islington Infirmary, Highgate.
ROW, C. M., L.R.C.P. Lond., M.R.C.S. Medical Officer for the Four Sanitary District of the Battle Union, Sussex.

Vacancies.

Bath General or Royal Mineral Water Hospital, Bath.—Resident Medical Officer, unmarried. Salary £100 per annum, with board and apartments.
Brecon Infirmary, South Wales.—Resident House Surgeon, unmarried. Salary £90 per annum, with furnished apartments, board, all found except beer, attendance, fire, and gas.
Burton-on-Trent Infirmary. House Surgeon. Salary commencing at £150, with furnished rooms in the Infirmary, and coals and gas free.
City Asylum, Nottingham.—Second Assistant Medical Officer, unmarried. Salary £150, with board, apartments, and washing.
Consumption Hospital, Ventnor.—Assistant Resident Medical Officer to the Royal National Hospital for Consumption. Salary £100, with board and residence. Immediate application to Dr. Parry. (See Advt.)
Dental Hospital of Ireland.—Two anaesthetists. Immediate applications to N. A. Shea, Esq., J.P., at the Hospital, Lincoln Place, Dublin. (See advt.)
Great Northern Central Hospital London.—Assistant Anaesthetist for six months subject to reappointment, with a small honorarium. Applications to be addressed to L. H. Glenton-Kerr, Esq. (See Advt.)
General Infirmary at Gloucester and the Gloucestershire Eye Institution.—House Surgeoncy. Salary £100 per annum, with board, residence, and washing.
Hants County Asylum, Fareham.—Third Assistant Medical Officer, unmarried. Salary commencing at £125 per annum, with furnished apartments board, washing, and attendance.
Hulme Dispensary, Dale Street, Stretford Road, Manchester.—House Surgeon. Salary £130 per annum, with apartments, attendance, coal, and gas.
Kent County Ophthalmic Hospital, Maidstone.—House Surgeon. Salary £100 per annum, with board and lodging in the Hospital.
Mercer's Hospital, Dublin. Resident Medical Officer. Applications to the Registrar of the Hospital. (See Advt.)
Mercer's Hospital, Dublin.—Vacancy on the Surgical Staff. Applications to the Registrar of the Hospital. (See Advt.)
Nottingham General Dispensary.—Assistant Resident Surgeon. Salary £140 per annum, all found except board; unmarried.
Workshop Dispensary Hospital.—Resident Surgeon. Salary £120 per annum, rooms, coal, gas, furniture, and housekeeper provided. Apply to Mr. Charles A. Whall, Workshop.

Births.

DAMAN.—On February 6th, at Oakhurst, Dorridge, Knowle, Warwickshire, the wife of Karl A. Daman, L.D.S., of a daughter.
GLADSTONE.—On February 7th, at Penryn, Cornwall, the wife of Arthur Edward Gladstone, B.A. Cantab., M.R.C.S. Eng., L.R.C.P. Lond., of a daughter.
KIRBY. On February 5th, at Maesteg, Glamorganshire, the wife of Walter Kirby, L.R.C.P. Edin., L.R.C.S. Edin., of a daughter.
PARKER.—On February 6th, the wife of G. D. Parker, M.B., Westwood, Manchester, of a son.
PORTER.—On February 7th, at 9C, Edith Road, W. Kensington, the wife of Robert Ibbetson Porter, M.A. Oxon, M.R.C.S., L.R.C.P., of a son.

Marriages.

BRACE-BROCKMAN TRAVERS.—On February 10th, at the Cathedral, Bombay, India, Capt. V. G. Drake-Brockman, Indian Medical Service, 5th son of W. Drake-Brockman, Esq., P.W.D., N.W.P., India (retired), of Cheriton, Bournemouth, to Julia Beatrice, youngest daughter of Lt. Col. J. B. Travers, of Southampton.
HUDSON-CROSSE.—On February 8th, at the Cathedral, Norwich, Edmund Hudson, M.R.C.S., L.R.C.P., third son of the Rev. W. Hudson, of Eastbourne, to Lucie Agnes, youngest daughter of the Ven. Archdeacon Crosse, Canon Norwich Cathedral.
STABB-HUNTLEY.—On February 5th, at the Church of SS. Philip and James, Cheltenham, William Wilking Stabb, M.D., of Torquay, to Mary Gertrude, only daughter of the Rev. Osmond C. Huntley, of Boxwell, Gloucestershire.

Deaths.

GILL.—On February 6th, at 8, Chester Place, Regent's Park, London, Walter Battershell Gill, M.D. Lond., F.R.C.S. Ed., aged 77.
OAKLEY.—On February 4th, at Lydart, Peppys Road, New Cross, S.E., Charles Edward Oakley, L.R.C.P., L.R.C.S. Edin., and L.M., L.F.P.S. Glasg.
WELLBORNE.—On February 2nd, at Brixton, Richard Wellborne, M.D., in his eighty-fifth year.

The Medical Press and Circular.

Clinical Lecture ON THE TREATMENT OF PLEURISY.

By PROF. G. DEBOVE.

THE treatment of pleurisy, which forms the subject of this lecture, may be *pathogenic*, that is to say, directed to the cause of which pleurisy is but an effect, or on the contrary, *symptomatic*, that is to say, to act upon the pleurisy itself by medical and surgical means. I will not insist on the *causal* treatment which is that of the various maladies of which pleurisy is but a manifestation. It will suffice for me to point out to you the importance of it by two examples. In the immense majority of cases pleurisy is of tuberculous origin, and its treatment is merged into that of pulmonary phthisis. Sometimes, however, the pleurisy is of rheumatic origin, and in this event the treatment by salicylate of soda is indicated. Nevertheless in treating the cause, the medical treatment of the pleurisy itself should not be neglected. This treatment consists mainly in *counter-irritants*, *drastics*, and *diuretics*. The counter-irritants should be applied to the chest on the side affected and particularly over the seat of pain. They rapidly attenuate, and may even subdue two important phenomena: pain and dyspnoea. You may choose between dry cupping, wet cupping, leeches, chloride of methyl spray, sinapisms, or the actual cautery. Wet cupping should be reserved for cases in which the pain is very severe. Under the same circumstances the blister, which constitutes the classical medication, may also be employed. I am not, however, a great partisan of the blister for the following reasons:—It has two effects, one common to every revulsive, the other due specially to the action of the cantharides; now the action of the cantharides upon the economy appears to me to be harmful, for it is apt to give rise to boils, cystitis, and even nephritis. Moreover, if cantharides really act upon the effusion, it is not in the form of a blister that it should be employed, but in the state of cantharidine, or of cantharidate of potash. In addition, the blister presents certain inconveniences and even dangers, not to speak of the cicatrix which it leaves on the skin, it produces a wound which offers an impediment to auscultation of the patient, and it prevents our practising thoracentesis under aseptic conditions, and might even become the starting point of infection. In vain has the blister been defended by pretending that it favours absorption of the fluid, for that fact has by no means been confirmed by clinical experience. In justification of the employment of drastic purgatives in pleurisy, the following explanation has been given: the loss of serous liquid provoked from the intestine must produce concentration of the blood, which makes up for the loss by borrowing from the serum of the effusion the liquid elements which it needs. This pathology is somewhat ingenuous, but we would not offer much

objection if it were in accord with clinical observation, which proves to us that drastics fatigue the patient and never favour absorption of the effusion. Based on the same reasoning, diuretics have been recommended, but these again have never been seen to cure a pleurisy, and it must not be forgotten that a certain number of diuretics have an injurious influence on the kidney. Since counter-irritants, drastics, and diuretics cannot bring about the absorption of the liquid, it only remains for us to evacuate the fluid by surgical means, that is to say, by thoracentesis.

This operation, however, should not be practised in all patients; it should not be resorted to, for instance, in pleurisy supervening at the last stage of consumption, in purulent infection, or uræmia, unless the dyspnoea is very marked.

Age is not a counter-indication to thoracentesis; it has been practised with success on children under a year old and on very aged persons. If the liquid does not exceed a pint the operation is not necessary; if, on the contrary, the effusion amounts to a quart, it should be done, especially if there is much dyspnoea.

To avoid syncope before or after the operation, I am in the habit of operating the patient in the horizontal position and not sitting up as is usually preferred.

Let us suppose that thoracentesis is decided upon, what will be the *modus operandi*? In the earlier surgical attempts made to evacuate the fluid in pleurisy, pleurotomy was practised in the same way that we do it to-day for purulent pleurisy, but the results were disastrous. Morbid germs were introduced through the wound, transforming a serous effusion into an empyema. To-day, by observing with care the rules of asepsis, this danger can be vastly diminished, but it is useless to expose the patient to the risk, as we can operate without danger by means of the aspirator introduced into practice by Professors Potain and Dieulafoy. These aspirators have the advantage of permitting the use of fine needles, which frighten the patient less, produce less suffering, and do not leave fistulae, as when large trocars were used for purulent pleurisy.

In order not to introduce pathogenic organisms into the pleura where they would find a favourable milieu for their culture, the needle must be sterilised by passing it rapidly in a flame and placing it in boiling water for a few minutes. The skin must be carefully disinfected over the region of the little operation so that the point does not carry with it the germs which, under ordinary circumstances, are found on the surface of the skin; the parts should first be washed with soap and water, then with ether, and finally with a solution of corrosive sublimate. The puncture should be made in the fifth intercostal space in the mid axillary line. At this point the thoracic wall is comparatively thin, the ribs are sufficiently separated from each other, and one is sure to be far enough from the diaphragm not to run the risk of wounding it, while the heart and the large

vessels are out of harm's way. It has been recommended to pass the trocar a short distance under the skin before penetrating, in order to destroy the parallelism between the cutaneous wound and the pleural opening, so as to render all oozing impossible when the instrument has been withdrawn, but this parallelism is sufficiently destroyed by the retraction of the thorax after the operation. The needle should be pushed in quickly, and as close as possible to the upper margin of the rib so as not to wound the intercostal artery or nerve which run along its lower border.

In spite of these precautions it may happen that no liquid escapes, to the disappointment and annoyance of the operator; this may be due to an error of diagnosis, or to the fact that the pleurisy is circumscribed, the needle passing outside of it. Many surgeons with the object of obviating the possibility of disappointment pass in an exploring needle before operating, and I see no reason to object to this practice.

Among the accidents which sometimes follow thoracentesis I may mention: Rapid reproduction of the effusion, its purulent transformation and albuminous expectoration.

The rapid reproduction of the effusion is not due to the operation, but to the persistence of the cause which produced the pleurisy. These effusions are ordinarily of tuberculous origin, and easily become purulent. The liability to purulent transformation of the liquid is one of the great drawbacks of thoracentesis. Those who object to thoracentesis on this ground, however, are only right in part. It is certain that if the trocar introduced into the pleura morbid germs, the condition would be eminently favourable for their development. But it must not be forgotten that many effusions, notably those of tuberculous origin, are at first serous, and then spontaneously become purulent.

Albuminous expectoration follows in cases in which too great a quantity of liquid had been rapidly evacuated. The accident may assume three forms: slight, severe, grave. In the first named there will be dyspnoea, with continuous expectoration, accompanied by fits of coughing. In the severe form the expectoration is very abundant, the dyspnoea intense, auscultation reveals oedema of the lung. In the grave forms the patient succumbs rapidly to asphyxia. Many pathogenic hypotheses have been promulgated to explain the occurrence of albuminous expectoration, but it appears to be proved that it is the result of congestion of the lung, with acute oedema and serous invasion of the alveoli. The accident may be avoided by never withdrawing more than a quart of the liquid at a time. If the effusion be very abundant a second operation may be done on the following day, for thoracentesis is as benign as it is simple. There is, moreover, no objection to leaving a little liquid in the pleura, for this is sometimes very quickly absorbed without necessitating a second operation.

Among other accidents due to thoracentesis I may mention pneumothorax, wounds of the lung, cough, and thoracic pain. Pneumothorax is hardly to be feared. The introduction of a small quantity of air into the pleura during the operation is not attended by danger and is soon absorbed. A wound of the lung is not very important, but syncope is sometimes very serious when due to a too complete and too sudden evacuation of the fluid, producing rapid congestion of the lung and anæmia of the medulla as a consequence. The cough is dry and irritating, and so painful that the operator is obliged to stop. Sometimes intra-thoracic pain is produced which may become so severe as to render it necessary to suspend the operation. This pain is probably due to distension of the pleura when the compressed lung returns to its normal volume.

Original Communications.

INSTRUCTION IN OBSTETRICS AND GYNÆCOLOGY. (a)

By W. J. SMYLY, M.D., T.C.D., F.R.C.P.,

President of the British Gynæcological Society; Gynæcologist to the Adelaide Hospital.

IN this country, curiously enough, practical instruction in midwifery is generally of a most primitive description, owing chiefly to the paucity of well equipped Lying-in Hospitals, and this is the more remarkable since in comparatively insignificant towns on the Continent there are splendid Maternity Hospitals, superior to any to be found in this country, where the students are carefully instructed by professors of great learning and experience, assisted by an efficient staff of assistants. Clinical teaching can only be carried out efficiently in the wards of an hospital, but most of our students pick up what they can from attending a few women in their confinements in their own homes. What would be the position of medicine and surgery in this country if the only instruction given to students were a course of systematic lectures, and a few domiciliary visits with or without the assistance of their teachers.

As regards gynæcology the case is different. All our large hospitals possess a gynæcological department which together with special hospitals afford ample material for the practical study of women's diseases. These departments are well equipped and supplied with competent teachers, but the benefit which would otherwise be derived is nullified by the unpractical nature of the examinations. To the majority of students the chief object of study is to pass their examinations; to the diligent and ambitious to do it with credit, and rightly because their position in after life mainly depends upon their doing so. A student is well aware that in passing through that ordeal he will be brought to the bedside, and will have to diagnose the disease from which the patient is suffering. He cannot tell what part of the human body he may be called upon to investigate, but of one thing he is certain, that it will not be the female pelvic organs. He must therefore familiarise himself with the methods of examination in every other department of medicine and surgery, but the practical study of women's diseases he may safely neglect. I have found this in my own hospital work. My clinical lectures are well attended by the students, the examination of patients badly, and the operations hardly at all. I do not suggest that every student should have a practical examination in midwifery and gynæcology, though in other countries this is the case. In the McGill University, for example, a clinical examination in these subjects similar to that held in Medicine and Surgery, forms part of the final examination; but I do think that he should take his chance of such an examination, and it appears to me an anomaly that every student has to submit to a practical examination upon the eye, and no student is examined in this way upon the uterus. And this is the more remarkable because in no other branch of medicine is practical knowledge relatively more important than in this. The theory of midwifery and gynæcology is a limited subject and easily acquired, but the practical manipulations are exceedingly difficult and require much time and trouble. A practitioner who has passed his examinations with a minimum of knowledge can easily supplement it afterwards by study, but the *tactus*

(a) Abstract of the Presidential Address delivered before the British Gynæcological Society, February 8th, 1900.

eruditus can then only be acquired after much discredit to himself and possible injury to his patients.

MIDWIVES AND MONTHLY NURSES.

The education of midwives has received a large amount of attention, but is still in a most unsatisfactory condition. It is a lamentable fact that after upwards of a century of agitation nothing has been done to enforce women who undertake to attend others in labour to have any knowledge at all of their duties. During the past quarter of a century I have been brought much in contact with midwives, and as a class I have found them an honest, careful, respectable, and fairly efficient body of women. To this general rule, however, I have found exceptions, and have met with ignorant, drunken, and meddlesome women, who were a source of danger to their patients; and if this experience be multiplied by that of practitioners throughout the country, it represents a large number of ignorant, incompetent, and even immoral women. This is a condition of things which is a disgrace to our civilisation, and loudly calls for legislative reform. This question has before this been brought before our Society, and it is our duty, not only to press for reform, but so to influence the course of legislation that it may prove beneficial alike to the public and the medical profession. At the present time anyone may practise midwifery, and call themselves midwives. It should be our object to insure that in future only properly trained women should use this application, and that they should not overstep their duties by practising midwifery.

In an inaugural address as President of the Obstetrical Society in 1895, Dr. Champneys gave a clear and concise history of midwives in England, and the work of that Society in relation to their examination and registration, a history which could not be too widely circulated or too seriously considered by medical men in these countries at the present time. We should never forget, and we should not allow the public in the present agitation to overlook the fact that this movement for reform originated with, and has ever since found its most ardent supporters among the members of our profession. In 1616 Dr. Peter Chamberlain begged James I. "that some order may be settled by the State for the instruction and civil government of midwives." In his work, "A Voice in Ramah," he speaks thus:—"Because there was never any order for instructing and governing midwives, therefore there never must be; because multitudes have perished, therefore they still must perish; because our forefathers have provided no remedies, nor knew any, therefore we must provide none, though we know it." "These words," Dr. Champneys says, are unfortunately as true to-day as when they were written." In 1756, through the influence of Dr. Mosse, the Rotunda Hospital was incorporated by Royal Charter, and one of the chief objects named and reasons assigned for granting that Charter was "that by admitting and instructing in such hospital women who, after some time spent there, being duly qualified, may settle in such parts of our said kingdom as most stand in need of such persons, it will be a means of preventing the unhappy effects owing to the ignorance of the generality of country midwives. That by preserving the lives of so many infants who in all probabilities must otherwise perish it will increase the number of our subjects in our said Kingdom." In 1813 the Society of Apothecaries, in 1882 the British Medical Association, in 1890 the Midwives Institute, the Obstetrical Society and British Medical Association urged upon Parliament the necessity for legislation. A Select Committee of the House of Commons in 1892-93 recommended that a system of examination and registration of midwives should be established. I need not recall all the efforts made, and bills brought forward,

but hitherto in vain to cure what all admit is a deplorable evil.

The chief causes of past failures are, I believe:—

1. The apathy of the general public.
2. The opposition of a large part of the medical profession.
3. The exclusion of Ireland from all bills hitherto framed.
4. The difficulty of carrying any private bill through Parliament.

The first cause of failure is slowly but certainly being removed. A sudden disaster, such as a shipwreck or a reverse in war, at once attracts public attention, but constant and long-established evils such as tuberculosis and puerperal mortalities are more difficult to bring into public notice, though the total loss of most valuable lives be infinitely greater.

The opposition of a large number of the medical profession demands most careful consideration, but it is, I think, on the wane, as practitioners come to see that something must be done. The cry that midwives should be ended, not mended, and that every woman should be compelled to call in a fully qualified medical attendant is absurd and impossible, and the methods adopted against those who are endeavouring to improve the education of midwives have only brought discredit upon their authors. In Dr. Champney's address, already referred to, he said "some men sometimes waked up and found themselves famous," so the London Obstetrical Society found themselves (nearly but not quite, and in a strictly professional sense) infamous. A similar charge of infamy in a professional sense was at the same time brought against myself and the Master of the Coombe Hospital, and for the same reasons, namely, that we had been guilty of doing what we were authorised by Royal Charter to do and what my predecessors had done with great benefit to the public for upwards of a century, examining and granting certificates to midwives and monthly nurses. And these gentlemen carried this matter so far as to humbly pray the General Medical Council to remove our names from the Register of Medical Practitioners. Yet there is behind this burlesque a wide and serious feeling that the State recognition of midwives would be detrimental to the interests of the medical profession and would create a new order of medical practitioners. This fear it would be folly to ignore.

It is due in the first place to experience; such a class, for it is destitute of order, does exist, and does much harm. It has existed from all time, and only comparatively recently have medical practitioners invaded its domain, yet at the present time a large and increasing number of women seek the aid of medical practitioners, and this is because they have come to appreciate the value of such assistance, and I think what Virchow has recently said with regard to quacks applies to midwives, especially the untrained and ignorant "No penal law would succeed in driving those who seek aid from *midwives* to regular practitioners. This can be hoped for from better education and greater enlightenment of the masses." Since, then, this class does exist it is idle to talk of its creation, and it would be better were all to endeavour to improve it and confine its sphere of action within safe bounds than to offer an unbending resistance to all measures of reform.

Another cause for this feeling of distrust on the part of medical men is the definition of a midwife as a person who is to attend natural labours without the aid of a medical practitioner. In England you make a sharp distinction between midwives and monthly nurses. The former undergo a longer training and severer examination, and naturally regard themselves as superior to the latter. This, I think, is unfortunate, as the midwife might consider it as degrading herself to the condition of a

monthly nurse were she to seek the aid of a medical man, and that this is not a merely theoretical objection I can prove from the experience of a friend who practices in the south of England, who was sent for by a midwife to a case of placenta prævia, but no sooner had he arrived than she immediately departed, leaving him to face a very serious situation alone and unassisted. This distinction is not only injurious, but is artificial, and impossible to carry out in practice. Should a midwife meet with a complication, as in the case to which I have alluded, she should not only send for assistance, but she should remain and assist as a nurse. A monthly nurse, on the other hand, may not be able to secure the presence of the medical attendant at the time of the birth, and she then becomes a midwife, and should have been trained as such. In Ireland we make no such distinction, and midwives are generally ready to call in medical assistance. That this is a matter of importance has been proved by the agitation for the registration of obstetric nurses instead of midwives. Personally I can see no objection to the protection of the name midwife, but I do see serious reasons for abandoning the definition that she is qualified to attend without a medical practitioner. It has been urged that it is impossible to define natural labour. This may be so, but there is no practical difficulty in defining the conditions under which assistance is to be obtained. Anyone who has had the management of an extern maternity attended by medical students or midwives has had to overcome this difficulty, and has found that a few printed rules with salutary warnings as to punishment to be inflicted in case of neglect is all that is required. In the Rotunda Hospital the student is warned that if he fails to comply with the rules, and especially if he fails to send for assistance under certain well-defined circumstances he will be liable to expulsion, and his certificate withheld. In the case of a midwife, the fear of having her name removed from the *Register* would, I believe, insure her sending for assistance under similar circumstances. In the reports of the Rotunda Hospital there are lamentable examples of cases sent into hospital too late to save life, but in my experience such neglect was the result rather of ignorance than malice, and I believe that many untrained midwives fail to send for assistance because they are unable to recognise the necessity for it. Education should precede registration, but under existing circumstances I fear we shall have to use registration as an inducement to improved education.

Now as regards our attitude in Ireland, we are strongly opposed to any measure for protecting the appellation "midwife" from which we are excluded. We have for many years educated a large number of midwives, many of whom practise in this country, and we believe that if these women were obliged to come over here to be examined and educated, the expense of travelling and living would be so great as to deter the majority from coming to us, we therefore consider it unreasonable that you should expect us to burn our own fingers in pulling chestnuts out of the fire for you. Whatever our private opinions may be, like yourselves we are unanimous in opposing any measure which we consider will injure our Midwifery School, but why should we be excluded? Do we not suffer from bad midwives just as you do? If English mothers require protection, do not Irish just as much? But as a mere matter of policy I cannot understand why those who are anxious to pass such a measure should array against it the entire strength of the Irish Parliamentary representation.

NOTE ON A CASE OF LOOSE BODY IN THE KNEE-JOINT.

By R. GLASGOW PATTESON, B.Ch., Univ. Dub.,
F.R.C.S.I.,

Surgeon to the Meath Hospital and Co. Dublin Infirmary.

THE question of the origin of "foreign," or more properly called "loose," bodies in the joints, especially the knee, is involved in so much uncertainty owing to the numerous conditions which may give rise to them, that any case bearing on a phase of their pathology is worthy of short notice.

James G., æt. 45, a carpenter by trade, came to the out-patient department of the Meath Hospital in the beginning of October, 1898. He complained of "something being loose" in his left knee, and having caused the joint to "lock," which being intensely painful at the time, had been followed by a swelling lasting for several days and preventing him from following his usual occupation. When he presented himself for examination, the synovitis had almost subsided, but no abnormal body could be felt. He stated that he was at times able to shoot the loose body out to the internal synovial pouch close to the ligamentum patellæ, and was accordingly directed to come back to the hospital as soon as either he could locate the body, or locking of the joint occurred. About a week later he returned with a fresh attack of synovitis due to the nipping of the body between the articular cartilages, and was seen by Dr. Lennon who, recognising the cause of the condition, transferred the case to me. On admission he gave the following history: For the preceding six or seven months he had suffered from time to time from vague pains in his left knee which he regarded as rheumatic, and to which he paid little attention, as they never lasted more than a few days, and never interfered with his usual occupation. It was not until about five weeks before the date of his admission that he first became aware of the association of these recurring attacks of pain with the presence of something movable in his knee-joint; and it was only when the nipping of the body in the joint had led to synovitis that he thought "something had gone wrong," and came to look for treatment. Though stating vaguely that he had always been rheumatic, there was no history of any definite attack, and the only corroborative evidence seemed to be the flitting pains which he had noticed for some months previously. There was now a considerable amount of synovitis present; but after a few days' rest and treatment in hospital the effusion disappeared, the pain departed, but no coaxing by any form of passive movement could lure the loose body from its hiding-place. He was accordingly sent home, with instructions to return at once if the body became displaced, and to avoid as far as possible all movements which might tend to drive it back again into the deeper recesses of the joint.

On October 19th, five weeks after the first sudden onset, he came up to hospital immediately after a severe attack of locking of the joint attended with the most intense agony. When the resulting effusion had subsided under treatment, a matter of a few days, the body was found lying in the position it usually assumed on coming to the surface, viz., in the inner side of the joint resting between the internal condyle of the femur, and the inner articular margin of the tibia, and directly below the anterior border of the internal lateral ligament. The limb was placed on a posterior splint and the greatest quiet enjoined. The parts were gently but thoroughly cleansed, and the surface kept for 24 hours wrapped up in a compress of glycerine and corrosive sublimate (300—1). On the following day I cut down on the loose body, fixing it firmly between the left thumb and forefinger. No attempt was made to transfix it, as my

experience is altogether opposed to such a course in the case of "free" bodies. As soon as the ill-defined border of the lateral ligament and the capsule were fully divided, the body jumped up into the superficial incision. Practically no effusion into the joint followed the operation. The sutures, of silk-worm gut, were removed on the fifth day, passive motion was begun, and at the end of a week the patient was allowed up. A certain amount of stiffness remained in the joint for some weeks, but this gradually passed away, and since then the patient has had no return of his previous troublesome symptoms.

The body when examined with the naked eye after removal appeared to consist in about equal proportions of bone and cartilage. The bony part was pyramidal-shaped, surmounted by a semi-lune of cartilage at the base which overlapped somewhat the margin of the bone. The exposed portion of the bone bore distinct traces of "eburnation," the polishing of the surface being in places very evident. The point of chief interest, however, was the original seat from which the body had developed, and the cause of its growth.

In a paper published in the *Journal of Anatomy and Physiology*, vol. xxiv., April, 1890, I discussed fully the pathology of these loose bodies in joints, directing special attention to the observations and experiments of two French observers, MM. Poulet and Vaillard, who showed conclusively how large a proportion of bodies containing bone and cartilage were derived from the outgrowths which occur in chronic rheumatic arthritis, and often affect only a single joint, and not infrequently in comparatively young individuals. These occur about the margin of the articular cartilage, and often show traces of a fibrous investment, which is continuous on one side with the periosteum and on the other with the reflection of the synovial membrane. The body was handed to Professor O'Sullivan, who kindly made a detailed examination of it. It consisted of cancellous bone and hyaline cartilage, but the latter did not show any actively proliferating zone of cells, nor was the true fibrillar splitting of the matrix, seen in chronic rheumatic outgrowths, present. The microscopic appearances were, therefore, negative; but taking into account the absence of any traumatic cause, the previous occurrence from time to time of rheumatic pains, and the sudden separation of the body by natural causes apart from injury, it seems probable that in lieu of any other plausible causation, we had to deal with another instance of these curious "wandering osteophytes."

UTERINE MYOMA ASSOCIATED WITH TEMPORARY GLYCOSURIA AND UMBILICAL HERNIA; SUBPERITONEAL HYSTERECTOMY AND RADICAL CURE OF HERNIA; RECOVERY. (a)

By ARTHUR E. GILES, M.D., B.Sc.Lond.,
F.R.C.S.Ed., M.R.C.P.Lond.,

Assistant Surgeon, Chelsea Hospital for Women; Gynaecologist to the Tottenham Hospital.

In October, 1899, I saw Mrs. V. in consultation with Dr. A. S. Gubb, who, in examining an umbilical hernia discovered a large uterine fibroid, reaching to within two fingers' breadth of the umbilicus. Her principal symptoms were menorrhagia and frequency of micturition. She was *æt* 48, and had had one child, now *æt* 12. Menstruation had been increasing in quantity for some years, and had been increasingly abundant during the last 18 months, leaving her hardly ever free.

(a) Specimen shown at meeting of British Gynaecological Society, February 8th, 1900.

Examination confirmed the diagnosis of uterine myoma; the tumour was the size of a pregnant uterus at the fourth month, and nearly filled up the inlet of the pelvis. In view of the present symptoms, the presence of the umbilical hernia, and the risk of impaction of the tumour in the pelvis, I concurred in the view that hysterectomy was indicated, this operation allowing me to procure the radical cure of the hernia as well. She was placed in a home, and on examination of the urine, Dr. Gubb found that sugar was present, amounting to 5 per cent. She had neither thirst nor polyuria, and the glycosuria was quite recent, since a short time previously Dr. Gubb had found the urine normal. Moreover, there was no wasting, but, on the contrary, the patient was a stout, florid woman with very fat abdominal walls. We therefore decided that the sugar did not mean diabetes, but was probably of functional origin, due to the nervous apprehension of the operation manifested by the patient. Under the circumstances I did not regard the glycosuria as a contra-indication to operation. On Nov. 3rd I performed a sub-peritoneal hysterectomy. The incision was carried up above the umbilical hernia, which was first dealt with by excision of the sac, and the uterus was then removed in the usual way. The operation was rendered rather difficult by the thickness of the abdominal walls, but otherwise presented no special features. The ovary and tube were left on one side. Recovery was uneventful, and the patient left the home well, three weeks after the operation. Sugar persisted in the urine for a week after operation, and then disappeared. It has not reappeared since.

I do not know of an instance in which a uterine myoma has been recorded as complicated with glycosuria; the association of glycosuria with ovarian tumours has been noted, and I may refer to an interesting case reported by Halliday Croom (a). In that case the patient presented other symptoms of diabetes, and the condition was regarded by Halliday Croom as being due directly to the presence of the tumour, by pressure, disturbing either the pancreatic functions or the hepatic circulation. I do not think that in my case the glycosuria was due in any way to the tumour, for two reasons, first, because the sugar in the urine was of quite recent occurrence; secondly, because in that case one would expect glycosuria to be more frequently found with large myomata.

This case shows that glycosuria is in itself no contra-indication even to so grave an operation as hysterectomy. Wallace has recently shown (b) that it is in many cases a positive indication for operation in cases of gangrene. He regards the glycosuria as due in these cases to a septic process; and believes that many cases of chronic suppuration are on the verge of glycosuria. If these various views be correct, then, in addition to the usually accepted causes for glycosuria (pancreatic or hepatic disturbances) we may put down pressure of tumours (Halliday Croom), septic absorption (Wallace), and functional nerve disturbance, as in my case.

Clinical Records.

CASE OF A VERY DISTENDED PYO-SALPINX OF THE RIGHT SIDE, THE OPPOSITE TUBE DISTENDED AND THICKENED, UTERUS REMOVED BY SUB-PERITONEAL METHOD. RECOVERY. (c)

By F. A. PURCELL, M.D., M.Ch.,

Surgeon to the Cancer Hospital.

E. C., from Newport, Mon., *æt* 36, married, was

(a) Halliday Croom, *Brit. Gyn. Jour.*, Vol. 11, p. 476.

(b) Wallace, *Lancet*, December 23rd, 1899.

(c) Read before the British Gynaecological Society, Feb. 8th, 1900.

admitted to the Cancer Hospital August 28th, 1899, complaining of a lump in lower abdomen, causing great pain. Not been well for thirteen years. Mother of two children. Her mother died of cancer.

About thirteen years ago she had a yellowish discharge from the vagina, accompanied by great pain in the womb, for which she sought treatment at Winchester Hospital for eight weeks. She was told there the womb was prolapsed and was given an instrument to wear. Three years later the same thing happened and she returned to the hospital for seven weeks; she was unable to wear the instrument. Seven years ago the same occurred in India; again three years ago, and every winter since. She now complains of great pain and swelling in the pelvic region, menses irregular in time and quantity during last six months, as occurred during previous attacks; frequency and difficulty in micturition; urine, sp. gr. 1014 acid, no albumen, tongue furred, dyspeptic; bowels constipated, defecation painful, except with liquid stools, abdomen not distended, muscles held rigid, tender on pressure.

Per Vaginam.—Tumour felt in pelvis, pushing cervix to anterior vaginal wall, it cannot be isolated from uterus. Per rectum, the tumour is felt impacted in Douglas's pouch and undoubtedly cystic, on consultation laparotomy was decided upon.

Operation, September 27th, 1899.—Having been duly prepared she was anaesthetised by means of gas and ether, the abdomen was opened between umbilicus and pubes to the side of the linea alba, through the fibres of the rectus muscle, patient was then raised into the Trendelenburg position, a large fluctuating tumour found occupying the right side of the pelvis, being about the size of a fetal head of six months' gestation, firmly agglutinated to side of uterus, old standing adhesions with thick organised lymph bound down the caecum, the uterus normal size pressed over to the left; the left tube lay much enlarged and thickened, bound down with organised lymph. The caecum was freed, and in tracing the appendix it was found bound down and stretching across Douglas's pouch to the right, three inches long and attenuated; this was freed and removed. An attempt was made to enucleate the tumour, but it was found impossible to separate it from the uterus; in the manipulation the cyst burst, and gave exit to a large quantity of thick pale pus; some escaped into the abdominal cavity. Total removal of the uterus was then decided upon and carried out by the subperitoneal method; an iodoform gauze drain was passed down the canal of the cervix and os into the vagina; the sigmoid flexure rose up behind the uterus, hard and tense and resembled a fibroid, but was recognised as intestine; the stump of the cervix was not sutured together, no blood was lost; the pelvic peritoneum was carefully stitched across with catgut. The abdomen was then freely flushed out with warm saline fluid, some gallons used, to wash out the pus that had escaped. No drain was inserted beyond the gauze already mentioned; a single row of silkworm gut sutures was used to unite the abdominal wall. Patient made a good recovery, and left hospital much improved in every way, looking stouter than when admitted.

The specimen presents a large sac now much contracted from the spirit solution, so that its size *in situ* can hardly be surmised. After removal it was found to be impossible to free it from the side of the uterus. The opposite tube is to be seen enlarged and thickened; the ovaries were allowed to remain. The question I should much wish answered is, was it feasible to enucleate the sac? And was I justified in removing the uterus?

CASE OF CHRONIC TOTAL INVERSION OF THE UTERUS. (a)

By F. WINSON RAMSAY, M.D., F.R.C.S. Ed.,
Bournemouth.

L. S., married, æt. 48, admitted to R. V. H., December 28th, 1898, suffering from incontinence of urine and chronic uterine trouble.

(a) Read before the British Gynecological Society, Feb. 8th, 1900.

History.—Always well and healthy, had several children, last child born fourteen years ago; had normal labour, but the doctor had to peel off the placenta. Three days after labour, had castor oil, and while on the bed pan, the uterus came out into the pan. Doctor arrived within three-quarters of an hour, pushed it back into vagina, and kept it there with a pad and bandage; no excessive hæmorrhage. Seemed to have a swelling inside vagina, which gradually felt better, was able to get about and do some work, but from that day has always had a little bloody discharge. About twelve months after consulted a doctor, who introduced a Zwanck's pessary, which gave some relief; patient took it out once a week for cleaning. In March, 1898, a larger pessary was given her, and as she still complained of pain in back and bearing down, she was told not to take it out so often. In May, 1898, patient noticed that the water was always running away from her.

In September, 1898, patient was unable to remove the pessary. The doctor told her it was covered with a deposit of gravel, and it had to be broken in pieces and removed under chloroform. After removal of the pessary water ran away more than ever.

Examination.—Revealed at once a completely inverted uterus, not much larger than a normal uterus, and covered with stinking slime and phosphates; the base of the bladder was completely gone, exposing the fundus, and the edges were composed of a ring of dense cicatricial tissue. After rendering as aseptic as possible, uterus was removed with a pair of scissors on January 3rd, 1899. Operations for closing fistula February 18th, March 22nd, April 11th, June 13th, July 12th, August 15th. After operation required to empty bladder about every half hour. Now quite well, does all her work, can go easily three hours every day, and never gets up at night. Expect further improvement still.

Transactions of Societies.

BRITISH GYNÆCOLOGICAL SOCIETY.
MEETING HELD FEBRUARY 8TH, 1900.

W. J. SMYLY, M.D., President, in the Chair.

SPECIMENS.

DR. ARTHUR GILES showed a specimen of uterine myoma removed by subperitoneal hysterectomy from a patient with glycosuria, the notes of which will be found under "Original Communications."

DR. WILLIAM TRAVERS observed that the glycosuria in this case was probably functional. He would like to ask what were the symptoms that called for the operation of hysterectomy, apart from the presence of the glycosuria, since apparently the latter was in no way due to the tumour. At the present time, when the question of operation for fibroids was being largely discussed in the medical press, it was very important to know the reason for operation in each case.

DR. MACNAUGHTON-JONES said that though a relationship between ovarian tumour and diabetes or glycosuria had frequently been noticed, it was not so with regard to myoma of the uterus. Post-operative glycosuria was not uncommon, and after ovariectomy its disappearance had been explained by the emptying of the large veins and a consequent anæmia of the liver, as interference by pressure with either the portal or the hepatic artery might cause it. In the case of the uterus it was different. In ovarian tumour there might be pressure on the pancreas, but these causes were not present in the case of a myoma unless it were of an exceptionally large size. In Dr. Giles' case he should regard the glycosuria either as a coincidence or as a result of a reflex nerve irritation, and that there was here no relationship as of cause or effect.

DR. HEYWOOD SMITH agreed with Dr. Giles that the glycosuria in this case was probably due to impression on the patient's mind; although it was to be remembered that pressure effects might result from even a relatively small tumour.

Dr. W. H. BOURKE asked whether in this case the glycosuria was quantitatively estimated?

Prof. W. JAPP SINCLAIR (Manchester) observed that there were many points in this case in which more facts were desirable; for example, the amount of urine passed during the time that glycosuria was present; the relation of glycosuria to meals, and the time of day, &c. On what grounds did Dr. Giles say that the case was not one of diabetes? In his experience, when sugar had been constantly present in the urine, the patient had always died.

Dr. INGLIS PARSONS said that it was a matter of some importance whether the patient was very stout or not. There was a stout type of women who had glycosuria, not because of the existence of diabetes, but because of the dietetic habits. In a case of true diabetes, the condition would be a bar to operation. He judged that Dr. Giles' patient came under the first category.

Dr. GILES, in replying, said that the case was not one of diabetes, since there was no thirst, polyuria, or wasting. He regarded the glycosuria as of purely nervous origin, and as in no way related to the presence of the tumour. His main purpose in reporting the case was to show that glycosuria was in itself no contra-indication for operation. In reply to Dr. Travers, the grounds for interference in this case were menorrhagia and pressure symptoms. As would be seen from the specimen, the tumour was just about large enough to fill up the pelvic inlet.

Dr. F. A. PURCELL showed a specimen of large pyosalpinx, together with uterus, removed by subperitoneal hysterectomy. Full notes thereof will be found under the head "Clinical Records."

Prof. JAPP SINCLAIR remarked that if it was justifiable in this case to leave the ovaries, they must have been healthy; and if the ovaries were healthy, whatever the condition of the tubes, the best operation would have been vaginal incision and drainage.

Mr. FURNEAUX JORDAN considered that the treatment to be adopted depended largely on the condition of the tube of the other side, for unless there was much disease of the other tube, he did not think that they would be justified in removing the uterus. When the adhesions were so great that they could not be separated, it was better to incise through the vagina and drain. In such cases there was always a history of repeated attacks of peritonitis, and this would lead to a correct diagnosis. He did not see how it could be necessary to remove the uterus. It was all very well to say that the uterus was no good; but even if the woman could neither bear children nor menstruate, he still saw no advantage in removing the uterus as long as drainage was possible. He would make an exception in a case where the sac burst, and it could not be removed without removing the uterus. In any case he thought that the vaginal route was the best.

Dr. MACNAUGHTON-JONES said that as Professor Japp Sinclair and Mr. Furneaux Jordan had spoken against removal of the uterus in cases of extensive pyosalpinx, it might be well to hear a word on the opposite side of the question. At the International Congresses it was incontrovertible that the majority of continental and American authorities had decided in favour of salpingo-hysterectomy in cases of pelvic suppuration and double pyosalpinx, and the same might be said of the International Gynaecological Congresses. In the route by posterior colpotomy the complete removal of such suppurative adnexa was often most difficult, if not impossible. Salpingo-hysterectomy in such cases, without materially increasing the risk, facilitated the complete removal of the diseased ovaries and tubes. In abdominal coeliotomy, which in such cases he himself would prefer, he believed also that salpingo-hysterectomy was the right operation to perform. While the disadvantages of leaving the uterus were apparent, the advantages were most doubtful, for it should be remembered that in these cases the uterus was frequently the starting point of the disease, there had been old endometritis, and in a large proportion of the cases, gonorrhoea was the source of the mischief. He failed, therefore, to see the gain to the woman of leaving an unhealthy and useless organ.

Dr. INGLIS PARSONS thought that Mr. Furneaux Jordan spoke to the point when he said that if one side was healthy the uterus should not be removed. He preferred the abdominal route for dealing with pyosalpinx; at the Chelsea Hospital for Women they had found that in nearly all cases the contents of a pyosalpinx were sterile; and if a little pus escaped during the operation, it did not much matter. Certainly the possibility of this accident was no contraindication to operating through the abdomen.

The PRESIDENT said that his view was in favour of removing the uterus, because when both sides were so much diseased as in this case the uterus was also diseased; and if it were left, the patient was not cured. The pus in the tubes was not always sterile; he had found cases where it was otherwise.

Dr. PURCELL, in reply, said that if he had attacked this case by the vagina he would have got into great difficulties owing to the bowel adhesions; and the case would probably have ended fatally. The balance of opinion in the Society seemed to be that in the case of double tubal disease with uterine adhesions it was safer to remove the uterus as well. Time would show whether it was judicious to leave the ovaries in this case.

Dr. PURCELL also showed a card specimen of a fibromyoma of extraordinary shape, springing from the uterine fundus. It was a sausage-shaped mass, 10 inches long and of the thickness of a man's wrist; in its fresh state it resembled a stunted cactus plant. It was removed by subperitoneal hysterectomy from a nulliparous patient, *et. 40*, on January 10th, 1900. Convalescence was afebrile and terminated in recovery.

Dr. F. W. RAMSAY (Bournemouth) read the notes of a case of chronic total inversion of the uterus, which will be found under the heading of "Clinical Records."

In the discussion that followed, Dr. CLEMENT GODSON thought that there was no doubt that Dr. Ramsay's treatment of this case had been good throughout. It would have been useless to try to restore the uterus, in view of the condition of the bladder. Had there not been a vesico-vaginal fistula it might have been possible to reduce the inversion by means of Aveling's repositor, since this could be effected when an inversion had existed for many years. He had on several occasions restored such a uterus. Zwanck's pessary should never be allowed to remain *in situ* for any length of time, but should be removed every night and replaced in the morning. Before the introduction of colporrhaphy he had often used this pessary at St. Bartholomew's, with good results.

Dr. MACNAUGHTON-JONES said that Dr. Ramsay deserved their warmest congratulations on the issue of a class of case which was one of the most difficult to effect a cure in, and for the originality of the idea of closing so large a vesical opening by transplantation of the vagina and implantation of the uterus. The first who so utilised the uterus by the supra-pubic method was Dittel. Martin had formed a floor for the bladder with the vaginal tissue, and Howard Kelly's operation was very much the same as that mentioned by Dr. Ramsay. A Zwanck's pessary, unless carefully disinfected from time to time, and regularly removed for cleansing, was simply a mechanical contrivance for the incubation of septic filth in the vagina.

Prof. W. JAPP SINCLAIR related a case in which he found a vesico-vaginal fistula in a patient who gave a history of forceps delivery. There was a considerable loss of tissue; and it seemed to him that the only thing to do was to turn the uterus itself into the bladder. This he did, and the patient thereafter went on menstruating through the bladder without any inconvenience. This showed that the surface of the uterus as well as that of the vagina, need cause no bad results when turned into the bladder.

Dr. JAMES OLIVER thought it hardly possible that a woman with complete inversion of the uterus could have worn a Zwanck's pessary; but it was difficult to say when the inversion could have occurred in this case, but it might have happened when the pessary was removed. He had in one case removed an inverted uterus from a patient, *et. 55*, where it was the result of a small myoma.

Dr. RAMSAY, in reply, said that for the history of the case he had to depend entirely on the patient's statements; his own view was that the inversion had been present all the time, but he had some doubts on the subject, because she had seen several doctors who apparently did not diagnose that she had an inversion of the uterus.

The President, Dr. W. J. SMYLY (Dublin), then delivered his Inaugural Address, which will be found in another column.

After its delivery a vote of thanks to the President was proposed by the retiring President, who, in the course of his remarks referred to the midwives' question, which was again before the profession. The Gynæcological Society had, he said, always approached it in a fair and liberal manner. They did not object to the enforcement of a systematic course of education for midwives, or, as he would prefer them to be called, monthly nurses, for he did not believe in the necessity, as others did, for the perpetuation of the term "midwife" as applied to unqualified women. Every medical practitioner was by law a midwife, and, since such qualification had become an essential part of a registerable diploma, without which the State permitted no one to practice medicine as a registered practitioner, there was the serious risk of confusion in the public mind as between two classes of midwifery practitioners. They had to consider the question from a tri-partite point of view, one part of which could not be separated from the other two, namely, the interests of the public, the profession, and of the midwives themselves. He protested against any step which would dim the prestige or sully the traditions associated with the Obstetric art, and he appealed to the President, looking back over the long and illustrious roll of Obstetricians associated from the time of Ould, with his own school of midwifery, to say if it would not be unwise that with their eyes open they should take any step which might in the least degree be retrogressive and impair those traditions and that prestige. The Gynæcological Society had last year approached the General Medical Council by a memorial on the subject and with regard to the present Bill, and had received from the General Medical Council a reply to the effect that the lines of that memorial were those upon which the Council had always proceeded, and which had actuated the steps which it had taken. Thus it was evident that the position of this Society was practically in accordance with the views of the General Medical Council. He congratulated the President on his position in the Chair of the British Gynæcological Society, which was proud of him as its President, representing as he did perhaps the most famous Obstetric School in the world—the Rotunda Hospital of Dublin—of which he was a Past Master.

Dr. C. H. F. ROUTH, in seconding the vote of thanks contrasted the teaching of gynæcology to-day with what obtained when he was a student. He admired the liberal and tolerant manner in which the President had discussed the midwives question in the second part of his address. His own view of the matter was that they must have midwives, but that they should be put into their proper places.

The vote of thanks was carried by acclamation.

The PRESIDENT, in acknowledging it, said that one reason which induced him to bring forward the midwives' question was that in Ireland they had always refused to give any opinion on a Bill from which they were to be excluded. This was the first time that he had had the opportunity of speaking not simply as an Irishman, but as a Britisher.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF SURGERY.

MEETING HELD FRIDAY, JANUARY 19TH, 1900.

The President, Mr. R. L. SWAN, F.R.C.S.I., in the Chair.

FIRST CLINICAL EVENING.

EPITHELIOMA OF THE EPIGLOTTIS AND LARYNX.

MR. H. GRAY CROLY exhibited a male patient, æt. 42,

with a growth on the epiglottis. No history of syphilis. The patient became emaciated and suffered from considerable dyspnoea, and tracheotomy was performed a month after admission under chloroform.

Professor BENNETT discussed the propriety of any further proceeding. To remove a portion of the larynx without removing the tract of lymphatics reaching to the junction of the subclavian and internal jugular veins would be a grave matter.

Mr. CROLY, in reply, said the glandular enlargement was, to his mind, proof positive that the disease was not benign. His present inclination was to let sleeping dogs lie.

GOITRE REMOVED BY THE AID OF LOCAL ANÆSTHESIA BY COCAINE.

Mr. JOHN LENTAIGNE exhibited a patient from whom he had removed the greater portion of a very large goitre on September 4th, 1899, entirely under local anæsthesia by cocaine. The patient, J. P., æt. 20, was admitted on August 29th, suffering from a huge goitre, which consisted of three lobes, a very large right lobe, a large middle lobe, and a comparatively small left lobe, causing severe and constant dyspnoea aggravated by exertion, and it was on account of this dyspnoea that Mr. Lentaigne felt himself bound to attempt removal of the growth by means of local anæsthesia, instead of employing ether or chloroform, either of which would, in such a case, add considerably to the danger of the operation. Very little blood was lost as the vessels were tied before being cut. The goitre proved to be of the colloid variety, and the left lobe, which had been left, had shrunk since the operation to such an extent as to be now barely noticeable, and the patient was in excellent health and condition. The incision employed was the collar incision recommended by Professor Kocher.

After some remarks by Mr. CROLY,

Dr. KNOTT asked what was the total amount of cocaine used, and what time elapsed from the application to the commencement of the operation?

Mr. HEUSTON asked whether the dyspnoea was a pressure dyspnoea or a nerve dyspnoea?

Mr. LENTAIGNE, in reply, said there was very distinct pressure from behind. The cocaine was used hypodermically, and was injected along the line where the incision was subsequently made. From time to time a little cocaine was dabbed on the tissues. The total amount of cocaine used was certainly not more than $\frac{1}{2}$ gr. A 1 per cent. solution made with sterilised water, and which also contained 2½ per cent. of carbolic acid, was used.

FOREIGN BODY IN THE KNEE-JOINT.

Mr. R. L. SWAN showed a young man, æt. 22, from whose knee, two years ago, he had removed a loose cartilage in the ordinary manner at the inner side. Soon afterwards he began to complain of symptoms indicating the presence of another similar body in the joint. Nothing, however, could by the most careful examination be felt. Mr. Swan waited for some time in the hope that the body would become detached, but the constant occurrence of locking of the joint, followed by synovitis, had the effect of rendering the limb useless. A skiagraph showed the outline of a foreign body in the joint. A lateral incision at the outer side was made, but this proved inefficient. Accordingly a transverse section of the patella was made, and the body was found attached by a strong fibrous envelope to the intercondylar notch. The patient exhibited a perfect joint.

Mr. MILES asked whether Mr. Swan had drained the joint?

Mr. CROLY suggested Mr. Swan might have performed the operation by pushing the patella to one side and getting at the notch between the condyles without complicating the case.

Mr. LENTAIGNE suggested the locking of the joint and the sickening pain were due to sudden and violent strain on the ligaments.

Mr. SWAN, in reply, said he would not have ventured to operate if he had not the skiagram before him. He used two silver wire sutures for the patella. He did not drain the joint beyond the necessary cleansing in the progress of the operation.

LIGATION OF SUBCLAVIAN ARTERY FOR AXILLARY ANEURYSM.

Mr. FRANCIS HEUSTON brought forward a man on whom he had ligatured the left subclavian artery, in its third stage, for traumatic subclavio-axillary aneurysm, four years since. At the time of the operation he was *æt.* 50, and had been 20 years in the army. He was admitted to the Adelaide Hospital in February, 1896, suffering from severe pain in his shoulder, left arm, and back, which was then continuous, although it had been for some time at first intermittent. The superficial veins of the left arm were tortuous, the arm being also swollen and oedematous. The clavicle was raised by a tumour occupying the supra and infra-clavicular regions, presenting a well-marked bruit, distensible pulsation, and thrill. There was well-marked difference of the pulse in the right and left arms. The artery was ligated by catgut applied close to the outer side of the scalenus anticus muscle, the patient leaving hospital 23 days after operation, and resumed his ordinary occupation, which he has filled since without any return of symptoms.

Mr. MYLES asked whether Mr. Heuston drew the ligature sufficiently tight to break the inner and middle coats, or to destroy the circulation?

Mr. CROLY asked if Mr. Heuston had any difficulty with the lower cord of the brachial plexus or with the external jugular vein. Why did he select catgut in preference to ligatures such as ox peritoneum, which do not become absorbed too rapidly? Was the subclavian vein seen?

Mr. LENTAIGNE asked why Mr. Heuston called it a traumatic aneurysm, the blow having been received two years before its appearance?

Mr. HEUSTON, in reply, said he was able to feel the artery at the cope of the sterno-mastoid. He tied the ligature with sufficient force to rupture the inner and middle coats. The lower cord of the brachial plexus gave no trouble, and he was able to push the external jugular vein out of his way. He used catgut because it was the first aseptic absorbable material he could get. He called the aneurysm traumatic, from the fact that the man had got an injury, although it had not come on for some time, and what he found at the operation proved that he was right.

LIGATION OF POPLITEAL ARTERY FOR ANEURYSM.

Mr. ARTHUR CHANCE exhibited J. B., *æt.* 33, and married. He had had syphilis. His duties entailed the lifting of very heavy weights. Early in May last he noticed a dull pain at the back of his right knee, where a small pulsating tumour formed. On admission he was found to have in his right popliteal space a tumour about the size of a Tangerine orange, which showed all the classical signs of aneurysm. The right foot was much swollen and oedematous. The artery was exposed at its upper part by an incision parallel to the adductor magnus, tied with silk, and the wound healed by first intention. It is now six months since he has returned to his duties in the railway works, and there is no sign of trouble in the aneurysm.

Mr. CROLY asked if Mr. Chance had tried pressure before tying the artery?

Mr. HEUSTON asked if, previous to the ligation, any treatment was employed, and if so, what was its nature, and for how long was it used?

Mr. CHANCE, in reply, said he did not try pressure. One of the drawbacks of pressure in these cases was that it established a collateral circulation which often interfered with the ligature. He tied the popliteal artery—first, because the man's foot was very oedematous, and it was necessary to choose the method which would best establish the collateral circulation; secondly, because the man was young; and thirdly, because he was occupied in exceptionally heavy work. There was a considerable distance between the aneurysm and the ligature.

The Section then adjourned.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

MEETING HELD WEDNESDAY, FEBRUARY 7TH, 1900.

DR. DUNSMURE, Vice-President, in the Chair.

DR. ALEXANDER BRUCE exhibited a man, *æt.* 33, suffering from disseminated sclerosis of two years' duration, who showed adductor clonus. All the deep reflexes were greatly exaggerated. When the patient was seated with the toes resting on the ground adductor clonus ensued, and continued for about ten minutes. Many cases of insular sclerosis had come under Dr. Bruce's care of late years; the increased number was probably to be ascribed to the epidemics of influenza.

Mr. C. W. CATHCART showed a boy, *æt.* 15, whose cæcum had been removed for tuberculous ulceration and contraction. The boy had suffered from chronic obstruction for six months, and on opening the abdomen a mass was found at the ileo-cæcal valve, which was firmly adherent to the adjacent structures. This was excised and the ends of the bowel reunited by sutures. Since the operation, six weeks ago, the patient had gained over a stone in weight. The wall of the cæcum was much thickened, and the lumen contracted to about one-sixth of an inch.

Dr. NORMAN WALKER showed a girl, *æt.* 20, suffering from an ulcer of the forearm. The diagnosis was obscure, but lay between syphilis and tubercle; the majority of the members were inclined to regard it as the latter.

Mr. F. M. CAIRD showed specimens illustrative of syphilitic necrosis. (1) Sequestrum from the upper jaw of a patient who had a hard chancre eight years before, and had been thoroughly treated abroad by inunction. (2) A large sequestrum from the upper jaw of a patient who contracted syphilis eleven years ago, and was treated in the ordinary way by mercury internally. (3) A sequestrum of the calvarium taken after death from a girl, *æt.* 20, the subject of congenital syphilis.

Mr. WALLACE showed a specimen of fracture of the lower end of the radius, with (probably) the rare forward displacement of the lower fragment.

Mr. COTTERILL showed a modification of the trephine. It was much simpler than that ordinarily in use, consisting of only two parts, which were readily separable for cleansing purposes.

Mr. C. W. CATHCART showed a method of keeping gauze dressing rolled up in balls like those in which ordinary twine is wound. The gauze could easily be cut off as required without risk of rendering the remainder septic.

Mr. CAIRD read a short note on a case of

LIGATION FOR FEMORAL ANEURYSM.

The patient was an old man, *æt.* 74, who had had a pulsating inguinal swelling for some months. In August last, the swelling increased greatly, and signs of rupture of the sac developed. When seen in October the thigh was enlarged, cold, and discoloured; there was no tibial pulse. The choice of operation lay between ligation of the external iliac and femoral artery, and the latter was decided on. As the patient refused to go into hospital, the operation had to be done, under most unfavourable surroundings, in his own house, yet, in spite of the fact that he suffered from delirium, retention of urine, and bronchitis, and utterly refused to stay in bed, he made a good recovery.

Mr. WALLACE read notes on

HEMATURIA DUE TO BILHARZIA HÆMATOBIA.

He described the geographical distribution of the disease, pointing out that in Egypt and South Africa hæmaturia was so common among boys and men as almost to pass unnoticed. In South Africa it was generally thought to be due to drinking impure water; in Egypt the parasite was believed to gain entrance by the urethra in bathing. Three cases—all young men from South Africa—had recently come under his notice. In the first case, a man, *æt.* 24, the hæmaturia had begun two months after he arrived in South Africa. Besides

the bleeding, priapism and seminal emissions were complained of—due probably to the irritation caused by the presence of the ova. The second case was a man, æt. 21, born in South Africa, who had been the subject of hæmaturia since his thirteenth year. He suffered from severe renal colic simulating that due to stone. He was examined by the cystoscope and skiagraphy with negative results, and the conclusion came to was that the colic was due to the passage of pellets of mucus. The third patient was a young man from Natal, whose only symptom was hæmaturia at the end of micturition. In such cases the ova should be sought for in the clots. The ova passed *per urethram* had terminal spines; in those passed by the rectum the spines were lateral. The bleeding usually ceased gradually after the patient left the infected district. Salol inwardly had seemed of use.

Dr. UNDERHILL had seen similar cases. In one—a young lady who suffered from severe colic—the administration of boric acid gave great relief.

Dr. IRELAND read a paper on the

INCREASE OF NERVOUS DISEASE AND INSANITY.

He alluded to a recent paper of Professor Erb, and pointed out that although modern life brought with it causes of additional nerve strain in the tendency to over-tasking at schools, in the greater demands made upon the learned professions by the advancement of knowledge, in the exciting character of many modern amusements, and in the increasing competition in every walk of life, yet the new conditions brought with them certain compensations. Men travelled more, and had more time for recreation and change of scene; their dwellings were more healthy, and the sanitary condition of both town and country was vastly improved. Drunkenness was undoubtedly less common, and the standard of living of the poorer classes was certainly better than thirty years ago. On the whole, the stress of life told most heavily on the middle classes. He wished that Professor Erb had brought forward direct evidence of the increase of nervous diseases, but it was most difficult to obtain trustworthy statistics on this point. He (Dr. Ireland) had addressed the following series of questions to a number of practitioners both in town and country:—1. Have you found that since you began to practise medicine there has been any increase in the relative frequency of diseases of the nervous system? 2. Have new forms come into prominence? 3. Have you observed any change in the type of old diseases? A good many replies to these circulars were received, the most valuable—as was to be expected—being from practitioners in the country. Of course many obvious fallacies must be remembered, but the general tenour of the answers was to the effect that the men who had practised for long in the same district and among the same class had seen no great increase in nervous disease. Practitioners in town, however, thought that a considerable increase in the less severe types—such as neurasthenia—was noticeable. Dr. Byrom Bramwell regarded disseminated sclerosis as much more common since influenza had become prevalent. The remainder of the paper was devoted to an elaborate statistical investigation of the frequency of severe nervous diseases in Scotland, and from this Dr. Ireland had come to the conclusion that organic nervous disease, suicide, and insanity were more prevalent in Scotland now than formerly, just as in the case of other countries.

The paper was discussed by Dr. T. S. CLOUSTON.

LIVERPOOL MEDICAL INSTITUTION.

MEETING HELD JANUARY 25TH, 1900.

Mr. EDGAR BROWNE, President, in the Chair.

Dr. T. R. BRADSHAW showed a man, æt 24, a boiler maker, with extreme atrophy of the right trapezius, biceps, and brachialis anticus. The wasting had come on gradually, and its distribution suggested the commencement of the facio-scapula-humeral form of idiopathic

muscular atrophy, but it was possible that it was due to overuse of the affected muscles.

Dr. MAX LOWENTHAL read notes of a case of "fibrinous bronchitis."

Dr. NATHAN RAW read a paper on the

PATHOLOGY AND TREATMENT OF PNEUMONIA,

based on an observation of 1,047 cases during a period of twelve years. The general death-rate of the whole of the cases was 23·4 per cent. During the last two-and-a-half years, 317 cases of pneumonia had been admitted into Mill Road Infirmary (including, of course, all forms of pneumonia, and those dying shortly after admission) with a total death-rate of 34 per cent. With regard to the pathology of the disease there could be no doubt it was caused by a specific micro-organism, the *diplococcus* of Frænkel, influenced to a very great extent by rapid changes in climate, and a low resisting power in the individual. This low resisting power he had noticed most frequently in the chronic alcoholic who rarely recovered from a bad attack of pneumonia. Dr. Raw reviewed at length the various forms of treatment, which had been used in the past, and were being employed at present, and gave it as his opinion that no specific form of treatment influenced the progress of the disease or in any way cut it short. He was of opinion that the treatment of the future would be antitoxic, the anti-pneumotoxins being either procured by removing serum from a patient who had just recovered from pneumonia or experimentally from immune animals.

Dr. WATERS spoke of the statistics of other hospitals, the mortality in pneumonia varied, and the percentage would differ according as complicated cases were included or not. Dr. Waters had tabulated all the cases occurring in his hospital practice to the number of 151 with a mortality of 7·28 per cent. He had no doubt of chill and exposure as an exciting cause. With reference to treatment, he thought many cases would do well without much active interference, and attached much importance to nursing, dieting, and the surroundings of the patient. He had never practised venesection. He attached great value to carbonate of ammonia, and in many cases gave varying quantities of alcohol. In certain adynamic cases he thought quinine was useful, and in extreme cases had seen good results from the inhalation of oxygen, and injection of strychnine with free use of stimulants. He was in favour of mild counter-irritation, but did not approve of blistering in the early stages.

Dr. CARTER thought that on clinical grounds one must recognise two different forms of pneumonia—(1) Simple and tending to recovery; (2) Septic and very dangerous. He noted the variation in intensity of the disease in different years, and thought that there was a general epidemic influence that gave undue intensity to the disorder, instancing small-pox in 1881 and influenza at the present time. Referring to treatment he believed that where the cardio-pulmonary mechanism was seriously disturbed by the sudden invasion, as evidenced by gasping, small pulse, ashy colour, orthopnea, &c., the abstraction of a few ounces of blood relieved, and favoured recovery. There was one stage where opium was useful, viz., where there was a sudden fall of 6–8 degs. of temperature at the period of crisis with the onset of active delirium, physically, except for this fall in temperature, the patient seemed the same, the same amount of exudation being present, but vitally he was different, and a good sleep, which then may safely be produced was most restorative. In all other conditions opium was injurious. In hyperpyrexia he had seen marked improvement by a single cold bath or the application of cold cloths.

Dr. GLYNN considered that the mortality from pneumonia had been higher in Liverpool in recent years than it was 20 years ago—that deaths now were not infrequent in young people, whereas Barthez had only met with 2 deaths in 212 cases of pneumonia in subjects under 16. The rate of mortality was also influenced by the length of time elapsing between the onset of the illness and the commencement of treatment. Gripalle's figures emphasised this statement. He found that the mortality among patients admitted to the hospital on the first and second days of disease was 1 in 15, on the fourth

day 1 in 8, and on the sixth day 1 in 4. The pneumococcus, often associated with other organisms, had been found in the sputum in all of his cases of pneumonia. He discussed the value of leucocytes as an aid to prognosis, and referred to the various theories advanced to explain the crisis. In treatment he often resorted to physical measures for reducing the temperature, to large doses of digitalis for procuring sleep, or hypodermic injection of atropine, and believed in the efficacy of salicylate of soda and ammonia.

Dr. BARR made some remarks, after which the discussion was adjourned until February 8th.

MEETING HELD FEBRUARY 8TH, 1900.

The President, Mr. EDGAR BROWNE, F.R.C.S.,
in the Chair.

Mr. WM. JONES, the resident Librarian having been twenty-one years in the service of the Medical Institution, the members wishing to mark their appreciation of his services had collected a sum of £193 12s. 9d. (£95 6s. being collected by Dr. Kentoul, and £98 6s. 9d. by a sub-committee of the Medical Institution), and the President presented to Mr. Jones a cheque for that sum. Mr. Jones thanked the members, introducing some interesting reminiscences in his remarks.

THE TUBERCULOSIS CRUSADE.

Dr. NATHAN RAW proposed: "That it is desirable that a local branch should be established in Liverpool, in connection with the National Association for the Prevention of Consumption, and other forms of tuberculosis."

Dr. CARTER seconded, and the motion was carried *nem. con.*

Dr. HOPE said that Liverpool had through its City Council, Medical Institution, and Boards of Guardians, and the munificence of private individuals, taken active measures in regard to tuberculosis, but no branch of the National Association had been formed in it; and moved that the sub-committee appointed in 1898 to deal with questions on tuberculosis should be reappointed.

This motion was seconded by Dr. CARTER, and carried *nem. con.*

CASES.

Mr. C. G. LEE showed (1) a patient who had been accidentally shot, the bullet penetrating the inner and upper angle of the right orbit, traversing the orbit, missing the right eyeball, and finally lodging, as shown by radiographs, in the spheno-maxillary fossa. The boy was in perfect health, and, although the bullet was still in the head, except for a limited choroidal atrophy, appeared none the worse. (2) A youth, who had a piece of steel encapsuled with lymph lying at the posterior part of the retina. When first seen there was traumatic cataract, and the foreign body was discovered by the radiograph. The vision is now 6-12, and the eye quiet, so Mr. Lee has decided to make no attempt to remove the foreign body.

THE PATHOLOGY AND TREATMENT OF PNEUMONIA.

The adjourned discussion on Dr. Raw's paper was resumed.

Dr. HOPE said that the profession generally were agreed that intemperance predisposed to, and probably actually caused, the fatal results in many cases of pneumonia, but reference to this fact was not made in the death certificates. He had also seen in Liverpool that fatal pneumonia coincided with influenza epidemics, and that the fatality of these diseases was not associated so much directly with cold as with sudden changes of temperature.

Dr. MACALISTER, referring to the serum treatment of pneumonia, thought the argument that the crisis resulted from the production of the antitoxin, and that immediate relapse was thereby rendered unlikely was not maintained in the case of broncho-pneumonia, where fresh patches of consolidation succeeded one another, and that one attack of croupous pneumonia seemed to predispose to subsequent attacks.

Dr. ABRAM agreed with the specific infective nature of acute lobar pneumonia, and thought that our lines of treatment were unsatisfactory, mainly because they were

symptomatic, and hoped that the work of Washbourn Paul and others might give us a curative serum. He pointed out that Maraghamo has recently shown that the admixture of digitalis with nutrient media completely inhibits the growth of the pneumococcus, which afforded a valuable suggestion for curative treatment.

Dr. GULLAN noticed that the mortality in lobar pneumonia had been greater in 1899 than in the three years at the Royal Infirmary, and thought the type of the disease had been more severe constitutionally, and the local sign more extensive.

Dr. HAY referred to the influence of the alcoholic habit, and stated that out of 100 cases that he had watched two-thirds of the mortality was among the alcoholics. He considered that cardiac valvular disease, associated with pneumonia was of much less importance than degenerate myocardium, the condition of the latter being more important as a factor in the prognosis.

Dr. MACFIE CAMPBELL saw these cases at their commencement, and was responsible for their early treatment, and considered it was a much more fatal disease than it was twenty years ago; that he attributed to the influenza poison. Pleurisy was a frequent initiating symptom, and for that acetonite relieved the pain and fever. Salicylate of soda with carbonate of ammonia were his stand by; small doses of opium in the form of Dover's powder for the relief of pain. In order to clear up the point as to the influence of alcoholism on the mortality, it would be well if death certificates should pass straight from the doctor to the registrar, otherwise the practitioner was placed in an awkward position.

Dr. A. G. DAVIES thought that with careful nursing and treatment the death-rate from pneumonia should be under 10 per cent. He advocated the treatment by ammon. carb. and brandy, and would never use opium or other narcotics.

Dr. NATHAN RAW, in reply, said he had included all forms of pneumonia in his statistics, as it was impossible to classify them, he thought the death-rate of genuine lobar pneumonia was probably about 12 per cent. He thought no treatment had any effect in cutting short the disease, or to any great extent in influencing its progress. He found ammon. carb. the most useful expectorant and stimulant, and the combination of chloral and digitalis useful and soothing. Strychnine was the best drug in threatened heart failure. Oxygen was of little value, and as to alcohol, many cases did not require it, but in others it is necessary, and must be of good quality, and is most valuable.

BRADFORD MEDICO-CHIRURGICAL SOCIETY.

MEETING HELD TUESDAY, JANUARY 16TH, 1900.

Mr. W. HORROCKS, President, in the Chair.

Dr. EURICH gave a microscopical demonstration illustrating epitheliomata.

Dr. JAMES KERR read a paper on

INFLAMED CORNEAL ULCERS,

and showed illustrative preparations, together with the record of 100 cases treated by operation. The disease is most common in dusty weather and in people following dusty occupations. It is frequently traumatic in origin. Workers in soil and stone are the most frequent sufferers. Its incidence increases rapidly with age after 35. The spreading serpiginous ulceration, which is the most serious form, is due to pneumococci, which are confined to the cornea, the deep symptoms being due to the toxins produced. The galvano-cautery and paracentesis were held to be the best treatment, while scraping of the ulcer was not advised. Great importance was attached to early diagnosis and energetic treatment.

Dr. MAJOR related a

CASE OF TRANCE

which had a fatal termination. The patient was a woman, æt. 50, and was seen in consultation with Dr. Moorhead. She lay almost as one dead, there was intense pallor of the skin, and the muscles were relaxed. The respirations

were exceedingly shallow, and the heart's impulse was very weak. The conjunctival and other reflexes were absent, and she could not be roused to show any evidence of consciousness. The onset had been rather sudden three days previously; there were at first some transient spasmodic movements of the limbs. She continued in this state about three weeks, and finally died of exhaustion. Had been fed artificially by enemata and by nasal tube. Physical examination was negative; optic discs normal. Post-mortem examination revealed nothing except anæmia of the nervous system and organs generally. The case was diagnosed as one of death trance—a very rare affection. The symptoms appeared to depend on profound functional inhibition of the nerve centres. As regards diagnosis, uræmia, diabetic coma, cerebral tumour, and hæmorrhage must be eliminated, but a case of trance declares itself in a short time. Practical considerations in the treatment of such a case are:—Examination of urine for albumen and sugar to exclude uræmic and diabetic coma. Regular nasal feeding. Faradisation of the surface of the dry skin with electric brush is worth trial. The administration of amyl nitrite. The injection of normal saline either into cellular tissue or rectum. Should death appear to take place, we must be exceedingly careful before allowing anyone to act on that supposition. It is an acknowledged fact that patients have almost been put into their coffins while in a condition of trance. The Faradic current should be applied to the muscles. Muscular contractions cease three hours after death. (Care must be taken to see that the current employed will cause contractions of normal muscles.) A case is recorded by Rosenthal in which thirty-three hours after apparent death, the muscles continued to react to Faradism, and forty-four hours after the patient awoke.

Dr. CAMPBELL mentioned a case in which the patient had twice been put into her coffin and subsequently recovered.

Dr. MITCHELL showed a specimen from, and read notes on, a case of ectopic gestation. The patient was a married woman, æt. 38, had menstruated ten days before being seen; had suffered from indigestion for six weeks; pulse 80; temp. 98.8. The illness commenced August 6th with severe pain and vomiting; it was thought to be a case of autumnal gastro-enteritis. The legs were extended and the abdomen tympanitic. The next day the distension had increased, there was no pain or vomiting, bowels not moved. Temp. 101 degs., pulse 88. August 9th, much worse, coffee ground vomit. August 10th, pulse 104, no pain, patient pallid, doubtful dulness in flanks on percussion. August 11th, pulse uncountable, pallor increased; hæmorrhage was diagnosed. Patient died before anything could be done. Post-mortem examination was made surreptitiously. The cyst was removed. The whole peritoneal cavity seemed filled with blood.

France.

[FROM OUR OWN CORRESPONDENT.]

PARIS, February 17th, 1900.

PARA-APPENDICITIS.

M. BAZY, in speaking on this subject at the last meeting of the Société de Chirurgie, said that four years ago he alluded to cases of pericæcal abscesses, which seemed strange at the time to his colleagues, but since then several cases of the kind have been published. He had lately witnessed a very typical case. A young girl was brought to the hospital with a voluminous tumour in the right iliac fossa, which was considered as a case of appendicitis. The operation brought to light a mass of ganglions behind the colon, while the appendix was absolutely free from any lesion. The speaker placed a drain and the patient made a good recovery. He had operated also on a patient who three times over presented an abscess in the right iliac

region, and finally in the right hypochondriac; he suspected appendicitis, and, as a fact, the organ was diseased, and had probably provoked the abscess at a distance.

M. Juffier said that the difference between intestinal occlusion and the peritonitis of appendicitis was not sufficiently understood, and insisted on the value of the sensitiveness observed in the case of peritonitis of the recto-vesical or recto uterine cul-de-sac.

ANURIA.

At the Société Médicale, M. Renon communicated a case of absolute anuria with uræmia. A man, æt. 69, suffered from hemiplegia, voluminous heart, atheromatous arteries, &c. After complaining of pain in the lumbar region, the secretion of urine ceased, and for seven days before he died complete anuria was established but without any symptoms of uræmia. At the autopsy, the kidneys were found to be enlarged and filled with calculi. Another speaker said that it was only at the end of nine or ten days that anuria produced uræmic accidents.

PSORIASIS.

The following will be found useful in this troublesome disease:—

Salicylic acid, 3j;
Ichthyol, } 3ij;
Tar, }
Pyrogallic acid, 3iiss;
Lanoline, 3iv.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, February 17th, 1900.

SYMBLEPHARON.—TRACHOMA.

At the "Gesellschaft der Aerzte," Klein exhibited a young girl on whom he had operated for total symblepharon of the lower lid. The deformity interfered with vision as the ball of the eye was held tightly downwards at the pupillary attachment of the cornea. He separated the lid from the cornea, split it in two, and rolled each flap back, leaving the cornea to heal by granulation, uncovered. The movement of the ball is now complete with greatly improved vision.

He also brought forward a young man, æt. 22, with a trachomatous pannus, which impaired the vision as the symblepharon had done. He performed periotomy without effect, but succeeded in the Jequirity treatment, with the happy result of improved vision, though a high degree of myopic refraction still exists. He is in favour of applying the Jequirity treatment early in the disease as a preventive to the blennorrhæa inoculation.

Reus remarked that this operation for symblepharon was performed by Arlt.

EMBRYONIC DUODENAL ATRESIA.

Tandler next recorded the results of his research into the embryonic atresia in the duodenum. He found in ten embryos measuring from 10 to 20 mm. in length, the epithelium so prolific in the upper part of the small intestine as to quite obliterate its lumen. In embryos of 8 or 9 mm. in length, the canal has one layer of cells, which leaves the lumen quite distinct. When the embryo has reached 16 mm., the cells forming the core or stopper of the bowel become absorbed, leaving the bowel quite patent or normal by the time it has reached 20 mm. in length.

These results, he thought, had a practical bearing in the relative frequency of stenosis found in infancy. Out of 94 congenital cases of stenosis recorded, 33 are located in the duodenum, 55 in the jejunum and ileum, and 6 in the colon; while the proportion of length of the duodenum to the jejunum and ileum is as 5 is to 19. He thinks this persistent condition a more likely proximate cause of the stenosis than twisting of the duodenum, owing to the short mesentery, or foetal peritonitis, which has hitherto been accepted.

Fränkel said that he recently had two newborn children which died with stenosis in several places in the small intestine.

DOUBTFUL GUNSHOT WOUND.

At the Medical Club, Kienböck demonstrated a patient who seven years ago shot himself in both right and left temporal regions, but none of the cerebral symptoms occurred at the time to confirm any injury to the brain substance. About nine months ago the patient began to exhibit signs of mental weakness, which were rapidly followed by paresis on the left side with ataxia in the extremities. Suspicion fell on the gunshot wound as the original cause of this change. The Röntgen rays revealed two projectiles in the sphenoid bone in the left side of brain, one in the neighbourhood of the fissura orbitalis, the other at the base of the brain having been directed by the pterygoid process. Another bullet was found on the right side of the head, buried in the dura mater, which was evidently the cause of the nervous phenomena. The latter bullet was carefully removed but without any beneficial change to the patient, probably owing to the proximity of the motor centre, which had been injured beyond repair.

ACROMEGALIA AND DIABETES.

Schlesinger next introduced two cases with similar symptoms, though the one suffered from acromegalia, the other diabetes mellitus. From these phenomena he endeavoured to prove the connection of cause and effect with the close relationship which existed between them.

Teleky could not accept such a connection, and boldly maintained that the two diseases must have quite different causes of origin.

Sternberg admitted a close affinity in the two diseases but thought the acro-paræsthesia in Schlesinger's case was due to the climacteric period. He was quite prepared, however, to accept the theory that both of these diseases were due to some morbid change in the pancreas.

The Operating Theatres.

ST. PETER'S HOSPITAL FOR STONE, &c.

LITHOLAPAXY IN A CASE OF LARGE UNUSUALLY HARD STONE.—Mr. SWINFORD EDWARDS operated on a young and healthy-looking man, who had suffered from symptoms of stone for two years past. The patient had all the usual symptoms with the exception of hæmorrhage. Litholapaxy was performed under an anæsthetic. No. 12 A (Weiss) lithotrite was first passed, but the stone was too big to be seized by it, so a 12 B (Weiss) was introduced, but this was also not sufficiently large to grasp the stone, accordingly the meatus was divided in order to make room for one of Bigelow's large instruments; this at once grasped the stone, but the difficulty was to get and employ sufficient power wherewith to crush it. It was found impossible to do this at the first seizure

although great force was employed for several minutes after the instrument was locked to screw it up, the assistant holding the female blade with both hands, and the surgeon grasping the handle of the male blade firmly with a towel to protect the hand and employing all his force; but he was unable to produce any effect on the calculus. The stone was allowed, therefore to escape from the blades and having been seized again another attempt was made but in spite of others using their whole force it was still impossible to crush the calculus; the stone was therefore let go again, and seized afresh with the hope of getting it in a shorter diameter; this at last succeeded, as after several attempts the stone broke with a loud report after this the operation became comparatively easy, and the bladder was cleared in about 30 minutes. The *débris* showed that the stone was composed of a hard black oxalate interior coated over with a thin layer of uric acid; when dried the *débris* weighed just under 2 ozs. In spite of the rather rough manipulations necessary in the crushing of so hard a calculus hardly a drop of blood escaped from the bladder. Mr. Edwards said that if he had not succeeded on the third attempt, he had made up his mind to desist, and to do a suprapubic cystotomy.

It is satisfactory to record that a week after operation the patient is convalescent, not having had a bad symptom.

WEST LONDON HOSPITAL.

PYLOROPLASTY.—Mr. BIDWELL operated on a woman, æt. 50, who had suffered for three years from gastric ulcer, and had had several attacks of hæmatemesis, the pain being more or less persistent the whole time. The stomach was dilated and extended to about an inch below the umbilicus, no tumour could be felt in the region of the pylorus, the patient was fairly well nourished and not anæmic. The stomach contents had been examined chemically and contained excess of free hydrochloric acid. The abdomen was opened in the middle line above the umbilicus, and the stomach explored. The pylorus was found to be thickened and contracted but was not adherent to other parts; it was brought out of the wound. After an incision had been made into the stomach, the surface of the pylorus was found to admit only a No. 8 catheter, but not to be involved by any new growth. It was therefore divided horizontally with scissors, and the two angles of this incision brought together so as to convert the horizontal incision into a vertical scar. The suturing was done in two rows, the first of which was a continuous one involving all the coats of the stomach and duodenum, the second was a row of Halsted's quilled sutures passed through the peritoneal, muscular and sub-mucous coats. After the suturing was complete it was found by invaginating the stomach that the new pyloric orifice admitted the tips of three fingers. The pylorus was dropped back into the abdomen, and the abdominal wound closed with a continuous silk suture for the peritoneum and an interrupted silkworm gut for the rest of the abdominal wall. Mr. Bidwell said that this operation in non-malignant cases involves very slight risk, and has very little chance of allowing any fresh contraction of the pylorus to take place; it is, therefore, very superior to gastro-enterostomy, since in the latter operation contraction of the anastomotic opening is likely to occur after eighteen months. This untoward result happened in one of his

cases and necessitated a further operation. The other operation for a contracted pylorus, namely Loreta's, he remarked is also liable to be followed by recurrence of the stricture, although one case in which he had done this operation five years previously had suffered no further symptoms.

“SALUS POPULI SUPREMA LEX.”

WEDNESDAY, FEBRUARY 21, 1900.

RECONSTITUTION OF THE GENERAL MEDICAL COUNCIL.

THE deep-rooted conservatism of the medical profession is abundantly illustrated by the slow and gradual manner in which reform is brought about. In not a few instances, indeed, such as the control of hospital out-patient practice and the abolition of payments by hospital patients, it almost looks as if the day of achievement had been for ever relegated to the Ides of March. So far as the General Medical Council is concerned there is reasonable ground for hope that somewhere in the near future the constitution of that important governing body will be so altered as to bring it in touch with the interests and aspirations of the main mass of the medical profession. There is no need here to enlarge upon the shortcomings of the Council. Recent events have emphasised the conviction that after thirty-eight years of active life the Council has done little beyond raising and equalising the standards of preliminary and professional education. The funds of the Council are derived, as everyone knows, from the fees paid for voluntary registration by medical practitioners. The whole income of a body is thus provided by men who command only one-sixth of the voting power of the Council in the persons of the direct representatives. The majority of the members of Council, the remaining five-sixths, are appointed by the Crown, by the Universities, and the medical corporations.

In this way the fundamental principle that those who pay taxes should have the right of representative government is violated, and the result is that to-day the medical profession is practically governed by an autocracy. The problem now pressing for solution is how that indescribable state of affairs can best be remedied, if possible, by some well-considered and amicable scheme. For years past the Council has been urged to increase the number of Direct Representatives, and there can be no doubt that such an exercise of the power that lies in its hands would do much to conciliate adverse criticism. There is no prospect, however, of such a graceful act being performed for years to come, and the only hope appears to lie in the direction of skilfully applied outside pressure. The increase of Direct Representatives, then, should constitute what politicians would observe as one of the planks of the reformers' programme. Another proposal is that the representatives of the various Universities and medical corporations should be elected by the constituents of those bodies, instead of being nominated by irresponsible and autocratic councils as happens under present conditions. As all the world knows the control of the medical corporations has almost without exception drifted into the hands of a small knot of councillors in the election of whom ordinary graduates, licentiates and members have no voice. Twenty members of the Council are thus appointed, as against five Crown nominees and five Direct Representatives. The latter term implies on the contrary that the rest of the councillors are indirect representatives of the medical profession. As a matter of fact they are nothing of the kind, for by the nature of their nomination they go to the Council primarily to defend the interests of their own educational bodies, to the absolute exclusion of issues that are of vital interest to the main mass of the medical profession. Until the membership of the General Medical Council is vested in individuals who are in full sympathy and accord with medical men, there will be little chance of any lasting change for the better in the internal and external conditions of the profession. Clearly, if the twenty representatives of universities and corporations were elected by graduates, licentiates, members and fellows, the whole Council would be changed at one stroke from an autocratic anachronism to a representative body returned to power on a wide electoral basis. The prospect of such a consummation is sufficiently attractive to explain the enthusiasm with which it has been advocated in certain quarters. The legality of the proposed change seems beyond question, for when the Council was created in 1858 we believe we are correct in stating that there is absolutely no mention whatever made of the method in which the university and corporation representatives were to be appointed. As a practical step we should advise the formation of associations throughout the United Kingdom of medical men pledging themselves to leave no stone unturned in their endeavour to secure the right of electing the General Medical Council member of their own particular university, college, or society. The step is certain to be

strenuously opposed by the autocratic Councils, just as at the present moment they bitterly resent any attempt to limit their irresponsible government. The spectacle of the English College of Surgeons, to take one instance out of many, excluding the members from any voice in the management of the affairs of their corporation, constitutes a survival of government by a privileged class entirely out of touch with modern thought and feeling. Members of the college, who have hitherto been able to make little advance in securing their right, may do well to take up the election of a General Medical Council Representative as the chief article in their creed. Should it be found impossible to bring about this desirable reform, after a reasonable period of trial it will be well to approach Parliament with a view of securing legislation upon the point. That part of the agitation might be left to the British Medical Association, which has hitherto done remarkably little in the direction of protecting and advancing the consolidated interests of the profession. Meanwhile we commend the reconstitution of the Council by way of a universal enfranchisement of medical men as offering a prospect of the most peaceable and effectual revolution that could be desired by members of a noble and humane but, alas, unbusinesslike and disorganised, profession.

THE STERILISATION OF MILK.

It is generally agreed that cow's milk in its natural state may be the means of dissemination of various diseases, and latterly this subject has claimed much attention owing to the connection between the dissemination of tuberculosis and milk supplied by tuberculous cows. The importance of this aspect of the question cannot be too highly insisted upon, and especially for the reason that such a contaminated milk supply may do an incalculable amount of harm without exciting suspicion. In the days before the tuberculin test was employed, no doubt, tuberculous disease in the form mainly of *tabes mesenterica* was extensively conveyed to infants and young children. But even now-a-days this test cannot be absolutely relied on, and, therefore, the need is very great for the general adoption of some means by which milk is rendered incapable of transmitting disease. The method of sterilisation known as the Pasteurisation of milk is that which is deemed to be the least open to objection, but the drawback so far has been the difficulty of applying the process to milk in bulk. Small quantities of milk can be readily prepared in this manner, and many children in the present day are brought up upon sterilised milk. But in the abstract, of course, when milk is known in its natural state to be a frequent medium of the communication of disease, it can scarcely be disputed that every public milk supply in the kingdom should be subjected to some sterilising process. Indeed, the time seems to have come when further legal measures beyond those already in existence should be resorted to in order to ensure the wholesomeness of milk for public consumption. At present the law protects

the consumer against the adulteration of milk with water, the abstraction of cream, or its artificial preservation by means of boracic acid. But in view of the harm resulting from the contamination of milk with pathogenic micro-organisms, it becomes a serious matter whether the State should not compel every purveyor of milk to issue it in a sterilised form. If this were the case much diminution would result in all probability in the prevalence of those diseases with the dissemination of which milk is known to be largely concerned. Moreover, after all, the absence of bacterial contamination of milk is a much more important matter to the well-being of the community than its adulteration with water or boracic acid. For while the worst that can be said of these forms of adulteration is that they destroy, more or less, the nutritive qualities of the milk, on the other hand the pathogenic infection of milk frequently leads to the most serious outbreaks of disease. Practically, however, under present circumstances, the law affords no protection to the consumer so far as the latter contamination is concerned. All that can be done in the matter can only be done after harm has been caused. Take, for example, the instance of an epidemic of diphtheria which has been traced to an infected milk supply. As soon as the sanitary authorities have discovered the source of the disease measures are taken to prohibit the sale of the milk whence the infection has originated. In other words, this is clearly a case of locking the stable-door after the horse has escaped. Whereas, it is evident that in such a case, had the purveyor of the milk been compelled by law to sterilise it, in all probability, despite the fact that he might have had a case of diphtheria upon his premises, his milk supply would have remained free from infection. We understand in this connection that machinery has now been introduced making it a comparatively easy matter to sterilise milk in bulk, and an article appeared in the *Times* of last week stating that, in Bath, a milk company were supplying all their customers with sterilised, or pasteurised milk. The matter to which we here draw attention, we believe, is one which demands serious consideration in the interests of the public health; no one can dispute that prevention is better than cure, and as a preventive method against the dissemination of disease, the compulsory sterilisation of the public milk supplies would probably be attended with much benefit to the health of the community.

THE ABLE-BODIED WORKHOUSE INMATE.

THE expression of opinion which we find in the reports of recent proceedings of Irish Boards of Guardians gives us cause for the hope that the comfortable reign of the able-bodied pauper under Guardians administration is coming to an end. The Belfast Board has the honour to lead the crusade which, we trust, will tend to the extinction of the able-bodied pauper in its own workhouse, for we observe that, not trusting the stereotyped reports of officers,

it caused a barrack-yard inspection of them to be held so that each guardian could come and see for himself. Eight hundred men, whom the medical officer pronounced to be in perfect health, were lined up for inspection. Of these, six hundred were apparently over sixty years of age, and, therefore, could scarcely be turned out of the house to work in competition with younger labour, but were perfectly capable of earning their crust by some light work, such as fire-wood chopping or mat making within the House. In addition to these six hundred, 170 comparatively young men, every one of whom is as capable of bread-winning as any labourer in Ulster were presented, of whom seventy-two were supposed to be giving some value for their maintenance by small work in the House. One hundred remain who do not make any pretence of doing anything from year's end to year's end but walk about, eat, drink, and smoke pipes at the expense of the ratepayers. So much for the men. The condition of affairs as regards the women is much worse in Belfast; 42 of them are "separation" women, who amused themselves at the inspection by gibing at the Guardians and making criticisms on their personality. 79 were classed as nursery women, every one of whom had one or more children in the house. It may safely be predicted, as regards these classes of women in every workhouse in Ireland, that a considerable proportion are prostitutes *in esse* or *in posse*, and that a similar proportion of their children supported by the taxpayers are illegitimate. Belfast is but one out of 159 workhouses in Ireland in which the drones of the industrial hive are fattened by the half-starved working bees. During the greater part of the year able-bodied labour is at a premium, and wages are readily forthcoming which would keep the labourer (outside the public house) in comparative luxury. Probably neither the public nor the ratepayers appreciate the extent of this abuse, and it will be no harm to enlighten them. According to the Report of the Local Government Board for Ireland for the year 1899, able-bodied paupers to the number of 292,712 occupied the Irish workhouses. These, of course, included the floating population of tramps and people who were driven to seek shelter until they got work, but it may be taken from these figures that, on an average of every week in the year, an army of 5,629 able-bodied paupers occupy the Irish workhouses. The average cost of maintenance of each is about 3s. 8d. per week, which amounts to £1,031 per week or £53,612. We do not hesitate to say that the greater part of this large sum could be saved by a little watchfulness on the part of the Local Government Board and the guardians, and, perhaps, by some slight amendments in the existing Local Government law. The old inmates could be made self-supporting by giving them a little light work in or out of the House, the younger men and women could be induced to leave the House and earn their own bread by forcing them to do as much and as hard work in the House as would keep them outside, and most of the women

would take their children with them when leaving. How long are the ratepayers going to stand being sponged on by an army of lazy louts, male and female? Here is a chance for the glorious reformers who, under the new Local Government Act, have taken up the administration of Irish workhouses. Let them, instead of squabbling over a few shillings wrung from the sweat of the dispensary doctor, give their minds to the hundreds and thousands of pounds wasted in demoralising a small army of the Irish working classes.

Notes on Current Topics.

The Diet of the Poor.

AN investigation of considerable magnitude and importance is proposed to be carried out in Edinburgh by the Superintendent of the Royal College of Physicians' Research Laboratory, assisted by Dr. J. C. Dunlop and a number of other co-workers, into the nature and metabolic value of the foods ordinarily obtained, and usually consumed by the poorer classes, especially by the very poor. Last week the Superintendent, Dr. Noel Paton, addressed a letter to the Town Council, suggesting that the Council might take an official interest in the matter, and support this interest pecuniarily by voting £50 to allow it to be gone on with, as it was a subject of deep economic and humanitarian importance. The principal objects aimed at are the obtaining of data as to the sufficiency or insufficiency of the dietaries of the very poor for physiological requirements, as to the foods which they might secure at the least possible cost and, at the same time, of the highest nutritive value *per unit* spent on them, and as to the actual nature of the food-stuffs consumed, and when and how they are taken. The research will be conducted on the strictest scientific lines. The Town Council gave the subject their general benediction, and sent it to their Public Health Committee for consideration and report. The fact that the projected research is to be conducted under the most rigid rules of science, and supervised by experts already experienced in metabolic and dictative investigations, gives promise of results which must certainly be theoretically of value both from the side of political economy and from the view of the physiologist; whether they will suffice to convince that class which are most practically concerned with them is another and much more doubtful question. Before now the nutritive values of almost all articles of food have been theoretically determined, and their money value calculated from time to time in relation to current prices prevailing. The points which would offer most return, we should say, are those connected with modes of preparation of food and changes in utilisation, and those bearing upon the use or abuse of alcohol on domestic metabolism. The members of the class proposed to be placed under observation, who are most likely to agree to and fulfil the necessary conditions, will naturally belong to its well-conducted section,

the honourable though poor. An investigation into the actual yield in nourishment of the foods used by more disreputable or thoughtless families, if practicable, would be of interest as indicative of what men will be content to live on, although able to afford a better diet, so as to be able to spend a greater or less proportion of their earnings upon drink, tobacco, or amusement.

Sensory Acuity of the Female Genitalia.

A QUESTION has on various occasions been raised whether the tactile sense of a woman in respect of operations on the genitalia enables her to assert that an instrument has actually been passed into the uterus. In a recent number of the *Archiv für Gynäkologie* Dr. Calman gives the outcome of a series of observations which he has made on this point. He expresses the opinion that the sense of localisation is very imperfectly developed in the female genito-urinary system, the local differentiation between the urethra, bladder, and vagina being very uncertain. The sense of touch is markedly deficient, and a woman is unable to form any opinion as to the length of an object introduced, and although the thickness of the object is to some extent perceived, nothing approximating a correct estimate of its diameter can be made. There is, moreover, great obscurity as to the form and other characters of the object introduced, and even the number of objects is rarely gauged accurately. There seems to be no sense of touch in the portio vaginalis and in the uterus proper. This sense is comparatively well developed in and around the urethra, but in the vagina it is very feeble. The sense of temperature is also fairly well developed in the urethra, but much less so in the vagina, especially in regard to higher degrees of heat, while it is totally absent in the uterus. Pain is quickly perceived in the urethra, and in the cervix it is dull, but in the uterus itself painful sensations are often acute. Gynecologists are familiar with the fact that the uterus can be manipulated and even incised without causing pain, but movements imparted to the uterus as a whole are perceptible to the patient, not so much by reason of its inherent sensitiveness, as of that of its anatomical relations. So far as the vagina is concerned sensation appears to be limited to the vulva.

Company Pharmacy and Joint Stock Doctoring.

As the President of the Board of Trade, Mr. Ritchie, has introduced into the Commons the two Bills which passed the Lords last session promoted by the Lord Chancellor, it seems obvious that the Government is determined to pass them if the exigencies of Parliamentary work permit. These Bills are designated to amend the Companies' Acts, and, in the case of pharmacy trading, it is provided that no company or syndicate shall dispense unless under the supervision of a fully-qualified pharmacist. This provision, when supported by the Lord Chancellor in the Upper House last year by no means satisfied the chemists, because it allowed co-operative

companies and such like to carry on business freely, as dispensers by the agency of any number of unqualified assistants as long as one qualified man is in control and supervision. We sympathise with their protest, but we cannot see how the proposed new law can be resisted on public grounds. The second Bill, or portion of a Bill refers to joint stock doctoring and absolutely forbids any company or syndicate to carry on business as physicians, surgeons, or midwives, unless each and everyone of the members is a duly registered practitioner. Such a provision is essentially in conformity with the existing law. Every individual, whether member of a company or not, can practise as widely as he pleases, but always on his own responsibility, and subject to the disabilities which the Medical Acts impose upon unqualified practitioners, and the ostensible supervision of his practice by a qualified doctor cannot relieve him of these. If such practitioner attempts to shield the unqualified man by signing death certificates, or performing other function which is reserved for the legitimate profession, he forthwith brings himself within reach of the law, and can be debarred by the Medical Council. It is thus obvious that the cases of the chemist and the doctor are not on all fours, and the chemist should not be jealous if Government makes a distinction which the existing law has already made.

The London Asylums Board and the War.

PATRIOTISM is an admirable quality whether displayed by the individual or by public bodies. At the same time, like all emotional conditions, it should not be allowed to run counter to the dictates of sober judgment. Miss Atkins, late matron of the Park Hospital, has furnished an object lesson to the philosophic citizen by sending in an application for leave of absence to the Metropolitan Asylums Board, in order that she might join a hospital in South Africa. A stormy discussion followed, but eventually the application was refused on the ground that the first duty of the Board was to deal with their own sick at home. The resignation of Miss Atkins was then handed in and accepted by a large majority. Her action can hardly be upheld, as there is no dearth of candidates for nursing posts at the front, and it was open to Miss Atkins to resign her post before going out, without asking the ratepayers to pay for her services during an uncertain period of absence. The case does not fall within lines similar to those that regulate the volunteering of soldiers.

A Mistress's Responsibility.

It is to be feared that the law in respect of the use of public vehicles for the conveyance of persons suffering from infectious diseases is not as generally known and acted upon as, in the interests of public health, one could desire. Only last week a lady living in the suburbs of London was summoned for having caused her servant, who was suffering from

diphtheria, to be taken to the hospital in a cab, and though she escaped on the technical ground that she could not be considered to be in charge of her servant, it was abundantly evident that in directing the young woman to be thus transported the lady was acting in blissful unconsciousness of the fact that in so doing she was rendering herself liable to prosecution. What is even more remarkable is that one medical man who saw the patient actually suggested that she should be taken to the hospital on the top of a tramcar, a course which would possibly prove more detrimental to the patient than to the other travellers. It would be well for sanitary authorities to take steps from time to time to bring the principal laws relating to the management of patients suffering from infectious diseases to the notice of those whom it may concern, for while a small number of persons may sin from indifference or sheer wilfulness the majority undoubtedly err from ignorance or thoughtlessness. Especially does it behove medical practitioners to make it clear to those in charge of such patients that by adopting any other mode of conveyance than an ambulance, unless they are prepared to pay for the subsequent disinfection of the vehicle, they will render themselves liable to the penalty in that case made and provided. There is the less excuse for neglect, seeing that ambulances are specially provided for the purpose, and are available at any hour of night and day.

Fees for Urgency Police Calls.

WE are pleased to be able to state, on the strength of a letter which we publish elsewhere, that the Police authorities of the City of Bradford have revised the scale of remuneration allocated to practitioners who place their services at the disposal of the Police. The original fees were half-a-crown for a day visit, and five shillings (!) for a night call—sums which gives a poor idea of the value attached to such services. Under the revised scale the fees will be five and ten shillings respectively. This highly desirable modification is the outcome of an interview between a delegation of members of the Bradford, and the West Riding and Bradford, Medico-Ethical Societies, and the committee of the City Council, and it is gratifying to find that a satisfactory *modus vivendi* was arrived at.

Alcohol in Carbolic Acid Poisoning.

CARBOLIC acid, even in comparatively small doses, is a very violent poison, acting as it does, locally in virtue of its caustic effects on the membranes with which it comes into contact, and on the organism at large as a powerful depressant. According to an article which appeared in a recent number of Merck's "Archives," the best treatment for carbolic acid poisoning is the administration of several ounces of whisky, brandy, or other spirit, suitably diluted. This combats at the same time the irritating local action of the acid and its intensely depressing influence on the nerve centres. The next step is to wash out the stomach through a soft rubber tube, syphoning in the usual way, and this process may

advantageously be repeated several times at short intervals. We shall then have reached a stage at which the exhibition of sodium sulphate is indicated, and a drachm or so of the salt dissolved in a wine-glassful of water should be swallowed. Statistics of the results of this treatment tend to show that it is attended by a large measure of success, and in view of the extreme fatality of this method of poisoning and its exceeding frequency we commend it to the notice of our readers.

What is Milk?

THE first step towards the efficient control of the purity or quality of any article of food clearly lies in establishing a standard. In the case of milk, no satisfactory "normal" has yet been fixed, and the decision has consequently been left roughly to the opinion of various more or less eminent chemists. The obvious injustice of such an indeterminate state of affairs was shown, if we may accept the evidence for the defence, in a recent trial for milk adulteration. The defence stated that a sample of milk taken direct from the cow was sent for analysis to Somerset House, and there certified to be adulterated with 10 per cent. of added water. Whether the assertion, presumably supported on oath, influenced the verdict or not is not clear from the short report of the proceedings given in the daily newspapers, but the suggestiveness of the matter is great. Here we have a Government Office, always supposing the defendant's evidence to be true, stultifying its own analysis and authority. The fact of the matter is that the milk of a cow may vary within wide limits according to the food, the state of health and other circumstances of environment affecting the animal. For a long time past dissatisfaction has been expressed in the metropolis with the methods of the Somerset House Analytical Department, and small wonder if they possess no scientifically established standard for so important an article of food as cow's milk. An enormous number of interests are involved in the milk trade as concerns farmer, dairyman, and consumer. A great many prosecutions take place for adulteration of this food-stuff, and were it once proved that the official analysis of milk taken straight from the cow was untrustworthy the possibility of successful defence against prosecution would be greatly increased. The importance of the question has been recognised in Parliament by the appointment of the Milk and Cream Standards Committee, which is about to sit. It has been appointed by the President of the Board of Agriculture to inquire as to what regulations may advantageously be made for determining what deficiency in any of the normal constituents of milk and cream, or what addition of extraneous matter or proportion of water in any sample of milk (including condensed milk) or cream, shall raise a presumption that the milk or cream is not genuine. It would be reassuring if the Board were to extend its inquiries into the organisation of the Analytical Department at Somerset House. Meanwhile, it is somewhat difficult to answer the question, "What is milk?"

Emaciation in Hysteria.

EMACIATION is always a serious condition, and when marked and progressive, is generally indicative of some organic disease, which is not unlikely to prove fatal. Its connection, however, with hysteria has been noted by Osler. He had a fatal case under his care in which the emaciation was so extreme that the patient, a girl, weighed only forty-nine pounds, but no post-mortem lesions were found. Another case has been recorded by Beath, of Winnipeg. The patient was a girl, æt. 18, who when she came under the author's care, weighed with heavy boots, clothing, hat, and shawl forty-four pounds. She had never menstruated, and her organs were in every respect normal. The curious point was, however, that despite the extreme emaciation which was present, she was able not only to come ten miles in a lumber wagon sitting upon a backless seat, but to walk up a flight of stairs immediately afterwards to see the doctor. Her appearance was that of a jointed skeleton covered over with a tightly-drawn skin. There was no question as to the hysterical nature of the case. The treatment adopted was partial segregation for four weeks and Weir-Mitchell treatment, under which she gained seven pounds. Ultimate recovery followed, and the patient is now plump, active, and enjoying life. The case had been diagnosed as one of "consumption," and the parents had been led to believe that recovery was hopeless. A point of interest, however, in these cases is, to what is the emaciation due? This is a difficult matter to determine, and no satisfactory explanation has so far been forthcoming. Anæmia, of course, is present, but defective assimilation, even the food taken, would presumably be mainly concerned in bringing about the wasting.

Survival of Functions after Death.

DR. LABORDE has found by direct experiment that the functions of the tissues and organic elements of the body do not at once fall into abeyance with the apparent death of the subject, that is to say, with the cessation of what we are accustomed to describe as the vital functions. The respiratory reflex caused by rhythmical traction on the tongue, for instance, can be obtained for a variable period after the pulse and breathing have ceased, and it is to this ephemeral prolongation of functional activity that Dr. Laborde attributes the possibility of bringing back to life persons who have ceased to live some time before.

Thyroid Extract in Non-union of Fractures.

IN certain cases of non-union of fractures the internal administration of thyroid extract has determined consolidation, instances of which were recently brought before the French Society of Surgery by Dr. Potherat. Inasmuch, however, as non union of fractured bones is dependent upon a variety of physical and mechanical causes it would obviously be idle to expect the same treatment to effect an equally good result in all. In any case the suggestion adds another method to our *repertoire* in dealing with a very troublesome class of cases.

The Prince of Wales and Sir William MacCormac.

THE Prince of Wales at the meeting of the General Council of his Hospital Fund last week, paid a graceful tribute to the patriotism of Sir William MacCormac, who is now at the front. "I may say," said His Royal Highness, "that one of the members of our Council, the President of the Royal College of Surgeons, Sir William MacCormac, is, as you are all aware, now at the seat of war. At his time of life the performance of the arduous duties that this necessitates, reflects, I think, great credit on him, and gives the utmost satisfaction to all who know him." In these graceful words the Prince refers to a point which has already caused not a little comment favourable to the action of the President of the English College of Surgeons. He has reached a time of life when leisure and repose may rightly be claimed after many years of professional work; but despite this, Sir William elects to undertake the hardships and risks of a campaign, and discharge duties which would be arduous even for those who have youth on their side.

Another County Court Judge on Medical Fees.

WE are glad to see that a London County Court Judge, his Honour Judge Stonor, of the Marylebone County Court, has had an opportunity of amending in some measure the ignorance or prejudice respecting medical fees displayed recently by Judge French. He found that the charge per visit, with medicine, to a publican, of five shillings, was not excessive, and the plaintiff, practising in Bayswater, won his case. The plaintiff is to be congratulated upon the fact that his case was heard by Judge Stonor and not by Judge French, for judging from the idea prevalent in the mind of the latter as to the value of a medical man's services, there is no saying what the result would have been. This fact has become so notorious in the district of the Bow County Court, that some practitioners rather than expose themselves to the decision of the presiding legal luminary, prefer to settle their cases as best they can without an appeal to his judgment.

Achromatopsia for Blue in Bright's Disease.

BLINDNESS in respect of blue rays is a symptom which is common to many forms of retinitis, but it appears to be specially associated with chronic interstitial renal disease. Attention was called to this fact in 1897 by Drs. König and R. Simon, and since that time further observation has confirmed their results. Quite recently Dr. Gerhardt reported three cases in which this phenomenon was present in patients suffering from granular kidney, one of them being of plumbic origin. This point merits more careful investigation, since it may possibly furnish us with another diagnostic element in chronic renal affections. In all the cases blue appeared to the patients as black, the disability in some instances disappearing with an improvement in the functional condition.

War, Commerce, and Physic.

THE present campaign in South Africa is an altogether novel departure in that it is being carried on to some extent by voluntary subscription. Donations in hard cash, and in articles such as woollen garments and chest protectors, must always be welcome, but there is a comic element, the only one as things go, in the avidity with which manufacturers of out-of-the-way medical and pharmaceutical appliances and preparations have availed themselves of the opportunity to air their patriotism, and secure a gratuitous advertisement for their pet products. One would think that a notice had been displayed at the War Office to the effect that "rubbish may be shot here." The inventor of a patent truss sends an assortment of his goods to the front, a soap manufacturer, fancying no doubt that the Government would probably overlook such a detail, hastens to send a few tons of his unquestionably useful product, and the vendors of pills, liniments, and cough tablets offer munificent supplies. All the antiseptic and healing ointments yet devised are forced upon the jaded attention of the authorities, and even pocket-handkerchiefs are not forgotten, embellished, as the case may be, with patriotic pictures or scripture texts. What the authorities in South Africa will do with this *olla podrida* it is difficult to say, but we trust our soldiers will not be persuaded or cajoled into experimenting on themselves with any of the internal or external remedies so generously placed at their disposal by enthusiastic but shrewd donors. The probability is that very little of this miscellaneous assortment will ever reach the troops. The lots will be warehoused for a time in some out-of-the-way corner here, or will be dumped down on the quays at Durban and left to moulder.

Salvation Shelter and its Sick.

THE danger to the public arising from the methods of the Salvation Army Shelter authorities has been demonstrated by the litigation that for the last seven or eight years has dragged its slow length through the law courts. Fortunately, all that is now ended by the final decision that places the shelters within the wholesome provisions of the Common Lodging Houses Acts. It is no small matter of wonder how persons professing high religious ideals should resist to the utmost of their power the attempt to protect the health and the lives of their fellow creatures. Philanthropy of this emotional kind, however, especially when it labours under the fatal shadow of semi-commercialism, is apt to develop strange inconsistencies. That tendency is further illustrated by the treatment of a dying inmate of the Holborn Shelter, according to statements made last week before a London coroner. It appears that the unfortunate man had been staying on and off in the Shelter for a fortnight, and was found very ill one morning by a room orderly. He was got out of bed and dressed by a Shelter official, who then took him off to the Relieving Officer. The latter had him at once carried in an ambulance to the infirmary, where he died a few hours after admission. The fact of a medical man not having been called in to see deceased

was strongly commented on by the coroner, who advised the officials present connected with the Shelter in future not to try and save the Salvation Army's money in that way. The appointment of a regular visiting medical officer would do something towards restoring the rudely shaken confidence of the public in these Shelters. What with vermin, the spread of infectious disease, bad sanitary environment, and absence of medical attention to sick inmates, the need of stringent control of night refuges is more than apparent.

War Service as the Student's Equivalent for Hospital Attendance.

WE note that it has been referred by the Council of the Royal College of Surgeons of England to the Committee of Management of the London Conjoint Examinations, to consider and to report to the two Colleges on the recognition of the services rendered by medical students at the seat of war as a part of the hospital curriculum. It is quite possible that the work which a student may see at the seat of war will be a fair equivalent for a period of hospital walking in London, but the recent spreading of the net for grammar school boys and other small fry inspires us with a suspicion that this is another baiting of the crib for the unfledged birdlings of trans-London teaching centres.

DR. DAVIDSON, who keeps a drug shop at Shettleston, Glasgow, was charged last week with having sold laudanum *per* his unregistered assistant in contravention of the Pharmacy Acts. The charge was preferred by the Pharmaceutical Society, and the defendant fined £3, with two guineas costs.

It is not at present intended to accept for war service members of the Volunteer Medical Staff Corps who do not fulfil the conditions laid down in the Special Army Order of the 5th inst., but should the numbers obtained fall short of those anticipated the subject will be further considered.

PERSONAL.

DR. LANGFORD SYMES is also a candidate for the vacant post of Registrar-General for Ireland.

THE PRINCE OF WALES, representing Her Majesty, has promised to lay the foundation of the new buildings of the Newcastle Royal Infirmary on or about June 15th.

SIR PHILIP SMYLY has been re-elected by the Royal College of Surgeons in Ireland as the representative of the College on the General Medical Council for the ensuing year.

WE regret to learn that Major Walter Riddle, M.D., Royal Army Medical Corps, was murdered by natives in Burmah while engaged in his duties as medical officer in charge of our frontier forces in that country.

SURGEON-GENERAL WILLIAM TAYLOR, C.B., Principal Medical Officer on the staff of the Commander-in-Chief in India, has been awarded a good service pension of

£100 a year as the reward of 35 years' active service in the army.

A LODGMENT for lady medicals has been effected in Guernsey by Mrs. Mary Bishop, L.R.C.S. Edin., who, ten days since, was admitted by the Royal Court of the island to practice her profession there. She is the first lady doctor who has obtained such permission, but there is another lady practitioner who, being a native, had no necessity to apply.

Dr. HOPE, principal Medical Officer of Health for the City and Port of Liverpool, presented on behalf of the subscribers last week, a massive silver inkstand to Dr. Ed. P. Manley, the assistant Health Officer, in token of appreciation of his services, prior to his departure for London, where he has received an appointment under the Local Government Board.

Dr. J. PURVES STEWART, M.A., M.D., M.R.C.P., assistant physician to the Westminster Hospital, has been appointed Physician to the Imperial Yeomanry Hospital, and, in company with Mr. Charles Stonham and a staff of dressers and clinical clerks, will shortly proceed to the front. Dr. Purves Stewart is an Edinburgh man, and has only been on the staff of the Westminster Hospital for about a year, but his temporary loss will be severely felt, as he is a good teacher and most enthusiastic in his work.

No appointment to the position vacated by the death of Dr. Grimshaw has yet been made, nor are there, as far as we know, any new developments. It is suggested and currently believed, that the functions of the office will be divided, and that, whosoever may be the Registrar-General for Ireland, there will also be a Medical Superintendent of Statistics. If such appointment be made a re-arrangement of salaries will probably be necessary, as the Treasury will not be likely to tolerate any additional outlay on the Department.

MR. VICTOR HORSLEY AND THE GENERAL MEDICAL COUNCIL.

We are asked by the Hon. Secretary of the Bradford and West Riding Medical Union to publish the following resolution, which he informs us was carried *nem. con.* at the general meeting held on the 15th inst.:-

"The members of the Bradford and West Riding Medical Union beg to offer their hearty congratulations to Prof. Victor Horsley, F.R.S., one of the direct representatives of the medical profession on the General Medical Council, on the success with which he has struggled to defend the interests of medical practitioners against the continued neglect shown by the representatives of corporations on the General Medical Council, and hope that the medical profession may long continue to have the advantage of being represented on the Council by a gentleman so distinguished alike by scientific attainments and by remarkable energy and skill in pushing the work of reform, which is so much needed."

THE PROFESSORSHIP OF SURGERY IN QUEEN'S COLLEGE, CORK.

THE position vacated by the recent death of Dr. Stephen O'Sullivan has been filled by the appointment thereto of Dr. C. Yelverton Pearson, surgeon to the North Charitable Infirmary and to the Cork Hospital

for Women and Children. As a student he took a scholarship and gold medal in the College, and served honourably after graduation as a Demonstrator of Anatomy and Professor of Materia Medica in it. He is a Fellow of the London College of Surgeons, and has twice occupied the presidential chair of the Cork Medical and Surgical Association, his inaugural address on abdominal surgery having been published in the MEDICAL PRESS in 1897. He has also been a frequent contributor to the proceedings of the Royal Academy of Medicine of which he is a Fellow.

THE SURGEONCY OF THE QUEEN'S COUNTY INFIRMARY.

THE hearing of the law arguments as to the validity of the recent election of Dr. Blaney to be Surgeon in place of Dr. William Jacob, whom the new Board of Governors suppose that they have dismissed, was listed for the sitting of the High Court in Dublin for yesterday (Tuesday.) The question at issue is whether these Governors have power to dismiss a surgeon, having regard to the new Local Government law and the special circumstances of the case. We understand that a heavy bar has been retained. For the Governors, Mr. T. M. Healy, Q.C., M.P., Mr. Dudley White, and Mr. Falkiner, Q.C. For Dr. Blaney, The MacDermot, Q.C.; and for Dr. Jacob, Mr. J. M. Campbell, Q.C., M.P., Mr. Ronan, and Mr. Brunskill.

Scotland.

[FROM OUR OWN CORRESPONDENT.]

WAR HOSPITALS FROM SCOTLAND.—Scotland has recently done her duty nobly for the Empire in many ways, in flesh and blood and in kind. She still further proposes to contribute to the Imperial resources by sending out two fully-equipped base hospitals to South Africa, a National Red Cross Hospital, and another almost entirely raised in her metropolis, Edinburgh. The first is to be representative of all Scotland, the second of Edinburgh alone. Notwithstanding the large sums already given by the citizens of Edinburgh to the various funds in connection with the war, only a few days after the appeal for this new scheme appeared a total of £13 073 had been subscribed out of the £20,000 asked for. The Committee in charge of the scheme include:—The Lord Provost, Earl of Hopetown, the Lord President of the Court of Session, the Lord Justice Clerk, General Chapman, the Provost of Leith, the Master of the Merchant Company of Edinburgh, Sir William Turner, M.B., P.M.C., Professor Chine, Dr. Joseph Bell, and Colonel Warburton, R.A.M.C. The National Hospital has its origin in the St. Andrews Ambulance Association, now recognised as an official branch of the Red Cross Association of Great Britain. The Marquis of Breadalbane acting as President, and Dr. P. A. Toving as the Chairman of the Edinburgh branch.

THE CHAIR OF PRACTICE OF PHYSIC IN THE UNIVERSITY OF EDINBURGH.—The supporters of the candidatures of Drs. Wythie, Bramwell and Gibson for this Chair have severally issued testimonials for signature to members of the profession in Edinburgh, and those elsewhere connected with the University, on behalf of each applicant. Drs. Alexander James, and Robert A. Fleming have also, we understand, sent in applications.

INFLUENZA is still rife in Edinburgh, and many cases of influenza pneumonia have been, and still are, met with.

A LABOURER, æt. 32, of Walton-on-Thames, died of tetanus at St. Thomas's Hospital last week, as the result of a wound of the thumb sustained while snow-balling on the 3rd inst.

Correspondence.

We do not hold ourselves responsible for the opinions of our correspondents.

MEDICAL MEN AND URGENCY CALLS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The Watch Committee of Bradford have inaugurated a very striking and useful era for general practitioners. The area of this city has been recently much enlarged, and the police street accident work much increased under the Council's jurisdiction. To meet this the town clerk sent notices to all medical men in the city asking them to attend, on request of the police, who are armed with proper forms, any accident nearest to their homes, at the following scale of charges:—

	s.	d.
Day-time, 9 a.m.—9 p.m.	5	0
Each call in night-time, 9 p.m.—9 a.m. ...	10	0
Petty Sessions Court at Town Hall	10	6

The compliment is highly appreciated by the doctors here (showing a recognition of the individual rights of a general practitioner), and it is hoped that guardians and other representatives may act in a similar public spirited way. The first terms offered by the Watch Committee were about half those now offered; this result of doubled fees was brought about by the joint effort of the two Ethical Societies here acting in concert. These changes leave the police surgeon unaffected, save for an increase in his salary and fees.

I am, Sir, yours truly,
PRECY G. LODGE.

THE DISPENSING OF MINUTE DOSES OF ALKALOIDS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The erroneous impression conveyed in recent issues of THE MEDICAL PRESS AND CIRCULAR that retail pharmaceutical chemists are incapable of dispensing minute doses of potent drugs having been brought under the notice of the Council at their last meeting, I have to say that, on behalf of the licentiates of the Pharmaceutical Society of Ireland, my Council protest against such statements, and they have directed me to hand you the accompanying report of their discussion on same, and to request you to publish it in your next issue.

I am, Sir, yours faithfully.

ARTHUR T. FERRALL, Registrar.

Dublin, February 17th, 1900.

[We trust it will not be considered disrespectful to say that, as we have already twice pointed out that we never made the statement herein attributed to us, we think it unnecessary to repeat the disclaimer now. We submit that the Council of the Pharmaceutical Society might advantageously have—by inspection of our columns—acquainted itself with what we did say before sending us this communication.—ED.]

THE DEATH-RATE OF LIVERPOOL.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I shall esteem it a favour if you will kindly give me your reasons for making the following statement in reference to the recent high rate of mortality in Liverpool, viz.:—"Although an influenza epidemic had claimed many victims, the returns nevertheless indicated that only one-fifth of the increase could be attributed to this disease. It has therefore been pertinently asked, if only this small proportion of the increase could be assigned to influenza, how was the remaining percentage of the augmented death-rate to be accounted for? No satisfactory reply to this query has, so far, been forthcoming. . . . It has been said that the city is the resort of the residuum of the working classes, who take shelter within its confines when they cannot obtain work elsewhere. But it does not appear that the death-

rate is especially high among the classes in question, and therefore this explanation does not seem to us to be adequate, at all events so far as Liverpool is concerned."

I may state for your guidance that since the sudden rise in the death-rate in the third week of December, influenza has been very prevalent, and although the number of deaths attributed solely to it have not exceeded twenty-four in any one week, yet the associated pneumonia and diseases of the respiratory system have been very great; moreover, the deaths in workhouses and hospitals since the period in question have furnished no less than 26.5 per cent. of the total.

You may perhaps have noticed that Brighton, which has but a fraction of labouring population, has had during the recent prevalence of influenza a far higher death-rate than has been recorded in Liverpool within my memory.

I am, Sir yours truly,

E. W. HOPE,
Medical Officer of Health.

Public Health Department, Liverpool,
February 10th, 1900.

[While we have pleasure in publishing Dr. Hope's letter, it is not altogether easy to understand the drift of his inquiry. It is not clear to what particular "statement" he refers in asking for "reasons." The general aim of our paragraph was to draw attention to a fallacy in influenza returns, which is borne out by Dr. Hope's figures. Then, again, the theory as to the possibility of a labouring population causing an increase of influenza mortality was dismissed in our remarks as unsatisfactory. We cordially agree with Dr. Hope's implied belief that the deaths from the disease in question are mainly due to secondary causes. A formal communication upon this most important subject from so able a statistician as Dr. Hope would be welcome to our readers. The abnormally high death-rate of Liverpool is generally attributed in part to poverty and overcrowding and the environment incident to a large labouring population.—ED. M. P. and C.]

CONTAGIOUS DISEASES ACTS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I am sure your readers will be interested to see a *précis* of M. Fournier's views respecting the prophylaxis of syphilis. M. le Dr. Alfred Fournier, Professeur à la Faculté de Médecine de Paris, Ricord's successor and Physician to l'Hôpital St. Louis, has recently (November, 1899, shortly after the Brussels Congress, which he attended) formulated his views as to the prophylaxis of syphilis in a paper which he has presented to the Académie de Médecine de Paris. (a) He says the best of all methods of preventing syphilis is by the inculcation of moral and religious principles, in other words, as M. Ricord has remarked, "the only way" to escape syphilis is to avoid the risk of catching it; syphilis does not fall down from heaven, and no man need inoculate himself unless he deliberately chooses." As to the actual system of the Police des Mœurs in Paris—a system which we are asked to copy in England—M. Fournier, and no higher authority can be quoted, declares that it is "insuffisante, impuissante et caduque" insufficient, powerless, and rotten to the core. This is, he says, owing to the fact, on which I have laid stress, that the police can only bring under control a few women (two or three thousand), while six, eight, and ten times as many escape control and spread syphilis among the population of Paris; the police, he says, do the little they can, and we must thank them, but it is impossible for them to check the spread of venereal disease. "Elle est impuissante à indiquer le flot débordant des contaminations vénériennes."

M. Fournier adds: little as the police have done, they

will do still less in the future, and for the following reasons:—1. Because the licenced brothels are steadily and inevitably diminishing in number; women cannot, much as the police try, be driven into them and kept there prisoners. 2. Because of the immense increase of clandestine prostitution which is constantly increasing. 3. Because of the strong public feeling which is opposed to the arbitrary action of the police (upwards of twenty thousand women are arrested every year in Paris, outside of all legal forms, and may be detained from a few weeks to a year); and 4, because of the demonstrated powerlessness of the system to prevent syphilis or diminish venereal diseases, in proof of which M. Fournier says we have syphilis with us now as we have always had it. "A-t-elle par exemple jamais diminué de fréquence depuis une quarantaine d'années que j'en ai fait l'objet de mes études spéciales? Impossible à moi de le croire d'après ce que j'ai de mes yeux vu! A-t-elle au contraire augmenté de fréquence? Je le crois fermement"—an impression which is shared by M. Fournier's colleagues, who have unanimously declared "Des syphilitiques on en voit aujourd'hui partout et plus que jamais." M. Fournier adds, syphilis is flourishing in Paris to-day; it abounds and surabounds; the special hospitals are not large enough for the numerous cases, which overflow into the general hospitals. All this shows how impotent are the Police des Mœurs, so far as the repression of syphilis (the only venereal disease of any consequence) is concerned. He adds, "Telle est en effet la stricte vérité des choses." All this is evidently the direct result of the system we are asked to introduce into England. With what object? To stamp out syphilis. Is it not too ridiculous?

I am, Sir, yours truly,

C. BELL TAYLOR, M.D.

THE RISKS OF UNOPERATED FIBROMYOMA.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Will you permit me to correct an error which appears in my paper on "The Risks of Unoperated Fibromyoma," in your last week's journal. The specimen, No. 2951A. in the St. Bartholomew's Hospital Museum is not, Dr. Griffiths informs me, taken from a case of uterine fibroma but of carcinoma. The specimen is, however, still very worthy of study as showing, perhaps better than any museum specimen with which I am acquainted, the ravages caused by pelvic peritonitis and the difficulties which it imports into any case requiring surgical interference in that region. Inasmuch as such pelvic peritonitis is a comparatively rare thing in carcinoma, whilst extremely common in old fibromyomata complicated, as it so often is, with inflammatory changes in the appendages, the lesson it teaches is very useful in connection with this subject.

May I ask you to make this correction in your next issue.

I am, Sir, yours truly,

G. STANMORE BISHOP.

316, Oxford Road, Manchester,
February 19th, 1900.

Obituary.

DR. WILMOT, OF DUBLIN.

THIS most estimable and respected gentleman died at his residence in Kingstown on the 17th inst., one of the few remaining links between Irish surgery in the past and in the present being thus severed. Samuel George Wilmot commenced the study of his profession at Steven's Hospital under the guidance of Abraham Colles, James Cusack, and others, whose skill and industry made Irish Surgery of that day notable. He took his first qualification in 1842, served as resident surgeon of his hospital, and through all grades until he became its

consulting surgeon. His M.D. was derived from the University of Aberdeen in 1846, and he took the Fellowship of the Royal College of Surgeons of Ireland in 1844, becoming ultimately its president. He was a special authority on affections of the urinary system, and wrote several papers on that subject. Dr. Wilmot was greatly esteemed by his brethren as a most kindly and honourable man, and his death leaves many regrets.

Literature.

TAYLOR'S EXTRA-UTERINE PREGNANCY. (a)

WE accord a hearty welcome to the appearance in book form of Mr. Taylor's Ingleby Lectures on extra-uterine pregnancy. These lectures formed the most important contribution to the subject that had appeared for some years; and in their present form they are fuller and more complete than when they were delivered. On some points Mr. Taylor has done pioneer work; especially in the elucidation of the difficult question of abdominal pregnancy, and the ways in which it may arise out of a pregnancy primarily tubal and secondarily mesometric. The distinction which he draws between the anterior ligamentary or sub-peritoneo-pelvic, and the posterior ligamentary, or retro-peritoneal forms of pregnancy was new and important. The two forms had been already described, but they were not recognised as definite modes of development of ligamentary pregnancy. Mr. Taylor rejects the view that a pregnancy may be primarily abdominal, contending that in every case the first seat of impregnation is the tube. In connection with this we may mention his view that invagination occurs normally in the tube; this is at variance with the view of some authors that impregnation only occurs normally in the uterus, and that if it occur in the tube it leads to extra-uterine gestation. Ovarian pregnancy is regarded by Mr. Taylor as theoretical only; he points out that careful elimination of several fallacies is necessary before the fact of ovarian pregnancy can be considered as established in any given case. The directions for operative treatment are given fully, and form a trustworthy guide to the intending operator. We can say without hesitation that no surgeon or gynaecologist can afford to be without this important monograph. On one point our criticism must be unfavourable, and that is in regard to the illustrations. Many of these are very poor, and quite unworthy of the excellence of the text. We hope that the reception of the book may be such as to call forth another edition; and that when this is contemplated the illustrations will be brought up to the standard required by the importance of the work.

BISSET'S PSYCHOLOGY OF REASONING. (b)

M. BISSET alleges that his psychology of reasoning is based on experimental researches in hypnotism. The psychic revelations of the hypnotic state are, indeed, very suggestive, but their value as data in a constructive system of psychology must, in not a few instances, be doubtful, not only because of the personal equation in the subject, but in the observer as well. The first chapter, dealing with the syllogism and the definition of perception, is clear and explicit. He disputes the syllogism of the ancient logicians, which affirms that a group of three propositions, the first of which is general, constitutes a proof, and in doing so he but re-echoes Stuart Mill. His aim is to show further that numerous, though always particular facts are the real premises of reasoning, the real proofs of the conclusion, "so that the conclusion is not contained in the premises; it is distinct from them, and adds something more to them. This idea, which is so appropriate, simple and natural, explains how reasoning constitutes a development of know-

(b) "The Psychology of Reasoning." By Alfred Bisset. Translated from the second French edition by Adam Gowans White, B.Sc. Chicago: The Open Court Publishing Company.

(a) "Bulletin de l'Académie de Médecine," No. 39; Séance du November 14th, 1899. P. 475.

ledge." The author demonstrates with force and illumination that the fundamental element of the mind is the image, that reasoning is an organisation of images. In proceeding further to elucidate this point, M. Bisset defines perception, adopting the definition of English psychologists, as "the act which takes place when our mind enters into relation with external and present objects." The author is careful to emphasise this truth that in every act of perception the mind constantly adds to the impressions of the senses, thus:—"Everybody knows that we can hear the words of a familiar song clearly, while we are unable to distinguish those of an unknown song, even when both songs are sung by the same voice, a fact which shows the share due to the mind." We might review further, but space forbids. So far, we are on common ground with the author, but there are debatable questions beyond. At the same time we think the book is full of interesting and suggestive reading, and a valuable contribution to psychology.

THE EDINBURGH MEDICAL JOURNAL. (a)

DR. GIBSON has every cause to be satisfied with the success of the *Journal* which he so ably edits. Every one of its six hundred pages is worth reading, and on each the wants of the practitioner of medicine are kept well in view. Not the least valuable papers are the reports on Therapeutics by Dr. Stockman, Dr. Thompson's report on Surgery, and the analytical reports.

Among the clinical records we find Dr. Miller's wonderful "crowbar" case, which, like the "crowbar" case of Dr. Biglow, will probably become classic. Dr. Littlejohn publishes some valuable medico-legal works on suicide which will repay the reading.

Dr. Crum Brown publishes a charming biographical sketch of Dr. John Mayow, that great Cornish student of nature, who foreshadowed the discovery of oxygen, if the isolation of the element be not credited to Robert Hooke, who in his *Micrographia* distinctly pointed to the presence of the element. It is pleasant to note that Hooke proposed Mayow as a Fellow of the Royal Society, and that Beddoes made his works known to his countrymen. All three general practitioners; all three practising medicine as a profession, and all three finding leisure to extend the boundary of the known. They have each written their name on the record of fame.

Space does not allow of our doing more than mentioning the many beautiful illustrations that adds so much to the value of the letterpress.

MORISON'S RELATION OF THE NERVOUS SYSTEM TO DISEASE AND DISORDER IN THE VISCERA. (b)

THIS volume comprises the Morison Lectures delivered before the Royal College of Physicians, Edinburgh in 1897 and 1898. These lectures are usually given on insanity, but in the present instance the author, a relation of the founder, has of necessity, owing to inexperience of mental diseases, to go further afield, and naturally takes up the subject of the nervous system and visceral disease, to which he has devoted some attention. On looking over these lectures one is impressed with the fact that they are largely a repetition of what we already know, and that they are less original than we should expect in Morison Lectures. It certainly must be difficult to find the time to pursue original investigation to such an extent as will furnish a complete set of original lectures, though we are bound to say that Dr. Morison has done some independent work, and procured some excellent illustrations for these lectures. But in our search and anxiety for something new, something to bring us appreciably nearer the goal of our therapeutic expectations, how far onward does this

work bring us? We confess to a feeling of disappointment, for we rise from the perusal of the book with an impression that much has been attempted and little attained. Dr. Morison has done his best to qualify himself for microscopic research, and he is honest in his admissions of failures. He has certainly added to our knowledge of the innervation of the viscera, but the great bulk of this subject is to a large extent a terra incognita, and many of the views entertained on the subject are of uncertain value, or of no value at all, by reason of the conflicting histological results. The last lecture, "On Body and Mind," teaches nothing new, but is rather a compendium of quotations. The author is not careful as to terminology when he speaks of the "profound melancholy of the religious maniac." His appendix on the "Innervation of the Intercranial Vessels" is of more practical importance and value than the greater part of the lectures. Some of the illustrations, of which there are several, are very good.

Medical News.

A Sceptic on Malarial Infection.

A ONE-TIME resident for many years on the West Coast of Africa, communicates to a friend certain criticisms on recent investigations bearing on the spread of malaria which are sufficiently original to deserve notice. He says, "As regards the theories recently propagated, I think—in fact, I feel sure—that Major Ross's ideas are quite wrong. He states that by exterminating the malarial mosquito, the whole malarial question can be settled. To my mind, there was never such an error. Now, when I first came to this tropical part, and was attacked with fever, I am perfectly certain that I never had been bitten by a mosquito of any sort, and slept under a mosquito curtain constantly as a precaution. There is an assistant clerk here who has been bitten and re-bitten; he has lived in places where swamps are the only tracts of surface on which to dwell, yet he has never had the fever, although he has been here three years. I am positive that if you came out, and always used a mosquito curtain, and took every precaution, you would still be liable to malaria. Even supposing the mosquito was one of the causes of transmitting malaria, it is a mere detail, considering there are millions of insects capable of breeding germs equally infectious; yet the doctor proclaims that he has discovered the malaria mosquito, and that it is only a question of the Government exterminating the pest to allow Europeans to live in perfect health in the tropics. How can the Government extirpate millions upon millions of insects that can breed, in swamps, much faster than they can be destroyed? Can you imagine a deputation to inquire into this scourge coming out here to the seat of the trouble, and as soon as it arrives there is a statement made by Dr. Ross, 'I have discovered the malarial mosquito!' The Expedition was back in England again in about a month, and professed to know all about this disagreeable and relentless mosquito! How was it possible to study and find by investigation all concerning the cause of malarial fever in a few weeks? If the deputation was anxious to benefit mankind, it would at least have stopped on the coast six months."

Small-Pox in Basutoland

SMALL-POX is reported to be spreading rapidly in Basutoland, and much difficulty is experienced in enforcing measures having for object to check its spread.

A Fictitious L.S.A.

A PERSON called Holmes was sentenced to three months' imprisonment at the Central Criminal Court last week for having, in giving evidence in a civil case, falsely sworn that he was a licentiate of the Society of Apothecaries, and was duly qualified, whereas it appeared on making enquiry, that the diploma bearing the name of Holmes could not by any possibility have been gained by the defendant. Though the delinquent in this instance received the punishment he deserved, the case shows with what comparative ease the privileges of

(a) "The Edinburgh Medical Journal." Edited by G. A. Gibson, M.D., F.R.C.P. Ed. New Series Vol. VI. Edinburgh and London: Young J. Pentland 1899.

(b) "The Relation of the Nervous System to Disease and Disorder of the Viscera." By Alexander Morison, M.D. Edinburgh and London: Young J. Pentland.

a diploma-holder may be usurped by unscrupulous persons.

Army Medical Nominations.

THE authorities have placed a nomination to a commission in the Royal Army Medical Corps at the disposal of the Catholic University School of Medicine in Ireland.

The British Congress on Tuberculosis.

A MEETING of the Organising Council of the British Congress on Tuberculosis will take place at the rooms of the Royal Medical and Chirurgical Society, 20, Hanover Square, to-morrow (Thursday) at 4 p.m.

Payment of Consulting Surgeons at the Front.

IN answer to a question in Parliament last week the Under-Secretary for War stated that the remuneration in each case is at the rate of £5,000 a year, with free passage to Africa and back.

The Lunacy Bill.

THE Lunacy Bill brought forward by the Lord Chancellor has been read a second time in the House of Lords. It will be remembered that this Bill, which has passed the House on two previous occasions, deals with several points of considerable public importance, one of the most noteworthy being provisions relating to urgency orders which were instituted by the Act of 1890. It is stated that the facilities given by this form of procedure have been abused, and in the interest of the liberty of the subject it is urged that an amendment of the law is desirable.

Isolation Hospitals.

THE Earl of Lichfield's Isolation of Hospitals (Amendment) Bill has been read a second time in the House of Lords, and Lord Harris, on behalf of the Government, promised that it should be brought to the notice of the Local Government Board with the object of submitting to the House of Commons. The object of this Bill is to amend the Isolation Hospitals Act, 1893, with a view to improving the facilities for the provision of sufficient isolation hospital accommodation. The Act of 1893 empowered county councils to provide isolation hospitals and to group districts together for that purpose. The Local Government Board, however, had decided that where a local authority had already provided sufficient hospital accommodation, although it was willing to be included in a hospital district, it could not sell or lease its existing hospital to a hospital committee constituted under the Act of 1893. It is chiefly to remedy this that the Bill has been introduced.

The Dublin Death-rate.

WE are gratified to note that the mortality rate of Dublin, which recently touched 51.1 per 1,000 of the population, has fallen in successive weeks to 29.1. Zymotic deaths are still in excess of average, and chest diseases still more so.

British Medical Benevolent Fund.

THE annual general meeting was held on February 13th, at the residence of Sir William Broadbent, Bart., who occupied the chair. The hon. secretary for finance presented the report of the committee and the treasurer's financial statement for the past year. In the grant department, subscriptions amounting to £892 ls. 9d., and donations amounting to £399 10s. 9d., had been received, and £1,539 10s. had been distributed in sums varying from £5 to £20 to 161 out of 216 applicants. In the annuity department the interest on invested capital had yielded £2,334 ls. 1d., of which £2,203 5s. 10d. had been paid to recipients of the age of sixty and upwards, whilst the capital had been increased by legacies amounting to £1,457 6s. 9d. Ten vacancies caused by death had been filled, and one new annuity created, bringing the number of annuitants up to 109. The accounts of the Fund had been, as usual, audited by a chartered accountant, who drew special attention to the extremely small working expenses, which for the past, as for many years, had been less than five per cent. The death of Sir James Paget, Bart., for many years the honoured president of the Fund, was sympathetically referred to, and Sir Wm. Broadbent unanimously elected to the vacant office, and Dr. Samuel West to that of treasurer. Attention was drawn to the serious

decrease of subscriptions and donations which had occurred during the year, and a hope expressed that fresh effort would be made by all interested in the Fund to remedy the deficiency. The meeting concluded with a vote of thanks to the Chairman, and to the MEDICAL PRESS AND CIRCULAR for the support always given to the charity.

The International Medical Congress, Paris, 1900.

THE Paris Executive of the International Medical Congress give notice that as there has been some misunderstanding about the sectional arrangements every member may join as many sections as he pleases for a single subscription, but that the expense will prevent every member receiving a copy of the whole twenty-four volumes of the proceedings of the Congress. Each member of the Congress will receive therefore in due course:—(i.) A general resumé of the work of the Congress. (ii.) A volume of the Acts of the Congress. (iii.) A volume containing the works of the section to which he chooses to affiliate himself. If a member has joined several sections he will receive the proceedings of the section which he has placed first on his form of application for membership. Members of the Congress who wish to receive the whole set of proceedings should communicate with M. Masson, the Editor, 120, Boulevard St Germain, Paris.

The Irish Official Reports.

THE annual reports of the Irish Local Government Board and of the Registrar-General of births, deaths, and marriages for Ireland, for the year 1899, appeared last week. The former, for this occasion, is a ponderous tome of over 900 pages, crowded up with all the circulars, regulations, and correspondence incident to the new Irish Local Government Board Act. The Registrar-General's report is much in the same form as usual, and we receive it with much regret as the last bequest to Ireland of a useful and meritorious life official Dr. Grimshaw. We shall note both publications next week.

Dublin University.

THE Examiners appointed for the ensuing year are—in Medicine, Dr. Craig, of the Meath Hospital, and Dr. Drury, of Cork Street Hospital; in Surgery, Mr. Heuston, of the Adelaide Hospital; in Midwifery, Dr. Henry Jellett; and in Ophthalmology, Dr. J. B. Story.

School Board Exigencies.

WE have not the slightest wish to offer any hindrance to the school board officials in their endeavours to secure the regular attendance of the scholars, but medical practitioners, on the other hand, are entitled to a certain amount of consideration when called upon to certify the inability of patients to put in an appearance at school. More especially is this the case in regard to hospital medical officers, whose time is far too valuable to be wasted in filling up detailed certificates. We are glad to see that Mr. Franklin, of the Royal Westminster Ophthalmic Hospital, took advantage of a recent opportunity to enter a public protest against what he rightly described as the unreasonable exigencies of the London School Board. It seems that a lad under treatment at the hospital had been summoned for non-attendance, in spite of Mr. Franklin's certificate that the patient was temporarily unable to attend school, apparently on the ground that the officials decline to recognise a certificate in any other than the prescribed form. Under the circumstances the magistrate declined to inflict a fine, and it is to be hoped in future the School Board officials will show themselves less hide-bound in this matter.

Indian Medical Service.

THE following is the official list of candidates for her Majesty's Indian Service who were successful at the Competitive Examination held in London on February 2nd, 1900, and following days, arranged in the order of merit:—

Graham, J. D.	3,640	Oxley, J. C. S.	2,615
Sprawson, C. A.	2,836	Macnee, H. E.	2,560
Cazaly, W. H.	2,828	Lapsley, W.	2,524
Coppinger, W. V.	2,812	Kays, W. D. A.	2,497
Browne, P. A.	2,785	Chalmers, A.	2,459
Spitteler, A.	2,768	Good, J.	2,453
MacKellie, M.	2,651	Houston, W. W.	2,402

FEMALE MEDICAL STUDENTS AND MIXED CLASSES.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—In your "Notices to Correspondents," &c., for this week, referring to female medical students in Paris, you speak of the "ill-bred manifestations of dislike which characterise the conduct of male students in this country when mixed classes are attempted." This sentence is a little too sweeping. I can only speak for my own college and the hospital of my own city, and here I can safely aver that the Cork male students have always treated the female students in that spirit of gentlemanly comradeship which is the perfection of male courtesy. More than that, the appeals to the Board of the South Infirmary which procured the opening of its clinical teaching to women were organised and carried through almost entirely by male students, who did not rest till they had procured full educational advantages for their female comrades whom they had learned to know in the lecture rooms of the Queen's College Cork. How it may have been in other medical schools I cannot say.

I am, Sir, yours truly,

MARCUS HARTAG, D.Sc., M.A., F.L.S.
Cork, February 16th, 1900. Prof. Nat. His.

J. V. R. (Aylesbury).—Alcohol, in the form of whisky or brandy, is recommended as an antidote in carbolic acid poisoning, a treatment which is dealt with editorially in the present issue. Vinegar or dilute acetic acid in equivalent strength is also highly spoken of.

WARNER'S SAFE CURE.

H. H. WARNER, of New York, formerly head of the Safe Cure Company, and a reputed millionaire, is, according to an American contemporary, in the Bankruptcy Court. He owes 2,319,027 dol., and has no assets, but there are thirty-three judgments registered against him.

DR. F. F.—Medical practice in Honduras is reported to be at a low ebb. There are no openings, indeed, we are informed that several practitioners there are anxious to find openings elsewhere.

PUBLIC LAVATORY ACCOMMODATION.

A CORRESPONDENT referring to our comments on the lack of adequate public lavatory accommodation, especially for women, sends us the following effusion:—

Perhaps you're not aware, but I hardly think it fair,
Hence the reason I have taken up my pen,
But at every railway station they charge accommodation
For ladies, but no charge is made for men.

If the "water rate" enforce, charge the men as well, of course,
And so increase the company's large gains,
For surely there are many cannot pay the humble penny,
And so must suffer silently their pains.

A. D.

Meetings of the Societies and Lectures.

WEDNESDAY, FEBRUARY 21st.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—4 p.m. Mr. B. G. A. Moynihan: The Anatomy and Pathology of some Rarer Forms of Hernia. (Arris and Gale Lecture.)

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN (Leicester Square, W.C.).—4.30 p.m. Dr. M. Dockrell: Syphilides. (Post-graduate Course.)

FRIDAY, FEBRUARY 23rd.

CLINICAL SOCIETY OF LONDON (20, Hanover Square, W.).—8.30 p.m. Clinical Evening. The following cases will be shown:—Dr. St. Clair Thompson: Primary Tuberculosis of the Nasal Septum (shown at the Society in October, 1897).—Mr. J. Clarke: A Case of Lateral Curvature of the Spine in an Infant.—Mr. Battle: Patient after Removal of a Portion of Skull for Malignant Disease.—Mr. Battle: Patient after Open Section of Knee-Joint for Irreducible Traumatic Dislocation.—Mr. Kellock: A Case of Achondroplasia.—Dr. C. W. Chapman: Two Cases (father and son) of Congenital Deformity of the Hands, with Absence of Radius in the Child. Other cases will be shown. Patients will be in attendance at 8 p.m.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—4 p.m. Mr. B. G. A. Moynihan: The Anatomy and Pathology of some Rarer Forms of Hernia. (Arris and Gale Lecture.)

Appointments.

AUNGIER, MARK, M.B. Ch.B. Vict., Senior House Surgeon to the Bootle Hospital, Liverpool.

BAYLISS, RICHARD ARTHUR, L.R.C.P. Lond., M.R.C.S., Honorary Medical Officer to the Eastern Dispensary, Bath.

BERRY, H. POOL, M.B. Lond., M.R.C.S., Medical Officer of Health for the Grantham Urban Sanitary District.

BUSHNELL, F., M.D., B.S. Lond., L.R.C.P., D.P.H., M.R.C.S., Pathologist to the South Devon and East Cornwall Hospital.

CHATELIER, EUGENE, J. A., M.B., C.M. Edin., Medical Superintendent to the City Hospital, Birmingham.

CLAY, B. H., M.D., M.R.C.P., L.R.C.S. Edin., Physician to the South Devon and East Cornwall Hospital.

CURRIE, JOHN R., M.A. Edin., B.A. Oxon., M.B., Ch.B. Glasg., Indoor Resident House Surgeon to the Glasgow Maternity Hospital.

HARRIS, S. C., L.F.P.S. Glasg., Medical Officer of Health for the Ely Urban Sanitary District of the Ely Union.

HUTCHINSON, GEORGE ARNOLD, M.R.C.S., L.R.C.P., Assistant Officer to the Glamorgan County Asylum, Bridgend.

JAMES, ALFRED HUGH, M.B., C.M. Edin., House Surgeon at the Aberystwyth Infirmary.

JAMES, W. D., M.R.C.S., Surgeon to the Ecclesall Division of the Sheffield police.

JOHNSON, R. G., L.R.C.P., M.R.C.S., Assistant Medical Officer to the North London Hospital for Consumption, Hainstead.

LINDSAY, Professor J. A., M.A., M.D., M.R.C.P. Lond., Examiner in Medicine, Royal University of Ireland.

LUCY, R. H., F.R.C.S. Eng., M.B., C.M. Edin., Surgeon to the South Devon and East Cornwall Hospital.

MCWERNY, E. J., M.D. Irel., L.R.C.P., D.P.H. Irel., Bacteriologist to the Irish Local Government Board.

PEARSON, JOSEPH, M.B., C.M. Aberd., Surgeon to the Broomhill Division of the Sheffield police.

RENDLE, C. E. RUSSELL, B.A. Oxon., L.R.C.P., M.R.C.S., Assistant Surgeon to the South Devon and East Cornwall Hospital.

STAUNTON-CAHILL, CHARLES, J., L.R.C.P., L.R.C.S. Irel., Junior House Surgeon to the Bootle Hospital, Liverpool.

THOMPSON, Professor, W. H., M.D., F.R.C.S. Eng., an Examiner in Physiology in the Royal University of Ireland.

WEBBER, H. W., M.S., M.D., L.R.C.P., M.R.C.S., Assistant Surgeon to the South Devon and East Cornwall Hospital.

WHIPPLE, CONNELL, L.R.C.P. Lond., M.R.C.S., Surgeon to the South Devon and East Cornwall Hospital.

Vacancies.

Bath General or Royal Mineral Water Hospital, Bath.—Resident Medical Officer, unmarried. Salary £100 per annum, with board and apartments in the hospital.

Burton-on-Trent Infirmary. House Surgeon. Salary £150 for the first year and £170 for the second year, with furnished rooms in the Infirmary, and coals and gas free.

Carmarthen Infirmary.—Resident Medical Officer, unmarried, for twelve months. Salary £100 per annum, with furnished apartments, board, attendance, fire, gas, and washing.

Castlereagh Union.—Trained Infirmary Nurse. Salary £50 per annum, with rations and apartments. Application to M. F. Flanagan, Clerk of the Union.

Consumption Hospital, Ventnor.—Assistant Resident Medical Officer to the Royal National Hospital for Consumption. Salary £100, with board and residence. Immediate application to Dr. Parry. (See Advt.)

County Borough of Stockport.—Medical Officer of Health for five years. Salary £400 per annum, increasing annually by £25 to £500. Apply to the Town Clerk, Town Clerk's Office, Stockport.

Durham County Asylum.—Assistant Medical Officer, unmarried, Salary £140, rising by yearly increments to £160 with board, lodging, washing and attendance. Apply to the Medical Superintendent, Winterton, Ferryhill.

Glasgow Lunacy District Board.—Medical Officer (Assistant) for Woodilee Asylum, to act as Pathologist. Salary £100 per annum, with board, apartments, &c.

Great Northern Central Hospital, Holloway Road, London.—Assistant Anaesthetist for six months. Honorarium at the rate of 10 guineas per annum. (See Advt.)

Mercer's Hospital, Dublin.—Resident Medical Officer. Applications to the Registrar of the Hospital. (See Advt.)

Mercer's Hospital, Dublin.—Vacancy on the Surgical Staff. Applications to the Registrar of the Hospital. (See Advt.)

Queen's College, Cork.—Professorship of Materia Medica. For particulars, of the Under Secretary, Dublin Castle. (See advt.)

Sunderland Infirmary.—House Surgeon. Salary £20, rising £10 annually to £100, with board and residence.

University College of South Wales and Monmouthshire.—Demonstrator and Assistant Lecturer in Anatomy. Salary £120.

Marriages.

GRAYLING—PERKINS.—On February 15th, at Stratford-on-Avon, Arthur Grayling, M.B. Lond., of Forest Hill, S.E., to Nellie, second daughter of W. E. Perkins, Esq., J.P., of Astwood Bank Worcestershire.

HARRATT—NOAD.—On February 15th, at St. Andrew's Church, Fulham, Henry Harratt, M.R.C.S., L.R.C.P., of Elmside, Northam, Sussex, to Winifred Beatrice Innes, second daughter of the late Stephen Innes Noad, of Chigwell Row, Essex.

HEELAS—DENTON.—On February 15th, at Christ Church, Tekenhall Wood, Walter W. Heelas, M.R.C.S., L.R.C.P., of Wolverhampton, to Jessica, daughter of H. E. T. Denton, Esq., J.P., of Tekenhall Wood.

TOMBLESON—LIVINGSTON.—On February 14th, at St. Mary's, Spring Grove, Isleworth, James Bennett Tombleson, M.B., B.Ch. Oxon., Spring Grove, to Eleanor, youngest daughter of James Livingston, Esq., of Claremont House, Isleworth.

Deaths.

CUNDELL.—On February 11th, at his residence, Brunswick House, Kew, George R. Cundell, M.D., J.P.

GIBB.—On January 27th, at Kingston, Jamaica, Robert Chas. Gibb, M.R.C.S., L.R.C.P., aged 49 years.

HEATH.—On February 15th, at Exminster, Devon, aged 34, Alan Jasper Heath, M.D. Lond., Captain in the Indian Medical Service (Bombay), second son of Christopher Heath, F.R.C.S., of London.

HYDE.—On February 8th, Samuel Hyde, M.D., of Lismore House, Buxton, Derbyshire, aged 50 years.

KIDDLE.—On February 9th, at Mongkwa, Burmah, murdered by natives, Major Walter Kiddle, M.D., Royal Army Medical Corps, L.R.G.C.P.

The Medical Press and Circular.

TUBERCULOUS TROCHANTERIC DISEASE.

WITH A REPORT OF FOUR CASES.

By J. BASIL HALL, M.C. Cantab., F.R.C.S.E.,
Visiting Surgeon to the Bradford Union Hospital.

TUBERCULOUS disease of the trochanter of the femur is a comparatively uncommon condition occurring in childhood or early adult life. Strictly speaking the term "disease of the trochanter" is a misnomer, for the deposit of tubercle, so far as my observation goes, is always situated inside the line of junction between the trochanter and the bone, and, therefore, lies in the base of the neck of the femur rather than in the trochanter itself. The tuberculous process seems to be invariably that of sequestrum formation, as described by Cheyne under the name "necrosis with sclerosis." Whether suppuration occurs or not, the condition tends to become quiescent, the tuberculous sequestrum remaining embedded in the bone. Years after, in adult life, vague symptoms develop without any apparent exciting cause, or possibly attributable to some slight injury. So-called chronic rheumatism, aching pain in the hip and thigh with no very evident gross lesion, may continue to perplex both doctor and patient. These symptoms may persist indefinitely, but usually suppuration sooner or later appears, and operation clears up the diagnosis.

During the last few years I have seen five such cases, in each of which the patient had endured more or less pain and discomfort over a prolonged period. In some instances there is no great degree of suffering, but the patient will say that his symptoms are a perpetual nuisance to him. Any little extra exertion brings on pain. His hip and thigh aches at the end of the day, sometimes spoiling his sleep at night. The limb feels stiff first thing on rising in the morning. The uselessness of all treatment worries and depresses him. His objective symptoms are so easily overlooked that his medical man is misled into thinking that he exaggerates his pain. If suppuration has occurred in early life when the sequestrum first formed, the true condition may be suspected, but in some of the cases there is no such clue. There are, however, certain symptoms present which will be found if carefully looked for, and it is with the object of drawing attention to these that I record the following cases.

CASE 1.—Miss L., *æt.* 38, was brought to me in June, 1899. She complained of constantly recurring pain of an aching character in the right thigh which had been troubling her for nearly six years. Slight and often absent when resting, it became very troublesome if she walked about very much or undertook hard work. Dull aching pain generally set in at the end of the day. The limb felt stiff and painful when she first got out of bed in the morning. At

times she feels quite well, at others she is forced to limp.

When four years old she had a severe illness, of which she remembers nothing except that she was carried up and down stairs for six months and had suppuration about the right hip.

Condition when seen.—Healthy-looking woman who walks with a very slight limp in the right leg. When recumbent, the attitude is normal. There is no eversion, nor flexion at the hip-joint. The movements are free except that extreme flexion is a little restrained. Abduction and rotation are painless. There are no enlarged glands. Percussion on the heel is painless. On the outer side of the thigh is an old scar half way between the hip and knee-joint. It is only faintly marked and of small size. The trochanter feels rather larger and more massive than that of the opposite side. This is not due to muscular wasting, as the limbs are equally developed. The enlargement seems to be in an antero-posterior direction, as there is no prominence of the trochanter visible to the eye. The thickening is best felt by grasping the bone with the fingers and thumb in front and behind, whilst the other hand is similarly employed on the other limb. Percussion over the trochanter is painless, but at one spot close to the posterior border doubtful tenderness is elicited on deep pressure. There is no fulness in front of the hip-joint, and no wasting of the gluteal fold.

On July 31st, under ether, the trochanter was exposed by a free vertical incision, and the tissues peeled off it. The surface of the bone appeared healthy. I opened up the cancellous tissue immediately below the insertion of the gluteus medius. The whole trochanter and neck of the femur was excavated by means of a gouge. The bone was soft, spongy and vascular. In the neck of the femur at its base was a yellow non-vascular sequestrum about the size of a horse bean. There was no sign of any pus, but just above the sequestrum was a small circumscribed area of condensed bone, in striking contrast to the somewhat rarefied tissue about it. The whole cavity was packed with iodoform gauze. There was no pain after the first day, and the patient made a rapid recovery.

CASE 2.—J. G., *æt.* 27, was brought to me in February, 1899. He gave the following history. As a child he suffered from an abscess in front of the right thigh, which closed spontaneously after discharging for some months. He thinks that his leg has never been quite right since then, as he has often noticed slight aching pain after much exertion, but until lately it has been insignificant. About three years ago he began to have more marked symptoms, aching pains in the thigh, especially towards the end of the day, and sometimes keeping him awake at night. At the end of twelve months the pain had become so troublesome that he went into hospital. The hip was examined under ether, but he does not know what opinion was arrived at. Twelve months later he was re-admitted, and an incision made over

the trochanter but no bone removed. For the following twelve months he alternately worked and rested in bed. He lost weight, and became pulled down from disturbed sleep and constant pain. Six weeks prior to my seeing him a small swelling appeared in front of the thigh at the site of the old abscess scar from which some matter escaped.

Condition when seen.—Thin, pale, and in poor health; walks with a decided limp. In front of the right thigh, eight inches below the trochanter, is a small opening just internal to the tensor vagina femoris, from which the pus has escaped. The attitude of the limb is normal. The movements of hip, though somewhat restrained, are practically painless. There is no arching of the back on extension, and abduction and rotation are painless. Flexion is limited. There is no shortening of the limb, real or apparent. There are no enlarged glands. The gluteal fold is not obliterated, but the limb generally is somewhat wasted. There are no starting pains at night, but constant aching about the hip and thigh. On comparing the trochanter with that of the opposite side, it feels slightly thicker and more massive, and pressure with the fingers elicits deep tenderness. There is, however, an absence of that fulness in front of the hip-joint which is usually found in hip disease. The thickening of the trochanter is most evident when the bone is grasped as in Case 1. Percussion on the heel is painless.

On February 9th, under ether, the trochanter was exposed by a free vertical incision. On the surface of the bone was a small cloaca blocked by a bud of granulation tissue. A sinus travelled forwards beneath the tensor vagina femoris towards the front of the thigh. The outer wall of bone having been cut away with a chisel, the whole trochanter and base of the neck of the femur was cleanly hollowed out with a gouge. The cancellous tissue was soft, spongy and vascular, showing evident rarefying osteitis. Two small sequestra were found imbedded in the base of the neck of the bone. They were yellowish in colour and contrasted strongly with the vascular tissue in which they lay. Immediately surrounding them was a thin layer of granulation tissue. The cavity was packed as in Case 1. The sinus in front of the thigh was slit up, scraped, and flushed out, and finally stitched. During the first twenty-four hours he had some pain, which was relieved after the first dressing. Four days later he said he had lost all his aching pain, and that for the first time for two years he could sleep soundly. The cavity quickly filled up, and he put on flesh rapidly. He left the surgical home at the end of a month.

The remaining cases I can briefly dismiss with a few words, as they are in most respects similar to those recorded above.

CASE 3.—A man, 35 years of age, who had suffered from aching pain in the right thigh for six years. This was supposed to be due to "chronic rheumatism," and he had undergone various courses of treatment. It had also been suggested that stretching the anterior crural nerve might give relief. Finally he had appealed to a "quack," who had to some extent relieved him by blistering. There was in this case an entire absence of any sign of hip disease, neither could I satisfy myself that the trochanter was enlarged. I proposed, however, that the bone should be explored, and to this he readily agreed. I found and removed a small sequestrum very similar to that in Case 1. The patient was at once relieved of his pain, and is now quite well.

CASE 4.—The patient was a man of middle age with suppuration about the left hip, and a similar case in many respects to Case 2. He had complained for many years of rheumatism in the limb, and had been worse after a fall eighteen months prior to my seeing him. When I first saw him there was decided

thickening of the trochanter and some tenderness on firm pressure, but no signs of suppuration. I advised operation, but he refused to have anything done. Six months later I saw again, when there was present a large abscess beneath the gluteus and tensor vagina femoris. He also had a cavity at the apex of the lung with well-marked symptoms of phthisis. Under these circumstances I decided to aspirate the abscess and inject it with iodoform emulsion in order that, if possible, it might be reduced in size before opening it. This treatment was eminently successful. After eight aspirations and injections the abscess was almost obliterated, having shrunk from a capacity of 22 ozs. to that of 3 ozs. Under chloroform I then exposed the trochanter and removed an old tuberculous sequestrum from the base of the neck of the femur. The case did well, and the patient is now, I believe, in South Africa.

In each of the cases just quoted there seems to have been an osteitis going on round an old tuberculous sequestrum which had remained embedded for many years in the cancellous tissue at the base of the neck of the femur. These sequestra have been described by Cheyne, König, and others.

The history of their formation seems to be that, as a result of a deposit of tubercle there is an inflammatory reaction set up in the neighbourhood; the cancelli becoming filled with young vascular tissue, thickening and new formation of osseous trabeculae occurs. A patch of sclerosed bone results; the tuberculous deposit, extending at the margins, finally caseates. There comes to be, therefore, a small island of sclerosed bone surrounded by caseous material and without blood supply. Should the tuberculous disease cease to spread at the margins, the sequestrum remains, imbedded and the condition lapses into a quiescent state. After a long and indefinite period of quiescence, possibly as a result of some slight injury, a sequestrum may commence to set up a rarefying osteitis around it which will ultimately end in suppuration unless steps be taken to remove it. The cases first quoted may be taken as characteristic types of this recrudescence of the disease, and as such present several features in common.

First, the presence of persistent long-continued aching pain in the thigh, not referred to the knee, aggravated by prolonged standing or exertion, and usually worse at night.

Secondly, the absence of any definite signs of hip disease, particularly pain on abduction and rotation, fulness in front of the joint, and decided muscular wasting and obliteration of the gluteal fold.

Thirdly, some anteroposterior enlargement of the trochanter, possibly very slight, but nearly always present in some degree.

Fourthly, a tender spot in the trochanter (on deep pressure or percussion) is occasionally present.

Lastly, in most of the cases a history of bone disease or symptoms suggestive of it in earlier life, in the affected limb.

The question naturally arises as to whether this condition is a recrudescence of tuberculous disease or merely a simple osteitis set up by the presence of an old sequestrum. In three of the above cases which I have examined I have failed to find the tubercle bacillus, although in all other respects the appearances have been those of tuberculous disease. It is impossible at present to say how long an old tuberculous focus may remain capable of renewing its activity, but there is much evidence to show that recrudescence may occur after very long periods. I have lately seen a case of tuberculous disease of the tarsus which developed after a slight injury. Twenty years previously the patient had been operated upon for disease in the scaphoid and cuneiform bones, and imbedded in these I found, after amputation, an old

sequestrum surrounded by caseous material partially calcified, from which the infection seemed to have occurred.

The operation of excavating the neck of the femur is comparatively simple, easily borne, and quickly recovered from. Care must be taken not to open the joint above nor the medullary canal below. The patient must not be allowed up too soon or fracture may occur. Restoration of function is perfect.

ANTRAL CATARRH AND SUPPURATION. (a)

By J. G. TURNER, F.R.C.S.,
Surgeon to the Dental Hospital, London.

Since the antrum is lined with a mucous membrane continuous with that of the nose and of identical origin, most cases of antral suppuration are cases of muco-purulent catarrh analogous to like trouble in the nose. There is, however, a non-purulent stage, both at the commencement and at the recession of the acuter stage, which is worth recognising. This stage gives rise to symptoms less in degree, but similar to those of the acuter stage, and can be cut short and allowed to get well of itself if the source of trouble be removed and reinforcement of the materies morbi prevented. This makes it important to recognise it. In the receding stage of purulent catarrh the transilluminator shows darkness on the affected side, but I have been unable to satisfy myself that there is appreciable diminution in the early stage.

I will next consider the signs and symptoms of acute and chronic antral suppuration and their causes. I may point out that the pain in either case is due to inflammatory exudation into the tissues themselves and not to pus under pressure. This exudation presses on the nerves, especially the middle and anterior superior dental nerves running in the bony wall of the antrum. Through these nerves the pain may be referred to the supra-orbital nerve at the supra-orbital notch, or to the teeth. This explains why antral pain is so frequently referred to the frontal sinus, though in some cases that sinus itself is diseased and causes pain of itself.

If the ostium becomes blocked either by a plug of muco-pus or by inflammatory swelling of its edges, the pain will be intensified and the pus acts as pus under pressure elsewhere, viz., by boring an exit for itself at the weakest point.

The causes of antral suppuration are to be found in extension from neighbouring sinuses, the frontal and ethmoidal sinuses, and the nose. This latter, especially after fevers or influenza, is far more frequently in trouble; originating round a dead tooth. This may be any tooth, from the first bicuspid, or even canine, to the third molar, the roots of any of which teeth might project into the antrum covered by membrane only. I may mention two cases where teeth, both third molars, started antral suppuration by acting as foreign bodies after being pushed into the antrum in attempts at extraction, one in which suppuration spread from a necrosing tuberosity, and cases where the trouble originated in suppuration of dentigerous or dental cysts, one of the latter being followed by extensive necrosis of the antral walls.

Referring to the use of the transilluminator in diagnosis; the lamp must be placed centrally in the mouth, and both sides compared as to (1) illumination of pupil from within the eye; (2) appreciation of light by patient; (3) amount of light

coming through around lower margin of orbit; (4) amount coming through cheek. This last would be stopped by an ordinary "swollen face," and any solid growth stops light. Stress must be laid on the diagnostic value of a certain amount of swelling, and perhaps capillary injection, of cheek in all cases of chronic antral suppuration. Pain and tenderness alone are not enough—in some cases this is due to turbinate trouble.

The difficulty of treating chronic cases is another point, and I wish to lay emphasis (1) on the condition of the mouth and nose, the mouth especially being surgically a foul cavity in most cases; (2) on the state of the lining membrane of the antrum, which is infected and so infiltrated as to be sometimes over one-third of an inch thick: outside this the bone is chronically inflamed; (3) the shape of the antrum itself with its angular recesses, but especially the cellular nature of the part round the ostium, where cells often extend up on the inner side of the orbit; the frontal sinus may also easily drain into the antrum. Attention, moreover, must be drawn to the danger of infection of the ethmoidal cells from the antrum *via* the cells above mentioned.

I advocate, in chronic cases, that there should be a large opening made in the region of the canine fossa, admitting a finger; that the cavity should be scraped and explored for cellular recesses, swabbed out with pure carbolic, and a big opening made into the inferior meatus of the nose; the cavity packed with iodoform gauze, one end being drawn out through the nostril and the opening into the mouth closed.

After forty-eight hours the plug is to be withdrawn, and if pain or discharge do not occur all may be considered well; but if they do, the communication with the mouth is to be re-opened and the cavity swabbed at intervals with pure carbolic, syringing meanwhile, till pain and discharge cease.

I deprecate the use of drains into the mouth as leaving open a ready avenue of reinfection.

I do not deny that some cases get well with less severe measures, but I have been very impressed with the difficulties of curing a really chronic antral suppuration. Acute cases readily get well once pus is let out and the cavity syringed.

NOTE ON THE USE OF THE VAGINAL PESSARY AS A HELP IN TREATMENT OF UTERINE EROSION.

By ALEXANDER DUKE, F.R.C.P.I., &c.
Cheltenham.

THE hyperæmia co-existing (as a general rule) in cases of erosion of cervix uteri, follicular and otherwise, is certainly conducive to the tardiness of the cure.

By relieving the existing hyperæmia in the first instance by scarification (not puncture), and subsequently by the application of boric acid by vaginal insufflator—the acid being much cleaner and more comfortable to the patient than the glycerine tampon—we are enabled to obtain a much better ultimate result. So far as my experience teaches me the effect of these measures is not lasting enough, and I have had much quicker improvement from the introduction of a well-fitting vulcanite Hodge's pessary in addition. I imagine the splint action of the Hodge, and the support it affords, accelerate the circulation, and so facilitates the healing of the eroded surface.

Indeed, no matter what the true *rationale* may be, I am quite satisfied that the pessary is an important factor in obtaining a more speedy cure, and I have

been surprised to find when observing cases of this nature (where the regular dressings had been applied to os and cervix for a considerable time, with little apparent improvement) in a week or so after introduction of pessary an entirely different appearance of the parts concerned when viewed through speculum.

The prevailing habit with many married women of all classes to resort to various expedients in order to prevent conception, is, in my opinion, a fruitful source of congested uterus, followed by endocervicitis and erosion.

The use of cold water syringing directly after the sexual act (when warm cannot conveniently be obtained) and also the incomplete carrying out of the sexual congress, gives rise to hyperæmia; and this repeated time after time (in ignorance of its mischievous effects) must sooner or later produce the evils spoken of. And it is well for gynecologists to bear this cause in mind when not obtaining the looked-for result in the average time while treating cases of this nature.

I trust that other gynecologists will be able to corroborate my statements after making trial of my suggestions.

THE DILATATIONS AND DIVERTICULA OF THE ŒSOPHAGUS.

By JOHN KNOTT, M.A., M.D., CH B, and Dip.
Stat. Med. (Univ. Dub.); M.R.C.P.I.; M.R.I.A.; &c.

(Continued from page 157.)

IN studying the history and pathology of dilatations and strictures of this rarely-diseased organ, one cannot help being struck with the comparative infrequency of association of widening of the canal above the seat of stenosis. Mackenzie points out that the condition of stricture accompanied by dilatation above the narrowed part is extremely rare, and proceeds to add:—"Among the very large number of cases of cancer of the gullet which I have examined, I have not met with a single example of secondary dilatation." The more limited experience of the present writer has taught him the same lesson. Marchand (*"Néoplasies de l'Œsophage,"* Paris, 1880) collected the accounts of 30 carefully-conducted autopsies, in only one of which dilatation was found above the seat of the (epitheliomatous) neoplasm. In an interesting case recorded by Gradenwitz (1859), the œsophagus of a man who had suffered from dysphagia for 43 years was found dilated above the seat of narrowing, which was situated at the lower end, and presented a considerable degree of thickening. Gouguenheim (1878) published a case of supposed malignant stricture of the œsophagus, in which the walls of the tube above the seat of disease were found both dilated and thinned. In Sir Thomas Watson's classical "*Lectures on the Principles and Practice of Physic,*" a specimen is referred to which presented dilatation above a cancerous stricture of the cardiac orifice of the œsophagus. Bazier (*"Contribution à l'Etude de l'Œsophagisme,"* Paris, 1879) gives the case of a woman who died at the age of ninety of cancer of the stomach, with very pronounced narrowing of the lower six or seven centimètres of the œsophagus, and expansion for some distance above, measuring some centimètres in diameter. Nicoladoni (1877) recorded the case of a little girl of four, who had had the operation of œsophagostomy performed for the relief of increasing dysphagia, which had supervened upon the swallowing of some lye two years before. The result of the operation was fatal, and the middle portion of the tube was found contracted

for about eight centimètres. An irregular expansion of the canal extended for two-and-a-half centimètres above the seat of obstruction. Lindan has described—rather incompletely—a specimen found in the body of a man who had succumbed to the exhaustion produced by increasing dysphagia, which had commenced suddenly about a year before. There was fusiform dilatation of the whole length of the tube, with a rigid constricting band at the lower end. In the middle, where the expansion reached its maximum, the gullet measured 11 centimètres across, and the muscular layers, both circular and longitudinal, were so widely separated as to give the appearance of "a wide-meshed network." Yet the constriction of the cardiac orifice was not so great as to prevent the passage of a sponge probang into the stomach during life.

A peculiarly interesting case of secondary dilatation of the œsophagus was published by West (*Dublin Quart. Jour. of Med. Science*, Feb., 1860), which gained him the credit of being the first writer to establish the probability, if not the absolute certainty, that stenosis of this canal may be of syphilitic origin. Indeed, ever since the publication of his valuable paper on that subject, syphilitic disease of the œsophagus, which had been previously ignored by almost all writers, has received due consideration in every important treatise on syphilis.

Of the two illustrative cases which were first published by Mr. West, the first presented the feature of secondary dilatation above the seat of stricture; and is otherwise so interesting and instructive as to be well worthy of examination in some detail. The patient was a girl, æt. 21, who had for several years suffered from well-marked syphilitic phenomena, such as a scaly cutaneous eruption, sore throat, &c. "She had had gonorrhœa three years ago, but denies having ever had sores or a bubo." At the time of admission into hospital her condition is described as follows:—"She now complains that she cannot swallow anything, and that her food returns during the act of swallowing; about twice a day she is able to swallow without much difficulty. She has no pain, except during deglutition. The throat is very much ulcerated; both tonsils, as well as the fauces and soft palate, being involved; the surface is ash-coloured, with red patches dispersed here and there. She is much emaciated, and very anæmic. Pulse weak; tongue clean; bowels open; urine scanty, but clear and healthy." She was "ordered five grains of iodide of potassium in an ounce of decoction of bark, three times a day, and to use the hydrochloric gargle." Nitrate of silver was afterwards applied to the throat, and mel boracis was used as a gargle.

"This treatment was persevered in till the 28th inst., but without benefit; she got weaker, and the ulceration of the fauces became more extensive, while swallowing was even more difficult; she took scarcely any food, and had no relish for anything. An attempt was made to pass a small œsophageal bougie, but it was ineffectual. . . . Attempts were made every other day to pass a gum-elastic catheter, and, although the stricture could not be penetrated, yet when pressure was made against it for a few minutes, she generally found that she was enabled to swallow better after a few hours." No improvement having occurred from the various forms of treatment which had been adopted, it was determined on the 10th of July to try the effect of a course of mercury, "in spite of her debilitated state, and for some short time, indeed, it seemed to give relief;" a slight amendment was perceived; deglutition was less painful and difficult. On the 6th of August this transient amelioration had ceased. "She had relapsed into her former condition and could not swallow anything for hours together, all attempts at deglutition being attended with the

most painful straining and spasm." She died, exhausted, on the 2nd of September.

On post-mortem examination, it was found that "the upper portion of the œsophagus, for about four inches, was much dilated; its mucous membrane thickened, and marked by spots having the appearance of recent cicatrices. At this distance from the upper end it was suddenly constricted, and terminated in a narrow canal which would barely admit a No. 4 catheter. This constricted portion, which was about two inches and a half in length, was formed by the thickening of the mucous membrane, and by fibrous deposits in the form of bands and bridles, having very much the appearance of an old stricture of the urethra. Below this tract the œsophagus continued perfectly healthy to its termination in the stomach."

In reviewing this case, West thus expresses his grounds for believing that the lesion was of specific origin:—"The fact of stricture of the œsophagus in this case was perfectly patent, and it remains to consider whether any cause, other than that to which I have referred it, can have produced this lesion. Certainly no positive proof of the primary sore can be advanced, but the secondary symptoms extending over a long series of years are distinctly marked; and in how many cases do we find persons in the class of life of this girl denying that they have ever had sores, when their effects are but too plainly visible in the scarred skin, the ulcerated throat, and the carious ossa frontis and tibiæ of the sufferers. Such a sore, no doubt, existed at some period of her career, and its probable site was manifested in the post-mortem examination by a cicatrix in the lower part of the vagina. We have no account of the swallowing of any caustic or irritating fluid, so that we cannot attribute the stricture to that cause. But we find a patient gradually exhibiting the symptoms of well-marked syphilitic cachexia, and also experiencing frequent ulceration of the fauces and pharynx. At first, slight dysphagia alone led to the suspicion that there was narrowing of the œsophageal canal; but, with its persistence and tendency to become worse, the suspicion became augmented, until at last all doubt was removed on an attempt being made to pass a small-sized œsophagus bougie. . . . The presence of numerous recent cicatrices clearly indicated that ulceration had existed in the walls of the œsophagus. The deposit in the submucous tissue was fibrous; it was exactly similar in nature to that which is so well described by Dr. Wilks as characteristic of syphilitic ulceration, and could not under any supposition, be referred either to cancerous or tuberculous degeneration."

In addition to the various causes exemplified by the histories of the cases already given, I would like to call attention to the occurrence of the very rare condition of inflammation of the lining mucous membrane of the gullet as an efficient cause of dilatation. To this, perhaps, as much as, or more than, to the mechanical stretching, may be attributed the origin of the case published by Spengler, in which the patient, during the performance of a hasty meal, had swallowed a hot dumpling, which "stuck fast." According to Zenker, "The view of a primary inflammation is best supported by the case of Stern, where there was an early opportunity for post-mortem examination (a man, twenty years old, who died eight months after the commencement of difficulty in swallowing), and where the microscopical examination of the greatly thickened and hypertrophied mucous membrane, in addition to a partial deficiency in the epithelium, and raising up of the same by pus-cells, discovered a small-celled infiltration through the whole thickness of the mucous membrane, here and there extending down into the muscular layer."

The fact that in cases of inflammation of the lining

membrane of the gullet, the affected part—except when the patient is immediately placed under skilled supervision—is so likely to be further injured by the necessary acts of deglutition, furnishes a prominent factor in the aggravation and prolongation of the inflammatory condition. This may go on till, as occurs in the other hollow viscera, the muscular coats have completely lost their elasticity and contractility, with the inevitable sequel of dilatation—increasing day by day till some mechanical limit has been reached.

In the class of cases in which the modification of structure displays the *saccular* form of dilatation, or, in other words, does not involve the whole circumference of the œsophageal wall, we have the formation of *pouches* or *diverticula*. Such specimens are much more frequently met with than those which I have been hitherto considering. As might be expected, the formation of such pouch or diverticulum is sometimes due to a definite obstruction in the course of the tube, which has the effect of preventing the free passage of the ingesta. The mechanism of the production under such circumstances is easily understood; the food, having been arrested in its downward course, accumulates above the seat of obstruction, and some part of the wall of the canal—weaker or less supported by the surrounding structures than the rest—yields to the continuously applied pressure, just as happens under corresponding circumstances in the rectum and urethra. Some cases have been recorded in which the dilatation of the tube appeared to be the result of the obstruction due to the impaction of a foreign body in the gullet. The most remarkable instance of this kind that I have met with is that recorded by Ludlow ("Medical Observations and Inquiries," Vol. III.), of which the following is a condensed account:—

The patient, a brewer, aged about 60, and reduced to the last degree of emaciation, gave the following history of his own case;—About five years before, he had swallowed a cherry stone, which had stuck in his throat; from which it was expelled three days afterwards during a strong fit of coughing. While the foreign body remained in the pharynx there had been some difficulty of deglutition, the pain which he experienced having been attributed by the patient to the irritation which it had produced in its descent. After its expulsion, he felt for a long time considerable pain in the place where the body had been lodged. About a year after, he began to observe that, an hour or two after a meal, part of the food returned into his mouth unchanged. The quantity which was brought up in this way gradually increased, while the period of time which elapsed between the meal and the occurrence of the regurgitation diminished, till at last the food returned while he was still at table. This now occurred so suddenly, especially when he drank, that he was sometimes nearly suffocated. At last he was unable to swallow more than about four spoonfuls till the aliments returned into the mouth by 'a process similar to that of rumination.' For thirty-six hours before he was seen by Ludlow for the first time, he had been unable to get any nutriment into the stomach. To sustain life under these circumstances, recourse was had to nutrient enemata, but he died thirteen days afterwards in a state of exhaustion.

"On post-mortem examination an immense muscular sac was discovered, lying between the œsophagus and the vertebral column. It was inclined rather to the right of the middle line, and descended into the thorax, but had contracted no adhesions with any of the surrounding structures. A careful dissection showed that this pouch was formed by a dilatation of the posterior part of the pharynx, but the thickness and the structure of the pouch and of the pharynx corresponded so exactly, that it was impossible to say

where the dilatation exactly began. The wall of the œsophagus was very much thinned where it lay in contact with the sac, and the opening by which it communicated with the pharynx was very much narrowed."

In his remarks on this case, Ludlow had no hesitation in expressing his belief that the presence of the cherry stone was the starting-point from which the formation of the sac proceeded. He supposed that, having become arrested in the mucous membrane of the pharynx, and being successively pressed upon by the descending bolus in each act of deglutition, it had at last formed for itself a cavity more or less adapted to its size, and which remained when the stone was rejected, and went on increasing by the presence of the ingesta which remained lodged within it. Nevertheless, the real explanation of the origin of the pouch in this case must still be allowed to remain an open question; and it must continue to be a matter of uncertainty whether the theory of Ludlow be the true one, or whether, indeed, the pharyngeal wall was not the seat of a congenital malformation, slight at first, but gradually increasing in size by the pressure of retained aliments which were there arrested in their descent. The present writer has great difficulty in conceiving how even a cherry-stone could be so retained in a pharynx of normal form during a period of several days. It should, however, be added that, among others, the great pathologist, Rokitsansky, sanctions the hypothesis advanced by Ludlow.

Another very remarkable case of pharyngo-œsophageal pouch has been described by Gianella (cited by Mondière, *Archiv. Gen. de Méd.* XXIV., 411). The patient in this case died at the age of sixty in a state of extreme emaciation, the result of dysphagia; from which he had suffered in a less degree from his youth, but which had for some time before death become so much aggravated that no nutriment could be got into the stomach. Before it took on this severe form he had been able to get down his food by eating slowly, and aiding the descent of each morsel by making pressure on the front of the neck with his hand. At the autopsy, the superior opening of the œsophagus was found narrowed; and, lying between that tube and the vertebral column, a pouch was found extending downwards for a distance of six or seven fingers' breadth. The widest part of this pouch was the opening by which it communicated with the œsophagus. In commenting on the clinical features of this case the writer observes that: "As soon as the aliments arrived at the constricted portion of the œsophagus, instead of following the natural route they descended into this pouch, in which they remained till rejected by a spasmodic contraction of its walls."

A remarkable case of pharyngo-œsophageal pouch has been recorded by Hankel. The patient was a merchant, æt. 54, who died of inanition, the ultimate result of dysphagia which had commenced nine years before:—

"He had on one occasion perceived, while eating, that the morsel was suddenly arrested in the œsophagus. From that time he had always suffered from pain in swallowing. This went on increasing; a portion of the food was rejected after each meal; he was obliged to re-chew it in order to swallow. After a meal, there was always found on each side of the larynx a large tumour, which could be emptied of its contents by pressure; a part passing downwards into the stomach, and a part returning into the mouth.

"On examining the œsophagus after death, a diverticulum of considerable size was found springing from its upper extremity, just beneath the inferior fibres of the pharyngeal constrictor. The opening by which it communicated with the œsophagus was of smaller dimensions than the tube itself; the sac was three inches and nine lines in length, and one

inch and nine lines in breadth; its walls, which were of considerable thickness, were formed by the tunics of the œsophagus: the mucous coat was atrophied."

As Hankel observes, the sac in this case being soon filled by the ingesta at each meal, and having the strong resisting surface of the vertebral column to support it on the posterior aspect, exerted increasing pressure on the œsophagus from behind, till it came by degrees to close it so effectually as to entirely prevent any further passage of food along the tube.

Another very similar case has been placed on record by Coffin (*Bull. de la Soc. Anat.*, 1847). The cause of the dysphagia had remained unexplained during the patient's life. After death a pouch was found springing from the œsophageal wall at its upper end.

A specimen was exhibited to the Pathological Society of London (February 21, 1848) by Mr. H. C. Johnson, in which a pouch large enough to hold a small orange was found to be connected with the œsophagus on its posterior aspect, and on a level with the lower border of the cricoid cartilage. The patient had suffered from dysphagia, for which no cause could be assigned, and about two hours after each meal a considerable portion of the food was ejected in the form of pellets. These had probably been formed in the pouch by the motions caused by the contractions of the tube.

(To be concluded in our next.)

CLINICAL NOTES OF FOUR CASES OF CHRONIC PROSTATITIS. (a)

By DR. H. DELAGRAMMATICA.

Surgeon to St. George's Hospital, Constantinople.

YOU are all aware of the part played by the prostate in cases of inflammation of the genito-urinary organs, especially in cases of blennorrhagia. It is indeed in this gland that we most frequently find the characteristic symptoms of suspected urinary tuberculosis, the cause of the persistence and tenacity of chronic urethritis, and of the various urinary disorders, from simple difficulty of micturition to complete retention of the urine, with its formidable results both immediate and future. According to some authorities it is also the source of troubles of a psychopathic nature, and it is acute inflammation of this organ which, complicating an acute or chronic blennorrhagia, aggravates an otherwise favourable prognosis to such an extent that it may even threaten the life of the patient.

There are very few organs in the human body as vascular as the prostate and as well supplied with lymphatics; and if we bear in mind the numerous anastomoses of its venous plexus, with the hæmorrhoidal, spermatic and vesical plexuses, and especially the plexus of Santorini in front, and the facility with which active congestion or venous stasis may take place in the pelvic organs, we shall readily understand why this gland is so prone to congestion. Its direct connection with the rectum, and more especially with the posterior urethra, renders it, already vulnerable by reason of its anatomical structure, an easy prey to the micro-organisms which flourish in these regions.

It is not surprising, therefore, that a great, possibly an exaggerated, importance should have been accorded to the part it plays in urinary pathogenesis. As late as the end of the last century this gland was thought to be the exclusive seat of blennorrhagia. This error is accounted for by the fact that as gonorrhœal urethritis never causes death

so long as it is free from complications, and because in the fatal cases one occasionally discovered an abscess of the prostate, which had been the starting-point of a diffuse pelvic suppuration. The phlegmon, to which the patient had succumbed, however, was not due to the primary lesion, but to the complication of an urethritis, which had passed unnoticed or had been erroneously regarded as of secondary importance, though, as we now know, it was the initial lesion.

We no longer look upon the prostate as the indispensable and inexhaustible reservoir of the gonorrhœal discharge. Some authors, aware of this fact, have fallen into the opposite error, and hold that this gland, when chronically inflamed, gives rise to the most varied psychical disorders. Quite recently, for instance, Dr. Guizis, of Athens, describes hysterogenic points which he professes to have discovered in the prostate and bladder. Though there may be a few cases of chronic prostatitis, associated with symptoms of neurasthenia or hysteria, there exist a much larger number of cases of prostatitis, which do not exhibit any nervous symptoms, as was the case with the eight patients under my own observation. Besides, if this were true, why should it not hold good for other chronic affections of the prostate?

This is certainly not the case in hypertrophy of the prostate, for example, because this only manifests itself at an advanced age, when psychical troubles are rarely met with. It is much more probable that these neuroses, when they exist coincidentally with a chronic inflammation of the prostate, are quite independent of this inflammation, and it is highly improbable that it alone causes the dreaded genital impotency.

Having disposed of these aspects, chronic prostatitis is none the less a serious disease, not so much in itself as in its being a possible source of auto-infection which may lead to spermato-cystitis, to epididymitis and to cystitis, the consequences whereof must be difficult to foretell, favouring as it does the persistence of the chronic urethritis and consequently introducing a source of contamination, should the purulent secretion contain the gonococcus.

For these reasons and also by reason of the fact that chronic prostatitis is far more frequent than is generally supposed, it occurred to me that a detailed account of four cases out of eight I have recently had under my observation would prove instructive, each of them presenting special points of interest.

CASE I.—P. N. M., at. 40, contracted gonorrhœa at the age of 26. This did not entirely disappear, and two years later he married and infected his wife. From that time they have mutually contaminated each other with gonococci, constantly rejuvenated, so that both of them still suffer from the complaint.

Two years ago the patient experienced difficulty in passing water and consulted a doctor, who, having diagnosed a stricture of the urethra, dilated it to No. 18 (French scale). The resulting irritation caused a slight increase of the running, which once again became yellow. The doctor adopted a combined treatment of alternate irrigations and instillations of nitrate of silver solution. After a few days of this the patient developed acute cystitis with pyuria and hæmaturia, and intense vesical tenesmus. The patient remained in bed for a month, and the cystitis was not cured for at least five months. During this time the patient complained of pains over the left kidney.

Five months ago the patient came to see me; he was pale, feeble, and very anxious about his condition. He passed urine five times a day, but did not get up during the night.

I obtained two samples of urine, the first was muddy and contained grumous material; the second was clear. I filled the bladder with a boracic solution, and on

digital examination, per rectum, I found the prostate, if anything, rather small, flabby, and yielding, showing a slight depression about the middle, without any other anomaly or inequality of consistence. The germinal vesicles were unaffected. I massaged the prostate and again collected a sample of urine. At the bottom of the glass in which I had collected the boracic acid solution numerous whitish corpuscles were to be seen. There was a slight constriction in the bulbo-perineal urethra, and when I reached the prostatic part of the urethra, I was unable to get the bougie any further, the instrument striking an obstacle which was only surmounted by the aid of the finger *per anum*.

Microscopical examination of the grumous material obtained by massage of the prostate gave the following results:—Numerous squamous epithelial cells, leucocytes in abundance; fine refractile granules, and large cocci, probably staphylococci; no gonococci. With these data, diagnosis was easy, viz., stricture of the urethra with posterior urethritis and chronic prostatitis of old standing. By way of treatment I dilated every other day, following this by massage of the prostate and irrigations with perchloride of mercury (1:20,000). After a month's treatment the urethra was dilated to No. 28 of Charrière's plate, and the massaged prostate no longer yielded any secretion.

In order to control the result, and in order also to obtain a more marked action on the posterior urethra, I gave three instillations of perchloride of mercury (1:3,000). After the last instillation, in spite of the violent reaction, the urine obtained on the following day was clear, and further massage of the prostate gave no result. The patient may now be looked upon as cured, but it will certainly not be long before he is reinfected, because his wife persistently refuses to undergo medical treatment.

CASE II.—P. P., at. 38, butcher. Had his first attack of blennorrhagia three years ago, which was cured in two months. He had a second attack eighteen months ago, since which he has suffered from gleet. During the second attack the patient developed a right epididymitis, and suffered from frequent micturition.

The patient consulted me about his gleet (having previously been under the care of several other doctors), which, in spite of the most varied and the most energetic treatment, had not disappeared. He also complained of spermatorrhœa.

The urethra was inflamed, but the bougie (No. 28) was passed without difficulty. On withdrawing the instrument it was covered with a viscid, dirty-yellow material mixed with blood.

Digital examination per rectum revealed an enlarged, not very hard, renitent prostate without any inequality of surface, and insensitive to pressure. I massaged it, and expressed a viscid muco-purulent material, which escaped from the meatus. Thereafter the prostate diminished in size and became flatter.

The pus obtained from the prostate was examined microscopically, and found to contain leucocytes, with a few rounded pavement-like epithelial cells, bacilli and gonococci. My diagnosis in this case was: Chronic prostatitis, or, rather, an abscess in the prostate with general urethritis.

I therefore adopted the treatment of irrigations with potassium permanganate, as well as massage of the prostate. The flow, however, continued for another week, and although the prostate was regularly emptied, it was found full at subsequent examinations. Believing that there was a cavity in the prostate, I tried, by means of straight and bent india rubber sounds, to enter it, but my efforts failed, so I forced the fluid into the cavity of the prostate by pressing on the urethra, and thus interrupting the escape of the fluid while the patient was voiding

the liquid which I had injected into his bladder. This method proved to a certain extent successful, for it brought away some grumous material.

The prostate was subjected to this treatment for twenty days, when it was found to have greatly diminished in volume, but massage continued to express whitish material, which on microscopic examination was found not to contain any gonococci. Irrigation with perchloride of mercury solution failed to arrest the suppuration.

CASE III.—H. K., at. 30, had syphilis three years ago, his first attack of blennorrhagia thirteen years ago, lasting two months; the second attack of blennorrhagia was contracted five years later and lasted four months; a third blennorrhagia five years ago was allowed to cure itself. He had a fourth attack two years ago, followed by gleet, which has persisted ever since. It is highly probable that the patient did not thoroughly recover from the second attack of blennorrhagia, and that the subsequent attacks were recrudescences. The doctor who treated his second attack had already discovered a stricture which only admitted a filiform bougie, and he only partially dilated it. An attack of cystitis complicated by orchitis was the result of this treatment.

The patient complained that for some time past he had had seminal losses mixed with blood. The discharge was most copious when he passed a motion. The meatus was narrow, barely admitting a No. 20 bougie, so I performed meatotomy. The patient passed water drop by drop, and the difficulty of micturition had become more marked since the previous day, when Dr. Mally, of the Austrian Hospital, urgently advised urethotomy.

The urine was very turbid and had an ammoniacal odour; the bladder reached to within a finger's breadth of the umbilicus. In spite of this, micturition was neither frequent nor urgent. The patient passed urine three or four times a day, and never during the night. After several attempts I managed to introduce a No. 4 filiform bougie into the urethra, and leaving it there I advised the patient to pass urine without removing the bougie.

Per rectum the prostate was felt to be of enormous size, and I was quite unable with my finger to make out its limits. Its right lobe was bigger than its left, and it was soft, yielding, and smooth, and did not exhibit any inequality of surface or differences in consistency. Even marked pressure upon it did not give rise to the slightest pain.

The diagnosis was obviously easy, strictures of the urethra (they were multiple, as subsequent examination proved) with chronic prostatitis and also mild chronic cystitis.

Microscopical examination of the urine showed a large number of leucocytes, squamous epithelial cells more or less degenerated; no gonococci, but, on the other hand, numerous bacilli, probably coli bacilli. Subsequent microscopical examination of the urine showed cylindrical epithelial cells and large hammer-shaped casts; these latter, said to be characteristic of follicular prostatitis, besides being indeed casts of the prostate glands. The treatment used was the same as in the first case, and consisted, first, in dilatation, and, when I had arrived at a fairly high number, I washed out the bladder with silver nitrate solution 1-1000, which promptly cured the cystitis.

At the same time I massaged the prostate, and this was followed by the evacuation, *via* the urethra of a large quantity of a sticky fetid pus with a strong odour of ammonia. As the dilatation proceeded, I was enabled to make out three distinct rings in the penile urethra, and an obstruction in the perineal region. I pushed the dilatation, according to the rules laid down by Guyon, to No. 27 without causing any bleeding.

After several examinations I arrived at the conclusion that the prostate of this patient was one large cavity, which fact led me to think of tuberculosis, and consequently to search for the specific bacillus, which, however, was not found. After two months' treatment the prostatitis diminished to half its original volume, the stream of urine became large, and the bladder, the capacity whereof when first seen was 500 grammes, returned to normal, and the urine was clear. I should have liked to continue massage of the prostate simultaneously with the other general methods prescribed, but the patient, after forty-five days' treatment, passed urine with ease, and as it was once more clear, he thought himself cured and did not return.

CASE IV.—L. P., at. 46, has had several mild attacks of blennorrhagia since the age of 20. He had not suffered from cystitis or orchitis until fifteen years ago. About this time the patient had a fall on the perineum, which was followed by hæmaturia, but there was neither retention nor extravasation of urine as the result of this accident.

Owing to the prompt cessation of the hæmaturia, the patient did not at first consult a doctor, but a week later he altered his mind and went to a specialist, who passed a catheter and set up an acute cystitis, which took two months to cure, and then incompletely, since the urine still remained very cloudy. Curiously enough, the same accident happened to the patient again three years later. He was climbing a ladder, and he fell athwart one of the rungs. This was immediately followed by hæmaturia, less copious, however, than the first, and again there was no retention or extravasation of the urine to the bruised region. Frightened by his previous experience, he carefully avoided consulting a doctor. Several months after the accident he began to complain of difficulty of micturition, and along with this the cystitis recurred. Micturition became frequent and urgent, and there was terminal hæmaturia and very turbid urine.

On exploring the urethra, a membranous spasm was distinctly felt, and a No. 24 bougie *à boule* was passed as far as the prostatic region, but no farther. I took a bent gum elastic bougie of the same calibre and passed it into the bladder. A No. 16 straight bougie could not be got in farther than the prostatic region, and it was only by raising it with the aid of the finger in the rectum, that it became possible to pass it into the bladder. There was scarcely any prostate, and I could feel the bougie travelling over the tip of my finger quite readily, through the much thinned walls of the prostate.

Massage of the prostate, after washing out the bladder with boracic acid solution, caused the expulsion of much grumous material.

The patient complained of pain in the region of the left kidney, adding that several months previously he had been very feverish coincidently with each fresh attack of this pain, and this had been followed by the passage of a very purulent urine.

Microscopical examination showed the presence of epithelial cells from the bladder, of leucocytes, and of bacilli exhibiting the characteristic form and colour of coli bacilli.

The patient is still under observation, an intercurrent affection having prevented him from following the prescribed treatment. I propose to perform cystoscopy if the urine after the treatment directed to the relief of the cystitis does not clear up, to find out whether the pus comes from the ureters.

The most interesting point is the collapse of the prostate almost in its entirety, this having taken place insidiously, without any inflammatory reaction, and the resulting deformity of the canal.

Clinical Records.

CASE OF RADICAL CURE OF HERNIA.

By PERCY G. LODGE,
Bradford, Yorks.

MR. T., *æt.* 40, architect, of Leeds, had a swelling as large as an ordinary orange in left inguinal region, the testicle undescended on the same side. His doctor, Dr. Higgins, recommended operation. The duration of the epiplocele was about six years.

On October 15th, at patient's house, the preparations being already completed beforehand, I made an incision of four inches afterwards increasing it to eight, over the swelling. The various layers were carefully picked up and divided on a director until the sac was reached and carefully opened. Only omentum adherent at various points was exposed within. These were gently separated and an attempt made at its return within the body, this, however, proved impossible, so we decided on its removal. The omentum was opened out and snipped across with blunt-pointed scissors, catching up the vessels with catch forceps as each was divided. The weight of omentum thus removed was over one pound and a half. The forceps were now tied off and the free edge hemmed with a running catgut suture. Finally, the stump was returned. The front wall of the canal during this time was lying open. The next step taken was to examine the testicle; it was dissected up with the sac, and its removal was now seen to be necessary; it was very soft and much atrophied. Accordingly the cord and sac were divided at just below the level of the internal ring, the vessels in the stump were tied, the sac previously separated was closed by ligature and stitched to the stump. The muscular structures of the abdominal wall were now securely stitched to Poupart's ligament so as entirely to close in the abdominal wall. A continuous suture closed up the sponeurosis of the external oblique, and there only remained a few sutures for the skin. Afterwards suitable dressings were applied, and the limb immobilised by a piece of stout poro-plastic felt down the front of the body and thigh. Dr. Higgins tells me that the further progress of the case was for the most part uneventful, beyond one or two stitch-abscesses at the lowest part of the incision, which eventually did well. The cure is most complete. The patient is now well and able to get about quite easily. My thanks are due to Drs. Crowther and Higgins for their valuable assistance.

Transactions of Societies.

CLINICAL SOCIETY OF LONDON.

MEETING HELD FRIDAY, FEBRUARY 23RD, 1900.

DR. LEONARD SEDGWICK, Vice-President, in the Chair.

CLINICAL EVENING.

PRIMARY TUBERCULOSIS OF THE NASAL SEPTUM.

DR. ST. CLAIR THOMSON presented a young woman who had already been shown to the Society in October, 1897. In July, 1896, a growth the size of a filbert was removed from the right side of the nasal septum, diagnosed as tuberculous though no bacilli were present. Three months later the base of the growth broke through the septum. She had active local treatment and three injections of Koch's tuberculin, to which she reacted. When recently examined it was seen that the perforation had increased in size, but the condition in other respects was better. Sections showed giant cells and caseation but no bacilli. The treatment was painting with Mandl's solution of iodine and iodide of potassium, and, later on, guaiacol and olive oil.

MR. BARKER referred to a case of very extensive tuberculosis of the nose which had involved the lacrymal sac and had perforated the soft palate. Treatment by painting with the perchloride of iron and dusting with iodoform had proved very successful.

DR. KIDD agreed that the lesion was probably tuberculous, although the microscopical appearances were not conclusive.

A CASE OF LATERAL CURVATURE OF THE SPINE IN AN INFANT.

MR. JACKSON CLARKE showed an infant, *æt.* 17 months, with well-marked scoliosis, probably due to rickets. Deformity was first observed at 13 months. In addition to ordinary general treatment he insisted upon the importance of daily manipulations and the use of an effective instrument, such as Chance's splint, and he pointed out that poroplastic and other corsets and recumbency caused loss of muscular strength and general physiological depression, and were therefore to be avoided.

OPERATION FOR IRREDUCIBLE TRAUMATIC DISLOCATION OF THE KNEE.

MR. BATTLE showed a woman, *æt.* 50, who, as the result of a severe twist of the left knee, had marked displacement of the knee-joint, the patella being displaced outwards and fixed. The mobility of the joint pointed to rupture of the internal lateral and crucial ligaments. Manipulations having failed he opened the joint by a transverse incision, dividing the ligamentum patellæ. The patella was found to be fixed by a thick muscular band, torn from the inner condyle, through which it had slipped, and it was freed and replaced. On opening the joint freely the anterior crucial ligament was seen to be torn away from the femur, and the posterior crucial ligament lacerated. These were sutured and the internal lateral ligament repaired. The case did well except for a little suppuration on the inner side of the wound, and the patient could now walk normally.

A CASE OF ACHONDROPLASIA.

MR. KELLOCK showed a boy, *æt.* 4½ years, the second of a family of four, the other children being normal. Was born easily at term, but had a queer shape. Breast-fed until ten months. Began to crawl at six months, but did not walk until two years. Was only 30½ inches in height, the deficiency bearing on the lower limbs, the bones whereof were shorter than usual, and the epiphyses abnormally large. The head had a large vault and a narrow base, and the patient presented the usual lordosis, prominent abdomen, genu retrorsum, waddling gait, and a peculiar manner of raising himself, all features characteristic of such cases. The child was intelligent, and had good general health.

TWO CASES OF CONGENITAL DEFORMITY OF HANDS (FATHER AND SON).

DR. CHAPMAN showed father and son presenting a peculiar deformity of the hands, with, in the child, absence of radius. The right hand of the father exhibited the peculiarity in respect of the three phalanges that the second was flexed at a right angle on the first and the third on the second. The thenar eminence was almost entirely absent and abduction and adduction non-existent. In the left hand the terminal portion, representing the thumb, was united for two-thirds of its extent with the index finger, and there was a wide cleft between the first and second fingers. The man used the index finger like a thumb and the hand could be used for most purposes. The son, an intelligent boy of three, exhibited the following deformities:—On the right the thumb at its terminal part resembled a finger. It had three phalanges, the second and third being permanently flexed on the first. On the left there was an entire absence of the radius with a club hand of the radiopalmar variety.

A CASE OF ASTHENIC BULBAR PARALYSIS.

DR. GUTHRIE showed a girl, *æt.* 23, formerly a waitress, working very long hours. Two years ago she noticed some difficulty in articulation, worse when fatigued. Last July swallowing began to be difficult for both solids and liquids, and then she became unable to close her eyes properly. These symptoms had gradually increased until first seen a month ago, when there was weakness of the orbicular muscles of the eyes and mouth and of the soft palate. He regarded it as a case of the

kind described by Strumpel as asthenic bulbar paralysis. The condition had improved under rest and treatment.

CASE OF PARALYSIS OF CRANIAL NERVES.

Dr. BEEVOR showed a case of "Paralysis of the 7th, 8th, 9th, 10th, and 11th Cranial Nerves on the Left side," in a woman, *æt.* 32. No family history. Six years ago she contracted a primary specific sore, followed by sore throat, hair falling off, and rash over chest. Since then had two children, one born blind, the other became so soon, and a miscarriage. Nine years ago blow on the left ear, with deafness and noises ever since. *Present Illness.*—Two-and-a-half years attended for twitching of left side of tongue and the facial paralysis and deafness in the ear. Three months neuralgic pains in left temple. Six weeks voice hoarse and difficulty in swallowing. Three weeks discharge of blood from left ear. *At present.*—Right optic neuritis, not complete. Absolute deafness of the left ear to aerial and osseous conduction. Polypus Taste lost front and back, on left side of tongue. Left facial completely paralysed, including platysma. Paralysis of palate on left side, so that would draw to right on phonation and also on reflex stimulation. Difficulty in swallowing. On posterior wall of pharynx left side, some anæsthesia. Complete paralysis of left inferior laryngeal nerve, with the left vocal cord in the cadaveric position. Pulse frequency not increased. Tongue, left side wasted with fibrillar tremor, goes to left when protruded, cannot put tip so well into left as right cheek. Left sterno-mastoid, complete atrophy and paralysis. Left trapezius atrophied and paralysed with exception of fibres, arising from sixth cervical to second dorsal spines, which contract faintly to volition and faradism. Rest of muscles do not react to faradism. Sterno-hyoid and omo-hyoid contract well. Severe neuralgic pain in the ear and temple. Probably syphilitic meningitis affecting nerves of medulla.

A CASE OF UNILATERAL LESION OF THE PONS.

Dr. COLLIER, for Dr. Hughlings Jackson, showed a man, *æt.* 40, with no pathological history, whose illness began gradually with giddiness, deafness of left ear, alteration of speech, difficulty in guiding left arm and diplopia, difficulty of swallowing and mastication, and loss of feeling on the left side of the face. No headache, vomiting or dysuria. The optic discs were pale, and there was paralysis of the fifth, sixth, seventh, and eighth cranial nerves on the left side, with weakness of the ninth, tenth, and eleventh. He held his head in the right cerebellar position. There was slight spasticity of the right arm and leg, and the speech resembled that often met with in cases of disseminated sclerosis.

CASE OF MACROGLOSSIA AFTER TWO OPERATIONS.

Mr. BARKER showed a girl who first came to him thirteen years ago with macroglossia, when he removed wedge-shaped portion of the organ bringing the side angles together. The case is recorded in Vol. 41 of the *Pathological Transactions*. She had returned last year with recurrence, and the growth this time being in the direction of the hard palate, and on this occasion he had removed a wedge-shaped piece in a horizontal plane, bringing the upper and lower flaps together. Sections of the first growth showed a preponderance of lymphoangiomatous tissue, but the latter was more of a nevoid character.

THREE SURGICAL CASES.

Mr. F. C. WALLIS showed a child, *æt.* 3, with tuberculous disease of the knee which he had treated by division of the patella, free exposure of the joint, removal of the affected synovial membrane and swabbing with pure carbolic. The child is now able to walk, and has limited movement of the joint. He referred to two other cases similarly treated with equally good results.

He also showed a case of acute infective osteomyelitis in a child, *æt.* 12, with necrosis of the whole of the shaft of the humerus. A large sequestrum was removed (shown). The arm, which was previously useless, is now rapidly regaining power.

Case 3 was one of osteitis and periosteitis in a child, *æt.* 11, which he treated by cutting down on the tibia,

elevating the periosteum, and cutting a deep groove through both the epiphysis and the diaphyses. Since the operation the pain had disappeared and the child could stand. The case was originally thought to be tuberculous.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF MEDICINE.

MEETING HELD FRIDAY, JANUARY 26TH, 1900.

The President, Dr. J. W. MOORE, in the Chair.

Dr. R. TRAVERS SMITH exhibited a case of ataxic paraplegia and a case of amyotrophic lateral sclerosis.

BRONCHOTOMY IN CROUP: DIPHTHERIA AND ALLIED MEDICAL CONDITIONS.

Mr. H. GRAY CROLY detailed the symptoms of a case of diphtheritic inflammation of the larynx and trachea in a child, *æt.* 2, admitted recently into the City of Dublin Hospital under the care of Sir George Duffey, senior physician to the hospital. The child at 10 p.m. was in a most critical condition—urgent dyspnoea, lips bluish, signs of collapse. With much difficulty the fauces were examined. The tonsils were considerably swollen, and there was some evidence of a whitish patch on one side. High tracheotomy was performed; the child got immediate relief, and fell into a peaceful sleep. At 4 o'clock a.m. the little patient became very restless, gradually got worse, and died within twelve hours of the operation. The larynx and trachea were removed in a few hours, but no further examination was made. The larynx and trachea, with the silver tube *in situ*, were exhibited. The epiglottis was thickened and hard; the folds at the entrance of the larynx considerably thickened. On opening the windpipe a bluish false membrane easily detached was found at one side. Mr. Croly exhibited some fine specimens of membranous croup from the Museum of the Royal College of Surgeons. He also showed some trachea tubes, and made some practical suggestions on the shape of the tube with a view of preventing irritation, and advocated strongly the high operation, which is so much easier and safer than the deep operation.

The PRESIDENT said there were three affections of the larynx attended with evidence of obstruction to the breathing. First, laryngismus stridulus, a purely spasmodic affection. Then, a very rare condition, croupous laryngitis, analogous to croupous or plastic bronchitis. To the third condition, diphtheria of the larynx, they must refer most of the cases formerly described as croup. His experience was that two micro-organisms were concerned in the production of diphtheria—namely, the Klebs-Löffler bacillus and the streptococcus; and in some recent cases in the Meath Hospital of what was undoubtedly diphtheria, the former micro-organism was conspicuous by its absence. That these were diphtheria, and of a malignant type, was proved by the fact that there were three fatal cases out of six. Four of these cases were examined bacteriologically, but in not one was there a culture of the Klebs-Löffler bacillus obtained, but in two of them Oertel's streptococcus was found. He presumed that what Trousseau meant by malignant diphtheria was diphtheria after the development of the constitutional symptoms as distinguished from the merely local disease.

Dr. E. H. TAYLOR did not agree with Treves' statement that there was no danger in cutting the isthmus, for on injecting the gland large vessels were found crossing in the isthmus.

Professor E. H. BENNETT did not concur in Mr. Croly's recommendation of taking out a piece of the trachea, because he knew of a man of great skill, now dead, who in taking out a piece of the trachea took out a portion of the innominate artery. He preferred a straight simple incision in the middle line.

Dr. O'CARROLL gave an analysis of cases in the Hardwicke Hospital. They had 101 cases labelled diphtheria in the last year. In 47 of these the Klebs-Löffler bacillus

was found, in 46 it was not identified, and in the remaining 8 cases, for some reason or other, no examination was made. There were 17 tracheotomies done, with 11 deaths and 6 recoveries. The cases below two years of age were not successful when operated on, this fact bearing out Mr. Croly's observation. Dyspnea in long-standing cases was due to the development of bronchopneumonia and obstruction of the smaller tubes. Only one or two of those cases in which no Klebs-Löffler bacillus was found died, and they were cases of malignant local gangrenous sore throat, possibly diphtheritic or post-diphtheritic. In those, also, there were other infections, streptococcus and straphylococcus. Tracheotomy was useful in giving the patient a longer time to avail himself of the ordinary aids to recovery. In the Hardwicke Hospital they were fond of large doses of the antitoxin, giving to patients three years old at least 3,000 units. Calomel fumigations and swabbing out of the throat locally are also adopted.

Dr. PARSONS said that the expression "membranous croup" was a most unfortunate one, as they did not know exactly what the older writers meant by it. It seemed to him a pity to place the cases in the Meath Hospital, in which no Klebs-Löffler bacillus was found, under the name of diphtheria. The term diphtheria should be limited to Klebs-Löffler cases, for if they included under this heading every disease with a false membrane, they would not be able to compare results. He took it that the anti-diphtheria serum was useless in streptococcus cases, for what they wanted then was anti-streptococcus serum, which had not yet been proved satisfactory. There was nothing to be learned from past records of surgery since they did not know exactly what disease was meant, and also there was no antitoxin to use then.

Sir George Duffey, Dr. Knott, and Mr. G. J. Johnston also spoke, and Mr. Croly replied.

The Section then adjourned.

THE BRITISH BALNEOLOGICAL AND CLIMATOLOGICAL SOCIETY.

MEETING HELD AT NO. 20, HANOVER SQUARE, THURSDAY, JANUARY 26TH, 1900.

DR. IVOR MURRAY (Scarborough), President, in the Chair.

THE TREATMENT OF DISEASES OF THE NERVOUS SYSTEM AND NERVOUS AFFECTIONS BY BATHS AND CLIMATE.

In opening a discussion on this subject, Dr. HARRY CAMPBELL remarked upon the beneficial influence of change of air which he connected with the wandering habits of primitive man. The open-air treatment he contended was beneficial in other diseases than phthisis, notably in nervous diseases. He referred to the large part which toxins play in neuropathology, and to the potent influence of climate and baths on metabolism, and therefore on the toxicity of the blood. It was often advisable to put nervous patients through a preliminary treatment before sending them away, otherwise they might not benefit by the change. Dr. Campbell held that British Health Resorts were not so well equipped for the treatment of neurasthenia as some of the Continental ones. He referred to the advantage of reducing high arterial tension in some nervous affections, and concluded by inviting discussion regarding the climatic and balneological treatment of sleeplessness, neuralgia, Graves' disease, epilepsy, chronic alcoholism, and morphinomania.

Dr. SYMES THOMPSON spoke of the importance of change of environment in functional and organic nervous diseases. Besides alteration of climate, diet, avocation, &c., we could secure at our spas and health resorts the watchful supervision of trained physicians, with special experience in the application of mineral waters, baths, hydropathic methods, diet, and exercise. He contrasted the effects of Alpine health resorts for those capable of enjoying vigorous exercise with Egypt for persons with organic diseases for whom the restful life on the Nile was often strikingly beneficial.

Dr. RISIEN RUSSELL, in illustration of the good to be obtained from baths in the treatment of chronic organic affections of the nervous system, instanced their ameliorating effect on certain troublesome symptoms in certain diseases of the spinal cord. Peripheral neuritis was chosen to exemplify the beneficial effects of this mode of treatment in certain acute affections of the nervous system, but he insisted on the deleterious consequences to be expected from the indiscriminate use of baths in many acute organic diseases. On turning to the consideration of functional affections, neurasthenia was selected as an example of an affection, the different varieties of which called for very different forms of bath treatment. The neurasthenic who requires stimulating may derive much good from the cold bath properly given while another class of neurasthenic may be injuriously affected by this measure, and may, nevertheless, obtain benefit from the indifferent bath. In conclusion, he alluded to the advantage of baths as a means of administering general faradism or galvanism, and referred to the different effects produced by the two forms of bath.

Dr. KINGSCOTE remarked that high altitudes tend to a high tension pulse, and are therefore unsuitable to hyperæsthetic conditions such as neuralgia and inflammatory states whereas anæsthetic conditions benefit largely, always provided that the heart be sound. For instance, severe neuralgia often subsides immediately on the patient seeking a lower level, whereas the pains due to atrophied muscles often disappear equally quickly on seeking a higher level. Further, toxicity is apt to be reduced owing to increased elimination at high elevations.

Dr. BEZLY THORNE agreed that auto-intoxication exercises a dominant influence in the causation of the greater part of nerve diseases. The "bracing" quality of a climate, he urged, depended more upon the hygrometric condition of the atmosphere than on its mere temperature. A moderate altitude in an open situation, as at Malvern, Buxton, and in parts of Yorkshire, may be far richer in health-restoring conditions than an Alpine height of, say, 3,000 ft., surrounded by mountains. The influence of climate and baths on insomnia depended, he thought, on whether they raised or lowered intra-arterial pressure. In certain cases in which baths increased arterial tension insomnia was aggravated and *vice versa*. Grave's disease being mainly the result of auto-intoxication, suitably administered baths exercised a powerful influence for good. Their good effects in epilepsy are likewise very striking.

Dr. KARL GRUBE, of Neuenahr, said that he had often been struck by the small attention that had been paid in England to the balneological treatment of nervous diseases. Neither in the handbooks on nervous diseases nor in the books of balneotherapeutics sufficient mention is made of this valuable form of treatment. This to him seemed all the more remarkable as some forms of nervous diseases which are particularly benefited by bath treatment appeared to be very frequent in this country—for instance, neuritis. Baths were very effective in the treatment of neuritis, especially when there was much pain. Neither very hot nor cold baths seem to do much good in nervous diseases; on the contrary they very often do harm. Indifferent baths, *i.e.*, baths of a temperature of about blood heat, are most beneficial.

Dr. FLETCHER BEACH said that two cases, one of lateral sclerosis and one of tabes, which had been under his care had been much benefited by residence at the sea-side. Open-air treatment was especially desirable for mental as well as for nervous diseases, and in all asylums patients were given as much open air as possible. In some cases of neurasthenia rest was desirable. The absence of a complete system of baths attached to hospitals was a defect.

Dr. FORTESCUE FOX (Strathpeffer Spa) remarked that baths were of advantage, not in advanced disease (sclerosis) but in the early stages of such disease, and in many nervous disorders, especially those manifested by irritability and exhaustion. A sedative climate and sedative baths, such as those of Schlangenbad, &c., at or a little below blood heat, were valuable in such cases. He also referred to the good effect of douche and peat

baths in peripheral neuritis and in non-inflammatory sciatica.

Dr. LEON (Sidmouth) remarked that, with regard to the effect of climate, high altitude and a dry bracing air had a vaso-constrictor influence; the opposite applied to a low-lying humid situation, arterioles were dilated and the blood pressure low. Sleeplessness was common at high altitudes, and vasodilator drugs also gave good results in sleeplessness and restlessness of old age. With regard to bath treatment, valuable results were obtained in the treatment of local neuralgia, various post-influenzal neuroses, *e.g.*, tachycardia. Sciatica was often much relieved by douches. In the treatment of neurasthenia, change was an important aid, the over-worked should be given rest; the neurotic and invalid never well enough to go out should be stimulated by baths suitably graduated with massage and exercises, and could often be induced to throw off the neurasthenic habit.

France.

[FROM OUR OWN CORRESPONDENT.]

PARIS, February 24th, 1900.

THE MEASLES MORTALITY IN PARIS.

At the meeting of the Académie de Médecine. M. Vallin read a paper in which he drew attention to the progressive increase in the number of deaths caused by measles in Paris. Statistics showed that measles at present was the most deadly of all infectious maladies. Whilst the number of deaths due to typhoid fever, diphtheria, whooping-cough, scarlatina, &c., was declining for the last five years that of the victims of measles was constantly increasing. That difference might be attributed to great attention to disinfection of those diseases of which the declaration was obligatory. If measles was not inscribed among these maladies, it was because it was believed that the virulence of the morbid germ being transitory, disinfection was applied too late to be of any use. But it should be observed that the contagion of measles did not lose its virulence as quickly as it was supposed, and, on the other hand, the patient did not die of the measles itself, but nearly always of the complications, of which the most frequent was bronchopneumonia. This last complication was due to the presence of the streptococcus, and it was that microbe which rendered so dangerous the admission of a patient suffering from measles to ill-kept children's wards. The micro-organism was so much the more to be dreaded that in the malady in question the mucous membrane of the air passages had lost their protecting epithelium, rendering more easy the inoculation of all the pathogenic germs suspended in the air—tubercle, diphtheria, infectious pneumonia, &c. Consequently, if disinfection was useless against the measles properly called, the same could not be said of its complications. The speaker concluded by saying that it was dangerous to allow the public to believe any longer that there were no precautions to be taken against the contagion of the measles, and esteemed that that affection should be classed with the list of contagious disorders of which the declaration was obligatory.

LATENT ANEURISM.

Prof. Huchard communicated the case of a patient in whom aneurism of the aorta remained ignored for several years. The aneurism was seated in the thoracic portion of the aorta, and gave rise to sharp intercostal pain which obliged the patient to walk bent in two, and persisted in the horizontal as well as in the upright position.

The pain, which occupied the base of the thorax, and the ninth and tenth intercostal spaces on the left side, was attributed by several doctors to intercostal neuralgia, and treated as such without the slightest relief.

The characters of the pain on the one hand and syphilitic antecedents of the patient on the other, suggested to Mr. Huchard that the case was one of aneurism of the aorta, situated in the region designed by him under the name of *latent zone*. An attentive examination of the thorax showed, in fact, the existence in that zone of abnormal pulsation, with a slight expansive movement, which left no doubt on the presence of an aneurismal tumour of the aorta. Examination by the radiograph confirmed the diagnosis.

M. Rendu said that some time ago he attended an officer who suffered for five years previously from intense intercostal pain, and in whom the respiratory murmur was completely abolished on the left side. Although no physical sign of an aneurism existed, he pronounced the case to be an aneurism of the thoracic aorta pressing on the left bronchus. Some time afterwards the patient died suddenly in going upstairs, which fact seemed to prove that his diagnosis was exact. He knew, on the other hand, a woman in whom the intercostal pains, which had resisted all the means habitually employed against neuralgia, yielded to the influence of iodide of potassium. He believed consequently that it was another case of aneurism of the aorta.

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, February 24th, 1900.

At the meeting of the Medical Society of the 7th inst., Hr. Cassel read a paper on

NEPHRITIS OF YOUNG CHILDREN.

During the past few years he had observed a series of symptoms in nine young children from six weeks old to two-and-a-half years. Without precedent scarlatina, and with a sound heart, the children had œdema, three of them with ascites, whilst no albumen was present during any part of the illness, nor any trace of sediment or casts. Ætiologically the cases were not all alike. In two of them there was said to have been a rash 14 days before. The speaker suspected this was varicella from the description. In some of the children the spots were still visible. In one of the children measles came out after the œdema without influencing the course of the latter. In four of the children disturbances of digestion preceded the swelling, in one case no ætiology could be discovered. Scarlet fever could be absolutely excluded, as also lues and tubercle. Two of the children were withdrawn from treatment in from 10 to 12 days, four recovered, and three died. The urine carefully collected and examined was clean, colourless, slightly acid, and of low specific gravity, and as said contained no albumen. The quantity varied considerably. Two autopsies made explained the nature and causes of the symptoms. The first in 1897 was made on a child of six weeks, nourished artificially. It suffered from acute intestinal catarrh, with vomiting of a green watery fluid, there was intertrigo on the nates, after a week's treatment some improvement took place, but when cow's milk was given for a few weeks, the child became worn with obstinate bron-

chial catarrh and excessive paleness. After some weeks the œdema got worse, and it finally died of hypostatic pneumonia. There were no uræmic convulsions. There was but little fluid in the abdomen, a teaspoonful in the pericardium, the heart not enlarged, musculature and valves normal. The kidneys were not enlarged, the capsule was softened, the surface quite smooth, the consistence very soft. There was swelling of the epithelium, and partly degeneration, the canaliculi dilated to five or six times the normal, plugged with detritus, and cells of various kinds, in part with epithelial cells from the canaliculi in part with coloured nuclei and nucleoli, and necrotic renal epithelium. The second autopsy was made on an artificially fed child of seven weeks, who had presented similar symptoms of intestinal derangement, the heart was not enlarged, there were some hepatised spots in the lungs, the solitary follicles with colon were swollen. The spleen was very red; the capsule could be stripped off. The medulla of the kidney reddened, the glomerules rich in nuclei, exudation in certain spots, with only rare small celled patches, which were scattered through the cortex, bloodvessels filled with red blood corpuscles. It was evident the kidneys had undergone considerable alteration of structure.

As regarded the literature of the subject, Phillips, of Berlin, in 1840 described an epidemic of scarlatina in which he saw at least one hundred cases of œdema, in sixty of which there was absence of albumen in the urine. An Italian physician, Henoch (1870); and Litten (1873) had described cases, and after them a large number of observations had been made. Henoch explained œdema after acute and subacute intestinal catarrh by failing energy of the heart, and thrombosis of large veins, but pointed out that nephritis must not be lost sight of. Filatow held that these forms of anasarca had nothing in common with nephritis, as there were no albuminuria and no uræmia. The capillaries of the skin were damaged by the circulatory portion, and the nerve centres of the heart participated in the evil results. The speaker thought these views, however, were theoretical, whilst his own preparations pointed to the firm basis of fact, so that in such cases he should always keep the possibility of nephritis in mind.

Hr. Senator thought Cassel's communication very interesting, as it disposed of the prevalent view that œdema was caused by the loss of albumen. Possibly in these cases the canaliculi were blocked in places only, so that the urine came from healthy parts. Any other explanation could scarcely be drawn.

Hr. Israel had seen a case in an adult where for months there was no albuminuria, although there was double nephritis with extensive necrosis and fatty degeneration of the epithelium.

Hr. Bajinsky remarked that dropsy in badly-nourished children was not so rare and was not pathological, and even when autopsies were made, what appeared at first to be nephritis might only be desquamation of the tubules, with excessive casting off of the epithelial layers.

Hr. Heubner did not doubt that Cassel's preparations were really nephritic. The daily quantity of urine passed was very important. In hospitals, when the whole quantity passed could be examined, albumen was always found.

Hr. Cassel remarked, in reply, that the salient point was whether in cases of cachectic dropsy, the kidneys

were found healthy at the autopsy. His preparations were undoubtedly nephritic, and although the daily total of urine was not collected, the absence of morphological constituents was remarkable.

At the Hufeland Society, Hr. Liebreich mentioned CERVELLO'S METHOD OF TREATMENT OF PHTHISIS.

He said the one great point was to raise the vital power of the cells and their power of resistance to the tubercle bacilli and other toxins. Commencing disease could be recovered from. One could not stand still at that, however, but had to go back to pharmacodynamics. Cervello had done this. He heated a formaline iodine preparation at a spirit lamp whereby formaline vapour was given off in the sick room, where the patient was made to breathe it for hours together. It caused no irritation of the air passages. Cervello, who had the finest sanatorium in the world at Palermo, had, according to his own statements, obtained very favourable results in his cases.

In the *Monatsch. Prak. Dermatol.* 99, Bd. 28 Unna warmly recommends the white indiarubber sticking plaster on spools of the Fabrik Becersdorf and Co., which has for him during the past few years become the means of fixature par excellence, wherever such is required whether on parts freely movable (knee and elbow) or elsewhere. It has not the energetic action of the zinc oxide, plastermull and zinc oxide parablaster in disease of the skin, but its absolute non-irritability and its cheapness, and its sticking properties render it superior in many ways. It is the ideal of a sticking plaster, and will certainly be the sticking plaster of the future. It can be procured not only in the ordinary breadth, but also in five different widths, 1.35 to 7.5 cm. and in lengths of 5 to 10 m.

ANTI-PNEUMOCOCCUS SERUM IN THE TREATMENT OF PNEUMONIA.

According to the *Deutsch. Med. Zeitung*, 98 99. Herren Banti and Pieraccini have made a prolonged and careful inquiry into the subject of the above-named treatment of pneumonia in the S. Maria Nuova Hospital in Florence, with the result of convincing both that the anti-pneumococcus serum has no influence whatever on the length of the disease, its symptoms or its complications. Neither was the mortality from the disease diminished in the slightest.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, February 24th, 1900.

GANGLIA.

At the last meeting of the Gesellschaft der Aerzte Budinger showed a male patient who had suffered from a ganglion on the dorsum of the left foot some years. A few months ago he slipped and fell, hurting the ganglion which suddenly enlarged from the third toe to the fifth, which Budinger diagnosed as a hæmatoma. He operated under this impression, but found the tendon as well as the binding sheath, but no pathological change could be observed in the tendon this was fastened with a suture, and the wound closed without any bad effect. He attempted to demonstrate the mechanism of this accident by another in the terminal phalanx.

SYRINGOMYELIA.

Schlesinger next exhibited two cases of syringomyelia

with unusually complex symptoms. The first had the right arm constantly turning which caused the patient considerable pain. Along the entire right side from foot, hip, thorax, neck, face to head the tactile sensation was exalted to a degree of pain to the patient, as well as the temperature sensation. The right shoulder was dislocated, and the scapula could be carried far away from its natural position. The morbid process he concluded had penetrated to the upper part of the cord, as well as the medulla oblongata.

The second case commenced after an accident to the left hand which gradually became emaciated, this emaciation extending up the entire limb, although the muscles were atrophied fibrillary contractions were present. The muscular power of the arm was diminished but the tendon reflex was increased. The sensation was partially gone in both arms from the hands to the elbows. During the last two years fluid food was occasionally regurgitated through the nose; this temporary bulbar paralysis is not a common attendant in the disease, although prominent in this case. There was, however, an absence of atrophy of both temporal muscles and Dupuytren's tendon contractions which are usually associated with the symptoms of springomyelia.

SCLERODERMA.

Spiegler brought forward a young woman with scleroderma having a reddish-brown colour, on the right mamma, about the size of a child's hand. When it first appeared it had a bright red appearance with well defined margin which led to the erroneous diagnosis of erysipelas.

The aetiology in this case was very obscure as there was no disturbance of nerve system, or pressure of corsets to account for the morbid changes; yet the latter must be accepted as suspicious, although subjectively no direct testimony can be vouchsafed on its behalf. In very sensitive skins very slight causes occasion œdema, which afterwards become sclerotic. There is one case on record where the wearing of a vest produced a similar change.

ENTEROPTOSIS.

Herzfeld finally read an exhaustive paper on enteroptosis (*εντερον*, intestine; *οπτος*, parched) which is seldom treated with the merit it deserves. It is more commonly associated with the female sex although it is not unknown in the male sex also. It is especially peculiar to a disturbed state of the digestive organs, and may be located to the stomach by the symptom of loss of appetite, a constant hungry feeling, or pain after taking food as if pressed or struck; or it may be located to the bowel by the presence of constipation, sudden diarrhoea, flatus, increase of abdomen with a swollen feeling, &c. These conditions often lead to severe discomfort, inability to move or work, even impeding the respiration, producing alarming palpitation, which may end in a disturbance of the circulation, vertigo, cephalalgia, nervous troubles, and rapid emaciation.

Glénard first attempted to demonstrate to the profession that this state was due to a lax condition of the ligaments in the flexura coli hepatica, thus permitting of a sinking of the colon ascendens and transversum, which subsequently produced a dragging on the other surrounding organs.

This theory is now almost exploded, as the causes may be so numerous and the symptoms so varied that no single fact can be charged with the offence. It is often met with from thoracic pressure, enlargement of the

liver, distension of the bowel, tight lacing, pregnancy, &c., &c.; indeed, anything that will reduce the tonus of the abdominal coverings may produce it. Hence it may be due to external causes as well as internal, being due to anything that disturbs the normal resistance. Herzfeld believes that the real cause is due to a dilated form of the blood vessels remaining after any of these causes that subsequently produce a chronic hyperæmia with general disturbance of the circulatory system evinced by the later stages of anæmia, excessive menstrual hæmorrhage, &c., &c.

The therapy most successful is nutrient dietetics, baths, massage, proper body supports, both external and internal, electricity, gymnastics, &c., &c., combined with constant regulation of all the internal organs.

Special Article.

THE ENGLISH MEDICAL MAN IN THE TRANSVAAL.

THE medical man who wishes to succeed in the Transvaal must be prepared to forego most of the ordinary comforts of life, and to rough it in the most literal sense of the word. Ninety per cent. of the population of the Transvaal lives away from the towns and villages, and it is a common occurrence for a doctor to be called on to start away for a sixty or seventy miles ride at any hour of the night or day. The Boers, to a great extent, depend on their own homely remedies in any slight illness. Should these not prove efficacious the trading store will be ransacked for some patent remedy, and in the event of this also failing to have the desired effect a messenger will be despatched post-haste for the doctor. Every medical man who goes to the Transvaal is not an expert horseman, but as many of the people live in inaccessible parts of country, which can only be reached by an ordinary conveyance by making a long détour, and as time is, of course, of the first importance that doctor will, as a rule, sacrifice his personal feelings, and start away on horseback. During the time he will be away from home he will have to trust to "pot luck." He will have to sleep in beds of every degree of hardness, and sometimes in no bed at all, he will have to live on boiled mutton and coarse brown bread, washed down with muddy coffee. He may be away three days, he may be away a week, probably to find on his return another call awaiting him from some other direction. It may be also that the doctor has gone to all this trouble for nothing. On one occasion a doctor was summoned to attend a sick Boer. On his arrival at the farm the "patient" met him at the door, and said that "he was alright again now, and so he (the doctor) had better have a cup of coffee and rest his horse before he started off back again." In this case the doctor had ridden forty-seven miles at this man's summons. The patient had been prostrated with a severe attack of cramp in the stomach, but repeated applications of hot water externally, and Dop brandy internally, had relieved him, and he was, as he said, "alright" when the doctor arrived. Not a word was mentioned about payment and when the doctor sent in his account the Boer seemed quite annoyed. "Why," he said, "I was alright when he arrived, he did not do anything for me," and it was only after the Landdrost had been called in to intervene

that the doctor received a portion of his account. The English doctor in the Transvaal has a powerful rival in the Hollanders. The latter can of course speak the language sufficiently to make himself understood and can understand the Boer himself (for the Hollander speaks a different language to the Boer), but once the Englishman picks up the "Taal" he generally forges ahead, for whatever his feelings towards us may be the Boer believes the Englishman is the most "slim" person in the world, and would always rather consult an Englishman than anyone else, provided that he can explain matters to him. There will be a great opening for young medical men in the Transvaal once the present "difficulty" is over.

The Operating Theatres.

ST. THOMAS'S HOSPITAL.

PAROVARIAN TUMOUR WITH ROTATION OF PEDICLE AND ADHERENT INTESTINES.—MR. W. ANDERSON operated on a woman, æt. 43, who was admitted with a tumour in the lower part of the abdomen, associated with symptoms of localised peritonitis. She said that she had noticed the tumour twelve months before, but during the past three weeks it had been apparently increasing in size, and was associated with a good deal of local tenderness. On examination a rounded tumour was found extending across the middle line into the right iliac fossa, and probably from the left side, where the growth appeared to have commenced. The intestines were displaced upwards and to the left side, and a certain degree of tenderness was noticeable in the latter situation. An incision was made a little to the left of the median line below the umbilicus; on introducing the hand, the tumour could be felt tense and oval; the exposed surface was somewhat dull and dark, and showed one or two flakes of lymph; on tapping with a small trocar a quantity of reddish brown fluid escaped, and after complete emptying the cyst was partially withdrawn from the abdomen. Several coils of small intestine and sigmoid flexure were then found adherent to the left side of the tumour near its pedicle, and the growth in this neighbourhood showed signs of extensive inflammation. The adhesions, which were apparently of some week or ten days duration, were broken down and cut through, and the pedicle when freed was found to have undergone rotation through about two-thirds of a circle. This was then ligatured strongly, and the tumour removed. The opposite ovary and broad ligament were found to be normal. The abdomen was then closed, separate stitches being used for the peritoneum, muscular walls, and skin. Mr. Anderson remarked that this was a case of parovarian cyst, which had undergone a partial rotation and consequent inflammation, the adjacent intestines had become glued to the growth in the neighbourhood of the pedicle, the point of maximum inflammation, but fortunately the adhesions were neither dense nor vascular. The danger caused by this condition was not likely to be an immediate one, and the patient would probably recover within the usual period after a successful operation but it would be necessary to watch for a long period for the possible supervention of intestinal obstruction secondary to the somewhat extensive peritoneal adhesions between so many coils of gut.

OPERATION FOR VENTRAL HERNIA.—MR. BATTLE operated on a woman, æt. about 40, who was the subject of ventral hernia. Ten years ago ovariectomy was performed, and the scar remained well for some months, but gradually, in consequence of increasing corpulence and two or three confinements it had yielded irregularly and permitted of escape of omentum. For some days the lower part of the swelling had been painful and she had suffered much discomfort; she had also suffered from troublesome cough. On admission she was a big, stout, plethoric woman weighing 14 to 15 stone, who presented an irregular swelling in the middle line under the lower part of an old scar. The lower part of the swelling was obscured by redness and œdema of the skin, whilst the skin over the upper part was thickened from the œdema. It was of irregular shape, lobulated, and whilst some of the lobules could be partly reduced the majority could not be pushed back, and this was more especially the case with the inflamed part. There was a slight rise of temperature, but otherwise, beyond the pain caused in the tumour by her coughing, she had no symptoms. She was kept in bed for some days, and hot fomentations applied to the abdomen, whilst the cough was treated with appropriate medicines. When inflammation had subsided and her cough improved a radical cure of the hernia was undertaken. An incision was made on the right side of the swelling, and the adherent omentum separated from numerous irregular loculi, and returned into the abdominal cavity. There was more than one opening leading through the middle line, so that the hernia might be called a compound one; the lowermost of these openings was occupied by adherent omentum, which had been recently inflamed, and the interior of the loculus, to which this was attached contained a rounded body about the size of a walnut, which was attached to the peritoneum lining the sac by recent adhesions; there seemed no other source of vascular supply. It appeared probable that this unusual body was separated from the omentum and changed by inflammation. There had probably been some hæmorrhage into it. The whole of the sac was now dissected away from the edge of the opening to which it was adherent, and the abdominal wall defined in three layers, peritoneum and subperitoneal tissue, united by a row of interrupted sutures, the fibrous tissue and muscular coat, where exposed, were sutured first of all in a single layer, and then a reinforcing layer was inserted from side to side like Lembert's sutures, and the parts laced together. The skin was then closed over it. A drainage tube was put in to be retained 24 hours. Mr. Battle said that it was a case in which radical cure should be attempted, for the condition was getting worse from month to month, and the patient suffered much pain. If nothing were done, it was very probable that strangulation would ensue at some time when she was suffering from bronchitis, and was unable to bear the necessary anæsthetic. He considered the reinforcing stitching he had put in effected a considerable strengthening of the wall and the union at that point would be very strong. He had used this method in similar cases before, and it had given him satisfaction. The finding of the rounded body referred to above was interesting, he thought, but it was difficult to say the exact manner in which it had been formed.

It looked fatty; there had been hæmorrhage into it, and recent inflammation around it.

It is satisfactory to say that a fortnight after operation the patient was going on well, although the anæsthetic had caused a temporary return of the bronchial cough.

“SALUS POPULI SUPREMA LEX.”

WEDNESDAY, FEBRUARY 28, 1900.

THE MORTALITY FROM DISEASE AT THE WAR.

In every campaign conducted upon a large scale the mortality from disease among the troops is expected to reach a high ratio, for despite the care that may be taken to attend to sanitary and hygienic details, the conditions which conduce to disease are everywhere present. A few of these may be mentioned. In the first place the food and water supplies are necessarily for the most part defective in armies on active service. The exigencies of the operations in progress make it impossible for the troops to receive proper nourishment; the food may be poor in quality, or lacking in quantity, while the water supply has to be drawn from the district in which the army is operating. Thus, while for a time the health of the troops may remain fairly good, before long the unavoidable privations and demands upon their strength begin to be felt, and disease in some form or another acquires a prevalence which tends generally to increase with the progress of the campaign. So far as our forces in South Africa are concerned, no excessive death-rate from disease has up to the present been recorded. This is not surprising in view of the natural healthiness of the climate. But the signs are not wanting that the trials of the campaign are beginning to tell upon the troops. Of course, in the beleaguered towns such as Ladysmith, and, until lately, Kimberley, a high and increasing mortality has obtained; this, however,

has been only the natural sequence of the special and more or less desperate conditions to which the inhabitants and troops were exposed. In Kimberley, for example, some weeks before its relief was accomplished by General French, the community were reduced to eating horseflesh, and we learn that this proved so distasteful to the women and children that they refused to partake of it, and preferred to go without solid food of this description. There is nothing, then, surprising in the statement that the mortality among the children was exceeding high during the siege owing to lack of insufficient nourishment. Then with regard to Ladysmith the reports show that many cases of enteric and dysentery have occurred therein since its investment. In accounting for this, no doubt, it is needful to recollect the recklessness of the average soldier who, while suffering from severe thirst, is apt to be very careless as to the water that he drinks. In proof thereof, it has been stated that at the fight on the Modder River the troops passed a pond, and, utterly regardless of the apparently foetid condition of the water, were about to quench their thirst by drinking from it. The common sense, however, of the officers prevented them from carrying their purpose into effect. Stringent orders were issued forbidding the men to drink the water, and by this timely exercise of authority in all probability many a man was saved from an attack either of dysentery or typhoid fever. The real point, however, upon which reflection cannot fail to be concentrated in this connection is that the lessons afforded by the deaths from disease are capable of teaching very little. So far as the prevalence of typhoid is concerned at Ladysmith, the strong probability is that most of it has been due to the neglect of ordinary precautions. At all events, this conclusion is only a reasonable one, for it is natural to assume that persons residing in a town which is being daily bombarded would not be much disposed to trouble about the boiling of their drinking water when most of their time was taken up in avoiding bursting shells from the enemy. Thus the prevalence of dysentery—no doubt largely a water-borne disease—and typhoid is capable of being mainly accounted for. It is also of interest here to recall that after the battle of Omdurman many deaths from enteric subsequently took place and the source of the disease was traced to the foul water which the men drank from a ditch alongside the town, while oppressed with an overwhelming thirst. It seems indisputable, therefore, that nothing is to be learnt from the mortality rate from disease which attends warfare; most of the deaths, under ordinary circumstances, would presumably be prevented by attention to those measures of precaution such as prudence and knowledge would dictate. But the circumstances are always far removed from the ordinary, and matters of more urgent moment claim the almost sole attention of all engaged in the campaign; consequently it happens that matters of health, important though they be, are apt to be neglected, with the result that a heavy death toll is exacted, and many valuable

lives lost, which might have been saved had better care been taken.

THE HOUSING OF THE WORKING CLASSES.

THE social importance of the movement that has been reduced to practical legislation in an Act bearing the above title must be apparent to everyone who has pondered the problems of latter-day civilised life. The health of the community, a mainstay of the national edifice second only to its wealth, is closely involved in the wisdom or otherwise with which this question is handled. When, therefore, it was known definitely that the present Government, the "strongest of modern times," were about to consolidate and amend the Housing of the Working Classes Act, 1890, it was generally hoped that Parliament would be asked to approve a measure characterised by strength, breadth and soul-convincing thoroughness. Such anticipations, however, have been doomed to disappointment. The great occasion has come and gone, the mountains have laboured, and a *ridiculus mus* has been brought forth in place of the sturdy young giant whose advent was not unreasonably expected. Last Thursday Mr. Chaplin obtained leave to introduce a Bill to amend the third part of the Act of 1890 relating to the Housing of the Working Classes. He proposed to give power to the London County Council, and to other local councils throughout the country, to acquire land beyond their area for the purpose of providing suitable dwellings for the working classes. The concession therein involved is valuable, but it does not touch the vital defect of the 1890 Act, that is to say, its cumbrous and costly machinery. Under present conditions the Act is shelved by the majority of Medical Officers of Health, except so far as a limited use of Part II. is concerned. It has been made apparent to them by experience that it is easier to close under the Public Health Acts, and better where a house is not too bad to be put in tolerable sanitary order. For the benefit of readers who are not conversant with the Housing of the Working Classes Act it may be well to set forth briefly a few of the chief features of that well-intentioned but disappointing effort of legislation. The Act is divided into three main parts. Part I. deals with unhealthy areas, both as to clearance and re-housing schemes. Part II. deals chiefly with dwelling-houses unfit for human habitation, secondly with their demolition, and thirdly with the removal of obstructive buildings. Part III. gives power to local authorities to buy land within their districts and to erect lodging-houses for the working classes, or to acquire suitable houses for the same purpose. In London the administration of Part III. is vested in the London County Council and in the country powers are obtainable with sanction of the Local Government Board. A curious anomaly arises from this arrangement, inasmuch as a small rural district can thus obtain facilities that are denied to rich and powerful Metropolitan Vestries and Boards of Works. It is impos-

sible to enter at length into the details of the present Act, but the broad statement may be made that for confusion, complication, and inadequacy it stands well-nigh unrivalled. Mr. Chaplin has done little in the direction of remedying those deficiencies. Dealing with Part III., he proposes to grant local authorities power, as already stated, to acquire land for purposes of housing outside the limits of their own jurisdiction. His only other proposal is to simplify procedure in rural districts by dispensing with the necessity of approval of the Local Government Board, and substituting that of County Councils. Mr. Chaplin's amendments, to say the least, do not bear the stamp of great statesmanship. So far as London is concerned, from November next, under the recent London Government Act, the new local authorities thereby created will have power to buy land outside their own district for the housing of the working classes. This meagre instalment of legislation cannot be regarded with any degree of enthusiasm. The President of the Local Government Board has neglected the opportunity of erecting for himself a monument more enduring than brass in the shape of a great Act. As Sir Walter Foster remarked in the Commons, the question was one of tremendous importance affecting tens of thousands of people in London and hundreds of thousands elsewhere, who were living under conditions where decency was impossible and morality a miracle. That proposition certainly presents the pith of the matter with a direction of statement that is always most desirable in relation to public health matters. The Bill has been read a first time, but it is to be hoped that it will not be allowed to become law except in a considerably amplified and amended form. As it stands, the Bill is a feeble, inadequate, and unsatisfying compromise, embodying the worst defects of patchwork legislation. Instead of the bread craved for by ardent sanitarians, Mr. Chaplin has incontinently thrown them a stone. This question serves to demonstrate once again the absolute need of a strong body of medical men in the House of Commons. The Government that pottered the principle of compulsory vaccination is hardly likely to show greater breadth and intelligence in dealing with other matters of prime importance to the community in the practical administration of preventive medicine.

IS SUICIDE ON THE INCREASE?

SIR JOHN SIBBALD has for some years been known as a special authority on the statistics of suicide, a subject to which he has given very careful attention, from which he has drawn very cautious and, which will be admitted by those best qualified to judge, very sound deductions. A few days ago he delivered before the Royal Society of Edinburgh, an address on "The Statistics of Suicide in Scotland," and his conclusions will be read with interest on this side of the border, as well as on the north, because he has dealt with a subject regarding which

there have been too many pessimistic views, and moreover, he has dealt with it in a manner which leaves little doubt as to the result. He pointed out that the numbers given in the Registrar-General's reports showed a steady increase in Scotland just as shown by the official numbers for almost every other country. The Scotch figures showed an increase from an average rate of forty per million in the five years 1865-1869 to fifty-four in the years 1890-1894, an increase of 35 per cent in thirty years. The English rates had been persistently higher than the Scotch, but their proportional increase was somewhat less. The figures had been generally accepted as showing that suicide had increased to a great and perhaps alarming extent in recent years. Sir John is quite satisfied that it is wrong to accept that view as well founded. In his words, the time has now come for subjecting such figures to careful criticism before accepting them as correct representations of the facts. We agree with him that in these, as in other similar sets of statistics, there is too great a tendency to accept official figures without carefully weighing their value, and without noting the fact that their value at one period may be different to their value at a subsequent period. In regard to suicide, Sir John observes, the state of public feeling and the degree of efficiency of the registering machinery must be kept in view. It is well known that in recent times great changes have taken place in public feeling in regard to this matter. The belief that an act of suicide necessarily involved disgrace has greatly diminished, since suicide has been recognised to be, in at least a large proportion of cases, the result of mental disease, and in consequence of this change of opinion efforts to conceal its occurrence have correspondingly decreased. The administrative machinery for ascertaining the occurrence of suicide has also, during recent years, been developed and made more efficient. How far we should accept this statement of Sir John Sibbald's may be a matter of opinion. There is certainly a considerable element of truth in it, particularly as regards the last clause of the statement, but there is just a chance that we may make too much of the argument that suicide is less regarded as a disgrace and more regarded as a result of disease than formerly. We may, however, pass on to some points of practical interest affecting the subject, points which Sir John clearly drew out in bold relief. In subjecting the official figures to critical examination he drew attention to the fact that all suicides in Scotland—and the same is true of England—were due to wounding, poisoning, drowning, and hanging, with the exception of eight per cent. due to other methods. He very pertinently observed that this fact is of great assistance in examining the value of the figures, and in determining whether certain deaths were due to suicide or not. Thus, for example, a death from hanging could hardly be concealed, and when known, could hardly be regarded otherwise than as suicidal. He, therefore considers it an important fact that during the thirty years already mentioned the rate of hanging in Scotland has remained

unchanged, being sixteen for the first fifteen years, and sixteen for the last fifteen years. It is instructive to find that in England the rate of hanging is also practically unchanged, being twenty-six for the first fifteen years, and twenty-five during the last fifteen years. Into further details space forbids our entering, but we may say this with convictions optimistic, and we may almost say, justifiably optimistic, that certainly it would be foolhardy for any one to step forward now and attempt to demonstrate that suicide is on the increase. It is said that the percentage of suicides is greater on the east coast than on the west, and what the real explanation of this may be is likely to be matter of dispute for the present, for it can scarcely be a mere question of east wind *versus* west wind, though it is possible there may be something in the exposure, but we cannot exactly say why. Dr. Clouston, in discussing the paper, trots out his old theory that excess of alcohol induces to a condition of brain which frequently leads to suicide. This, however, is probably being made too much of. We, however, join with Dr. Clouston in saying that "up to the reading of Sir John Sibbald's paper, all recent authors on the subject had put down suicide as being an increasing quantity in modern times; but his statistics and his mode of looking at things would cause all to put a point of interrogation at what perhaps would have otherwise been an universal conclusion."

Notes on Current Topics.

Quack Medicines and their Increasing Sale.

If a quack may be defined "as a boastful pretender to knowledge which he does not possess," we presume that a quack medicine may be described as "a secret concoction for which virtues are claimed in a pretentious and ignorant manner." In connection with this subject the Folkestone Medical Society recently passed a resolution to the effect that "this society is of opinion that the use of patent and proprietary medicines is largely on the increase, and is a public danger." This was a very sound and practical conclusion to have arrived at, but it will not be of much avail unless something more is done to bring it under notice. The Folkestone Medical Society would be inaugurating a good work if they became the pioneers in a campaign against the sale of quack medicines. They might issue copies of their resolution to other medical societies, and, if possible, obtain the concurrence of the latter. Moreover, they might attempt to gain an authoritative reply to the question regarding the necessity of bringing forward legislative measures bearing upon the subject. No doubt a law should be in force compelling the proprietor of every quack medicine to publish the formula of the latter with every package that he sells of his stuff. This, as is well known, is the rule which obtains in Germany, and there is no possible reason for not adopting it in this country. For the sum, however, of £230,000, which represents the annual amount of

duty paid on patent medicines, the Government have always refused to favour any proposal of the kind. They prefer to encourage the trade in quack concoctions on account of the revenue which they derive from the duty on the sale thereof, thus quite ignoring the harm which possibly results from the indiscriminate and wholesale dosing of the public with unnecessary and often undesirable drugs. Of course, the argument may be advanced that the public are under no compulsion to dose themselves with the quacks' alluring concoctions, but the answer is that the stamp which the Government issue as proof of payment of duty is regarded most generally by the public in the light of a guarantee that the concoctions are trustworthy and authorised. Even if some steps were taken by the Government to indicate that this was not the case, a great point, no doubt, would be gained, but experience in the past has shown that no legislative interference with the sale of quack commodities is ever likely to be undertaken by the Government of the day.

The Health of Mr. Treves and his Nurses.

The Central News Agency has reported that Mr. Treves has been ill from a bad attack of dysentery, and has had to leave the front, and go down to the coast in order to recuperate. If his health permits of it, however, he will return to the Tugela for a time, but his intention is to leave for England in the course of next month, some pressing engagements requiring him to do so. With respect to the health of his nurses, it was reported a short time ago that one of them had died from typhoid fever, but the mystery surrounding this rumour has been disposed of by Mr. Treves in a communication addressed to a contemporary. In a letter to our contemporary he states that the nurse in question, Miss Tarr, was attacked with dysentery, and the disease was of so severe a type that her life at one time was despaired of. She was removed to the hospital at Maritzburg, and here, it is satisfactory to note, she is now doing well. The other nurse appears to be in good health.

Chemists' Adulteration.

SANITARY authorities throughout the kingdom are beginning to show signs of an awakening interest in the Adulteration Acts. In one important direction there has hitherto been practically no control, namely, that of the purity of drug and druggists' wares. Last week a Camberwell chemist was prosecuted for selling camphorated oil which was not of the nature, substance, and quality of the article demanded by the purchaser. An analysis of the stuff showed that it contained 80 per cent. of mineral oil. According to the directions of the British Pharmacopœia one part of camphor should be dissolved in four parts of olive oil, so that the substitution was of a serious nature. The magistrate imposed a fine of £20 and costs. It is to be hoped that this exemplary decision will stimulate sanitary authorities in general to a more stringent administration of the Sale of Food

and Drugs Act. Chemists often try and justify themselves for giving unqualified medical advice to the public on the ground that medical men trespass on their preserves by dispensing physic. As we have often pointed out, however, medical men are legally entitled to make up medicines, whereas chemists are not legally qualified to give medical advice. The chemists, however, will now have an opportunity afforded them, so we may hope, of setting their own house in order. Fortunately we have a good standard for the purity of drugs in the shape of the British Pharmacopœia. The abolition of plurality among the public analysts will be a necessary step towards a sound supervision of the drugs and food-stuffs of the community.

A New Sanitary Board at St. Olave's.

SOUTH London is at times curiously unequal in its sanitary administration, and one of its latest feats has been the construction of what amounts to a new sanitary administration by superseding the Medical Officer of Health. Recently Dr. Bond, who acts in the capacity mentioned at St. Olave's, condemned certain premises. The Works and Finance Committee thereupon made an inspection, and reported that although certain ground-floor rooms were "undoubtedly dirty," some were already closed, and others would be much improved by whitewashing and cleansing. The committee did not consider there was any legal evidence that the premises were unfit for human habitation. Their report then went on to contravene Dr. Bond's statement that the deaths in those particular tenements were fifty per thousand living. In the absence of definite information as to how those figures were arrived at they refused to accept them, as they felt convinced there must have been some error in calculation. Dr. Bond was not allowed to offer any protest or explanation. This incident involves issues of wide importance to the future of preventive medicine, not only in St. Olave's but throughout the length and breadth of the United Kingdom. If such treatment of a Medical Officer of Health were tolerated, that official might be practically superseded by an irresponsible sub-committee in every sanitary authority in the kingdom. Fortunately, one or two small but weighty points appear to have been overlooked by the autocratic Works Committee of St. Olave's. First of all, Parliament vests full power in the Medical Officer of Health to condemn premises as unfit for human habitation upon his "opinion," which is therefore the one essential and indispensable precedent condition. St. Olave's has resolved to take no further action, but either the County Council or the Local Government Board will doubtless step in and do the work for this unruly Board of Works, which only a few months since was directly coerced by the Local Government Board.

THE Inebriates' Amendment (Scotland) Bill passed through Committee in the House of Lords early last week, and was then read a third time.

The Registrar-General for Ireland.

MR. ROBERT EDWIN MATHESON, Assistant Registrar-General, has been promoted by the Lord Lieutenant to the chief command of this very important department. We have, since the death of Dr. Grimshaw, urged the pre eminent claim of a member of our profession to occupy the position, and we adhere to the opinion that, neither in England nor in Ireland, should the Registrar-Generalship be held by anyone save a medical practitioner, and we maintain that for the duties of registering deaths, diseases, and births, no person can be competent without expert knowledge or expert assistance, which will, we trust, be provided for by the appointment of a capable medical statistician in association with Mr. Matheson. Nevertheless we recognise in Mr. Matheson the best man, outside our profession, who could have been selected. Mr. Matheson, who is a brother of Mr. C. L. Matheson, Q.C., has been connected with the department of which he now becomes chief since his eighteenth year, and has risen through all its sections, becoming, in the meantime, perfectly familiar with its work and routine. Since 1863, when he first became connected with the staff, many important changes have been made in the system of the great statistical office, and in the initiation of most of them Mr. Matheson has taken a prominent and useful part. Mr. Matheson studied law in the Middle Temple, London, and at the King's Inns, Dublin, and was called to the Irish Bar in 1875. In 1877 the position of secretary to the department was created, and Mr. Matheson, who by that time had passed through the leading sections of the department, was at once chosen as its first occupant,

Quack Disinfection.

THE weakness of medical legislation in protecting the public against the assaults of unqualified practice is every day abundantly illustrated in the annals of newspaper literature. An extraordinary case reported last week from the East-end of London shows that the province of the Medical Officer of Health is being invaded by the ubiquitous quack. From a report of the Medical Officer of Limehouse we learn that a herbalist informed him he had attended three diphtheria cases, and had subsequently disinfected the house. He went to the house, where he found three children affected, and three others also suffering from the disease were playing out in the street. He sent all six to the fever hospital, where five of them were promptly put on the dangerous list. The Vestry, on receiving this information, discussed at length the question as to whether the herbalist could be proceeded against. The opinion of the Medical Officer was that he might possibly be brought to book by the Pharmaceutical Society, but then only if he sold poison in his drugs. The Sanitary Committee was instructed to communicate with the Medical Council. As the subject thus opened up is one of first importance, both to the public and to the medical profession, it may be permissible to point out that the sale of medicines,

apart from poisons, is sufficient to bring an unqualified practitioner within the purview of the Society of Apothecaries. If the drugs were supplied for disinfecting purposes the offence would probably have been committed no less than if they were furnished in the form of Physic. This point we would suggest should be submitted to the Medical Defence Union, to which body all Medical Officers of Health should belong. The General Medical Council never undertakes the prosecution of unqualified quackery, but confines its attention to those who have passed the rubicon of medical qualification.

The Oral Instruction of the Deaf.

THE society for training teachers of the deaf, and for the diffusion of the so-called German, or pure oral system, held their festival dinner at the Hotel Cecil on Wednesday, the 21st inst., with Earl Egerton of Tatton in the chair, supported by a large number of distinguished members and guests. The existence and objects of this humane society are, perhaps, not as generally known and appreciated as they deserve to be. The aim of the society is to disseminate a knowledge of the oral system of instructing the congenitally deaf, which alone will enable these unfortunate children to speak like other people, and to follow the speech of others by watching their lips. In the realisation of this programme the first step was obviously to train a sufficient number of teachers, and the progress of the cause may be gauged by the fact that the society has trained and certificated 113 teachers of the deaf, who have been, or now are, engaged in teaching the deaf and dumb to speak and to understand others. Incidentally the society has been the means of inducing the Education Department to endorse the recommendation of the Royal Commission that all children thus afflicted should have the benefit of a course of training on these lines. The chairman, in proposing the toast of the evening, announced that large and immediate donations were required to put the finances of the society on a satisfactory footing, and enable it to proceed to the accomplishment of its programme, and in replying thereto, Dr. E. Symes Thompson, the chairman of committee, testified to the good work done and being done by the society, and endorsed the chairman's appeal for further support. We feel sure that the cause only has to be brought to the notice of the charitable public to secure the funds to carry on this beneficent work, though we are strongly of opinion that the duty of providing for the training of the poor "deaf and dumb" is one which should properly fall upon local educational authorities, the State intervening only to the extent of providing a supply of efficient teachers.

THE Midwives' Bill, as at present arranged, stands on second order for Ash Wednesday, but the chances of its coming up for discussion appear to be very remote. Even if it did the likelihood of its being "blocked" must be apparent.

Drunkenness and the Weather.

MR. E. G. DEXTER has taken the trouble to analyse the records of the New York City Police Force for three years in respect of arrests for drunkenness, and has considered their bearing as affected by the prevailing meteorological conditions. His results, published in a recent number of *Nature*, are singular enough to excite interest. He finds, for instance, that the prevalence of intoxication during the cold months was much in excess of that for the warm ones, December giving the police-court 47 per cent. more work than July. After discussing the bearing of certain possible factors, he points out that low temperatures made work for the police judge, while high ones lessened his labours. He suggests by way of explanation that the vitality of the body is lower in cold, than during moderately warm weather, and that this is the cause of the greater demand for stimulants, and on this hypothesis he urges that better heated tenements, warmer overcoats, and more nourishing food might do much to avert recourse to alcoholic stimulation during the cold season.

An Irregular Death Certificate.

At an inquest held in St. Giles' last week a curious irregularity in respect of the certification of the cause of death was brought to light. The child of a woman, who had been attended by a student of the British Lying-in-Hospital, Endell Street, died, and on information thereof being conveyed to Dr. G. H. D. Robinson, one of the visiting medical officers to the institution, this gentleman issued a certificate of the cause of death, leaving blank the name and address, and giving directions that it should be taken, with a letter he had written, to the coroner, in order that this official might decide whether or not the inquest was necessary. It transpired that the student had filled in the blanks, making it appear that Dr. Robinson had seen the child before death, which was not the case. The coroner pointed out the gross irregularity of such proceedings, and the jury expressed the opinion that the body of a deceased person should be viewed by the medical practitioner before signing the certificate, especially when he had not seen the deceased alive, or shortly before death, adding that as there was no residential medical officer at the British Lying-In Hospital the propriety of establishing telephonic communication between the institution and its medical officers might well be considered.

A Quasi-Live Burial.

A WELL-AUTHENTICATED case of what would shortly have been a case of live burial is reported from Southern Italy. A woman died, or was supposed to have died, as the result of a difficult labour, the foetus being left *in utero*. The body was placed in a coffin, and on the following day, before burial, when a photographer opened the coffin in accordance with the direction of the relatives, the woman was found to have turned over on her side, and close to her was the body of an infant, minus the arms which

had been removed during the obstetric operations. A judicial inquiry was set on foot, and the report concludes in favour of recovery from lethargy and death from suffocation. It is hardly necessary to point out that the change in position might conceivably have been caused by rough handling during removal to the mortuary, while the birth of the child is a phenomenon which has frequently been observed as the result of post mortem contraction associated with the onset of *rigor mortis*.

Medical Practice in Italy.

A CABINET Council has just been held in Italy for the purpose of considering the Bill shortly to be introduced into Parliament for regulating the practice of medicine by foreigners in that country. If the principle of reciprocity be not speedily recognised and adopted by the General Medical Council there appears to be every probability of restrictive measures being imposed. Now is the appointed time! There could not well be a more favourable moment for dealing with the subject, and it is to be hoped the members of council will give the matter their serious attention with this object in view.

The Physiological Effects of Boracic Acid.

MR. A. R. ANDERSON, F.R.C.S., of the Nottingham General Hospital, calls attention in a letter addressed to the *Lancet* to the physiological effect of boracic acid as observed by himself when giving the drug in ten to twenty grain doses in cases of bladder trouble. He has found that within a week or ten days symptoms of dyspepsia invariably developed, sufficiently acute to entail a tangible amount of discomfort; indeed so constant has this effect been that he is in the habit of warning patients to look out for it as an indication of the desirability of discontinuing its administration.

Immunity Against Scarlet Fever.

It is asserted that the Japanese enjoy a racial immunity against scarlet fever, and an American physician has even proposed to inoculate Anglo-Saxon children with the blood of Japanese infants as a means of securing protection against infection. This curious immunity, however, is not peculiar to the Japanese, for scarlet fever is reputed to be very rare in the western provinces of China, in Cochin China, Annam and Tonkin. It shows, moreover, little tendency to spread in South America, in Honduras, and in Jamaica. Whether this exemption is due to racial idiosyncrasy or to the climate being unfavourable to the specific organism is a moot question, but circumstances appear to point to race as the predominating influence. In India, where scarlet fever is also comparatively rare, the other exanthemata afflict the natives just as much as the white population. According to *La Médecine Moderne* there have only been twenty cases of the disease in twenty years among native troops numbering 235,000, while, during the same period, the European troops had sixty-two cases with two deaths. Even in France this disease is not as grave, nor does

it occur so frequently in epidemic form, as in Great Britain.

The Royal Army Medical Corps.

IN spite of recent reforms and ameliorations there is ample evidence that the medical service in the army is still far from being popular, a singular thing in view of the increasing difficulty experienced by young practitioners in finding suitable openings in civil practice. At the last competitive examination for the Army there were only seventeen candidates for forty vacancies, a discrepancy which is likely to be even more pronounced now that no less than a hundred commissions are to be offered. It is not merely a question of pay, for that factor does not seem to have operated in preventing candidates presenting themselves. It is rather the general, we might almost say the constitutional, want of consideration shown by military authorities for a very deserving, hard-working, and devoted class of officers. The government will now have to consider how best to create an effective medical organisation for the militia, yeomanry, and volunteers. One of the first points to consider will be the propriety of reducing the present ridiculous expenditure on uniform and equipment, which cannot but act as a deterrent to many practitioners who would otherwise be delighted to offer their services.

The Early Diagnosis of Impending Deafness.

ACCORDING to Dr. Bonnier, incipient deafness in persons who are predisposed thereto by reason of heredity, or as the result of chronic inflammatory affections of the nose or throat, may be diagnosed by the aid of a very simple test. The shaft of a large tuning fork in vibration is applied to any bony prominence, the knee, ankle, or elbow, or even on fleshy masses, such as the gluteal muscles, and the patient is asked whether, in addition to the vibration experienced at the site of contact, he also *hears* the tone. If really he perceives the transmitted sound, the ear being closed, there is evidence of paracusis, that is to say, a sign of impending deafness, for this form of paracusis, the author affirms, is peculiar to affections of the organ of hearing, and may precede all other manifestations of the infirmity.

Irish Local Government Amendment.

IT is some years since so impudent a Bill was offered to Parliament as the "Amendment" Bill presented by Mr. Tully, M.P., last week, which, to put it shortly, proposed that the central control of Guardians by the Government should be extinguished, and that the administration of the public business and the expenditure of the tax-payers money should be handed over to the village politicians in testimony to the admiration with which the nation regards their administrative capacity. The only thing which surprises us is that Mr. Tully, M.P., and his coadjutors can suppose that they gain anything by making themselves and their legislative proposals ridiculous

by such an enterprise as this. A nice place Ireland will be to live out of if ever the central control of these bucolic Solons is abandoned.

Dublin Hospitals.

THE election of surgeon to this hospital in place of Mr. Henry Moore, who has been elected to the surgeoncy of the City of Dublin Hospital, *vice* Mr. Wheeler, will take place on March 6th. In addition to Mr. Harry Croly, Mr. Burgess, and Mr. G. B. White, whom we have already named as candidates, we understand that Mr. Harvey, assistant surgeon to the Richmond Hospital, and Mr. Lane Joynt, of the Meath Hospital, and Mr. Albert Wynne are competitors. Dr. G. Jameson Johnston, Surgeon to the City of Dublin Hospital, has nearly recovered from the attack of diphtheria from which he has been suffering. Pending his resumption of the clinical work at that hospital, Mr. Harry Croly has been acting as his assistant surgeon in charge of his beds and of the class.

The Surgeoncy of the Queen's County Infirmary.

THE arguments in this case were heard by the Court of Queen's Bench in Dublin, on Tuesday, the 20th, and following days and yesterday. Tuesday was fixed for the delivery of the judgment of the court. The case seemed to depend a good deal upon the question whether, under the new law, the governors can dismiss an infirmary surgeon without satisfying the court that he was incapable or otherwise unfit for office, and whether, in this particular case, any such unfitness, on any ground, was capable of proof against the dismissed surgeon. We are debarred from expressing any opinion on these points as the court has not delivered its verdict at the time of writing. We can only say that, if the existing law is interpreted in the former sense, it will be a very serious matter for the Irish infirmary surgeons of the future who, in that case, would retain their positions only as long as they kept themselves strictly in line with the dominant politico-religious party.

The Proposed Midwives' Legislation.

THE editors of the *Lancet* recently sent post-cards to all registered English practitioners asking their opinion on the midwives' registration question. About a third of the number have so far replied, and of these 6,299, 1,817 consider that no legislation of the kind is called for, 1,530 of them adding that they are opposed to the Bill actually before Parliament. On the other hand, 1,323 are opposed to the Bill, but desire legislation for putting down unqualified practice. Further, 1,311 express themselves in favour of legislation on this subject as embodied in the present Bill. Lastly, 596 medical men declared their entire indifference on the subject. It follows that only 1,311 out of 6,299 are in favour of the Bill, a very significant result which cannot fail to carry weight with the Government in their attitude towards the proposed legislation.

THE Isolation Hospitals' Bill has been read a third time in the House of Lords without amendment, and has been sent to the Commons.

THE Dublin death-rate, which had fallen in three weeks from 37.0 per 1,000 of the population to 29.1, ran up again last week to 40.9. This has arisen, chiefly, from the prevalence of respiratory diseases and from influenza.

THE Society of Anaesthetists has enlarged its horizon in such wise that all duly-qualified practitioners who take an interest in the subject of anaesthesia and its production are eligible for membership.

THE Eighteenth Congress of Internal Medicine will be opened at Wiesbaden on April 18th, under the presidency of Prof. Von Jaksch, of Prague. The permanent secretary is Dr. Emil Pfeiffer, 13, Parkstrasse, Wiesbaden.

AT the next General Meeting of the British Laryngological, Rhinological, and Otological Association, which will take place on March 9th, at 4.30 p.m. at the Rooms of the Medical Society, 11, Chandos Street, W., a discussion will be held on "Conditions of the Throat and Larynx simulating and predisposing to Tuberculosis." It is to be opened by Mr. Lennox Browne.

IT is stated that Dr. Osler, the famous Professor of Medicine in John Hopkins University, Baltimore, is to be asked to allow himself to be nominated to the chair of the practice of physic in the University of Edinburgh. Though the Doctor is a Canadian by birth, he is a Fellow of the Royal Society and a Fellow of the Royal College of Physicians of London. His reputation is as great in the Old World as in he New.

THE Sanitary Institute Congress and Exhibition will not, as was arranged, take place this year at Nottingham. The large responsibilities which have been placed upon the county in connection with the war have made it difficult to assure the success of the meeting. With the approval of the Duke of Cambridge, president, it has therefore been decided to postpone the meeting.

THE application of a freshly-opened living pigeon to the head is still a popular remedy in France in cases of meningitis, and in the central market of Paris there is a poultry dealer whose speciality it is to provide pigeons for this purpose. She asserts that this branch of commerce is flourishing, and she has recently organised a farm in the environs for breeding therapeutical poultry.

THE latest suggestion for cutting the umbilical cord and keeping it aseptic is due to the ingenuity of Prof. Martin, of Griefswald, who advocates the use of curling tongs heated to a white heat. He first ligatures the cord close to its attachment, and then

burns it through, leaving a stump which is insusceptible of infection, and is safeguarded against accidental hæmorrhage.

PERSONAL.

MR. F. J. STEWARD has been appointed assistant surgeon to Guy's Hospital, and also assistant surgeon to the Great Ormond Street Hospital for Sick Children.

DR. DUDLEY BUXTON is to open a discussion on the "After-effects of Ether Inhalation, at the meeting of the Society of Anaesthetists on Friday next.

MR. W. A. SHEEN, son of Dr. Alfred Sheen, of Cardiff is about to proceed to the front as surgeon to the Imperial Yeomanry.

CAPTAIN J. E. CARTER and Lieutenant G. H. Goddard of the Royal Medical Service Corps, are among the wounded during Lord Roberts' recent operations.

SIR THOMAS SMITH, Bt., Surgeon Extraordinary to the Queen, has been appointed Honorary Consulting Surgeon to the Finsbury Dispensary, in succession to the late Sir James Paget.

THE marriage of Mr. Herbert Burrows Willett, eldest son of Mr. Alfred Willett, F.R.C.S., with Isobel, eldest daughter of the late James Matthews Duncan, M.D., F.R.S., will take place at Minstead, after Easter.

DR. F. W. PAVY, F.R.S., has been nominated by the Council for election to the office of President of the Royal Medical and Chirurgical Society at the Annual General Meeting on Thursday next (to-morrow).

MR. THOMAS MYLES, F.R.C.S., vice-president of the Royal College of Surgeons of Ireland and surgeon to Richmond Hospital, Dublin, has been appointed consulting surgeon to the Dublin Hospital for Diseases of the Skin.

SIR FRANCIS R. CRUISE, M.D., F.R.C.P.I., ex-president, Royal College Physicians, consulting physician to Mater Misericordiae Hospital, Dublin, and to the National Hospital for Consumption, has been appointed consulting physician to the Dublin Hospital for Diseases of the Skin.

MR. VICTOR HORSLEY is the recipient of formal congratulations proffered by the members of the Bradford and West Riding Medical Union "on the success with which he has struggled to defend the interests of medical practitioners against the continual neglect shown by the representatives of corporations on the General Medical Council."

WE regret to hear that Dr. Leith Napier, onetime of London, and recently of Adelaide, who has been acting as medical officer to the mounted contingent for South Africa, was thrown from his horse and sustained a fracture of the base of the skull. The latest bulletins testify to a slight improvement in the patient's condition.

THE war in South Africa has claimed another medical victim by the death from wounds of Captain Robt. H. Holt, of the Royal Army Medical Corps. He entered the Army Medical Service in 1892, and was gazetted a

captain in 1895. He was present during the fighting on the North-West India frontier in 1897-98, and received for his services the medal with clasps.

THE very valuable collection of literary and artistic treasures made by Dr. William Fraser, of Dublin, is to be sold early in March by Sotheby and Wilkinson. He was an enthusiastic collector of every good thing that was old. Etchings (including a unique selection of Albert Dürers), coins, medals, books, and old bindings, and, as he possessed rare powers of discrimination, and never bought faked-up antiquities, his collection has enormously increased in value. It has been sent to London for sale, chiefly because the purchasers of such treasures and the money to purchase with are scarce in Dr. Fraser's country.

MEDICAL SOCIETY OF LONDON.

At the meeting on Monday evening last (February 26th) Mr. MARMADUKE SHEILD reopened the adjourned discussion on "The Pathology and Treatment of Appendicitis," which occupied the entire evening. He was opposed to the administration of opium except in very moderate quantities, and he pointed out that the absence of induration over the cæcum was not in itself a reason for refusing operative treatment. He concurred in the view that rapidity of pulse was a very significant sign in these cases, and insisted on the importance of getting the bowels to act.

Dr. CAYLEY divided the cases into two great groups, those which might fairly be described as mild and those which were actually or potentially severe. The real difficulty arose in cases with severe initial symptoms in which, when seen early, it was virtually impossible to decide whether they would run a grave course or whether the symptoms would subside. Rapidity of pulse was significant, but they must take the collateral symptoms into consideration in deciding the question of operation. As to the administration of opium he thought it was of benefit provided it was not given until the question of operation or non-operation had been decided, and then only for the relief of pain and not continuously.

Mr. HARRISON CRIPPS thought that a mild first attack might be due to some accidental cause, and therefore did not necessarily require to be operated, but recurrence took the case out of that group, and indicated the lesion to be due to some abiding cause calling for surgical treatment. Operation during a quiescent period was practically devoid of risk, he himself had not had a fatal case, and Mr. Treves in his 150 cases had only two deaths. The presence or absence of swelling depended upon the position of the appendix and was not *per se* of any great significance. When there was very great induration it might be desirable to wait to see where the abscess would point. He objected to buried sutures, and said he had abandoned the use of any support to the abdomen after the operation.

Dr. HUNTER pointed out that appendicitis was always an infective lesion, so that the mild case of to-day might develop into the fulminating case of to-morrow. This fact should be borne in mind in deciding upon the treatment. He pointed out that suppuration often occurred after the disease had run a mild course of seven or eight days, and therefore whenever, after this lapse of time, there was even a slight rise of temperature he advised operation.

After some remarks by Mr. McAdam Eccles, Mr. MANSSELL MOULLIN said that in many cases in which the symptoms subsided suddenly this was due to discharge of matter into the intestine. In view of the risks which the condition entailed, the impossibility of ascertaining the exact nature of the lesion, and their inability to control its course, he urged that an operation was advisable in the majority of cases even at the risk of performing the operation in many cases which might have recovered without operation. The risks were small, and the patient was thereby guaranteed against recurrence.

Dr. LYNNE THOMAS, of Cardiff, said he had operated 41 times with only three deaths, and mentioned cases in which appendicitis had been diagnosed; in one of them it turned out to be pyosalpingitis, and in another an abscess of the right ovary. In a third case, he operated on a young woman and removed a healthy appendix. There was a recurrence of the symptoms, which yielded to a course of Weir Mitchell treatment.

After some remarks by Mr. Berry and Dr. F. Roberts (President), Dr. Allchin and Mr. Lockwood replied.

Literature.

TENTH ANNUAL REPORT NEW YORK STATE COMMISSION IN LUNACY.

THIS (Vol. i.) is a most elaborate work, and has an appearance of thoroughness. It is essentially American in character, and we might be disposed to criticise a profuseness of style and a method of administration which are of this essential character; but *cui bono*? Much of the statistical matter is of little interest, and the reports of committees on dress materials, marking ink, crockery, &c., is even more parochial than some of the methods which are contemptuously regarded, though we confess, extensively practised, by parochial authorities in this country. Why the time of medical superintendents should be taken up in full dress debates with motions and amendments on crockery we fail to understand, and why printers and bookbinders should be called on to immortalise such menial duties we are puzzled to explain. Unless that red tape is more than usually pleasing to the eye of our American cousins. This system must be very expensive, and though it may be good for the rank and file of the American machine it cannot tend towards economy of management on the higher efficiency of real medical work. The best part of this report, and even it might with advantage be pruned, in the interest of the reader, is a Preliminary Report on Dietsaries for hospitals for the insane. A certain amount of physiological explanation of an elementary character might be dispensed with. For these, however, who take the trouble to work their way through the report, repayment will result; for the differentiation of foods, their grouping according to nutritive equivalents, and the various tables of the state hospitals with their catalogue of foods, their percentage composition, and weights used should enable anyone who cares to take the trouble to frame ideal dietsaries in their relative physiological quantities, and in endless variety. We trust, when a continued report on this subject appears it will deal with the practical suggestions arising out of the first report.

Laboratory Notes.

CADBURY'S COCOA.

THE purity of this well-known cocoa is so established that it has come to be used as the representative standard of pure cocoa by analysts throughout the world. The use of cocoa as an alternative to tea and coffee has been for years advocated by the medical profession, seeing that it is a true food (which tea and coffee are not), and that it contains restorative properties peculiar to itself. In the early days of the Food and Drugs Act, when we analysed all the cocoas of commerce, it was common to find so-called cocoa to consist largely of mixtures of sugar and starch, with a comparatively small quantity of real cocoa, in some cases not more than a third or a quarter of the whole. When such mixtures are sold nowadays the fact of the addition of other substances must be set forth on the label, though it may be doubted if many persons take the trouble to ascertain clearly what it is they are buying; but it cannot be too clearly urged that pure cocoa, without any admixture whatsoever, is the best article for the healthy or sick, and that all mixtures should be avoided. In our exhaustive analyses some twenty years ago, Cadbury's came out of the ordeal as one of the very few pure

cocoas. We have recently conducted some further laboratory experiments, and find that this same cocoa contains no less than one-fifth of its weight of nitrogenous or flesh-forming matter, and more than one-quarter of its weight of the fat natural to cocoa, which is valuable as a nourishing and force-producing constituent. The characteristic natural alkaloid, namely, theobromine, was present to the extent of .9 per cent. The ash or mineral matter was that natural to pure cocoa, and amounted to .49 per cent., and it showed no added alkali.

The moisture was less than 5 per cent., that is to say, that the whole weight of cocoa purchased is actual food, whereas many ordinary foods consist largely of water, as, for instance, bread which contains half its weight of water, or butcher's meat which is nearly three-fourths water.

Microscopic examination confirmed the chemical analysis by showing the absence of all matter not naturally present in pure cocoa.

ECTHOL.

ECTHOL is the name given to a preparation containing the active principles of Echinacea and Thuja. Of these the former was originally introduced into therapeutics by Dr. H. F. C. Meyer as "an antispasmodic and an antidote for blood poisoning." In virtue of this property it is recommended in the treatment of malarial fever, cholera, furunculosis, infective sore throat, eczema, rheumatism, and dyspepsia. Echinacea is employed both internally and as a topical application, and it is stated to give excellent results in the treatment of poisoned wounds, snake-bites, insect stings, &c. Thuja is reputed to allay the pain, and promote the healing, of wounds and ulcers, and these properties have been turned to good account in gonorrhoea by using it as an injection.

Ecthol is a clear, brown fluid with an odour recalling that of valerian, and unquestionably possesses valuable sedative and antiseptic properties, rendering it useful in irritative dyspepsia, and, when applied externally, in cases of gonorrhoea, vaginitis, and erysipelas.

Medical News.

The Registration of Midwives.

COPY of a memorial addressed to the General Medical Council in May, 1899, by the Council of the British Gynaecological Society.—

"The Council of the British Gynaecological Society approach the General Medical Council with the view of securing on its part the fullest consideration of any proposed Bill dealing with the licensing of midwives, so as to prevent any direct or indirect infraction of the Medical Act of 1886.

"The Council, while recognising the necessity for such legislation as shall prevent incompetent women from acting as midwives or midwifery nurses, trusts that the General Medical Council will not lend its support to any Bill which does not adequately provide for the public safety nor protect the interests of the medical profession.

"The Council of the British Gynaecological Society would ask the General Medical Council to consider the many inherent difficulties which are inseparable from the recognition by the State of a new order of midwives, entitled by a registerable license to practice for gain, without direct medical control, the art of obstetrics.

"As one proof of the necessity for such deliberation on the part of the General Medical Council, the Council of the British Gynaecological Society would point to the obviously vague use of the term 'natural labour,' on the application of which term the entire construction of the present Bill is based.

"The Council regard it to be a function of the General Medical Council to take such measures as it may consider right to restrict the independent action of such midwifery or monthly nurses, in the conduct of parturition, as will prevent the assumption by them of those duties which rightly fall to the medical man alone to dis-

charge. Towards this end, the report of a sub-committee, as has been suggested by the direct representatives of the profession on the Medical Council, would appear to be both valuable and desirable.

"Without such limitations being imposed on women who are ignorant of all the collateral branches of medical science, on which the first principles of the obstetric art depend, and without any guarantee to insure a prompt appeal for medical supervision in the conduct of parturition when such is required from any cause whatsoever, the Council of the British Gynaecological Society views with concern the creation of a new and inferior grade of licensed practitioners.

"The extreme gravity of the question, and the influence which any legislation with regard to it must exert on the practice of obstetrics in this country, has induced the Council of the British Gynaecological Society, in the cause of medical science generally, and in defence of the art of midwifery in particular, to address the General Medical Council on the matter, and to respectfully ask its consideration of this Memorial."

Copy of the resolution adopted by the General Medical Council, with regard to the memorial of the British Gynaecological Society:—"That the memorial be acknowledged with thanks, and that the British Gynaecological Society be informed that the successive reports of the Committee to the Council will show that the considerations set forth in the Memorial have continually been kept in view by the Committee."

Chelsea Hospital for Women.

WE are asked to announce that the Chelsea Hospital for Women offers special facilities for the gratuitous treatment of wives of reservists suffering from diseases which come within its province. The annual general meeting of Governors of this institution will be held on Tuesday next at 3.30 p.m.

PASS LISTS.

Royal College of Surgeons in Ireland. Fellowship Examination.

MR. D. A. FITZGERALD having passed the necessary examination, has been admitted a Fellow of the College.

The following gentlemen have passed the primary part of this examination:—Mr. F. H. McC. C. Crawley, Mr. K. L. G. Gunn, Mr. S. H. Law, Mr. A. Charles, Mr. T. A. Dillon, and Mr. A. H. B. Hartford.

Apothecaries' Hall, Ireland.

THE following candidates have passed the under-mentioned professional examinations:—

Second Professional.—Richard Tracy, physiology and anatomy, H. W. Mason, anatomy.

Third Professional.—L. J. Farrell, pathology and hygiene and forensic medicine: S. Adye Curran, pathology and materia medica; J. D'Arcy Hamilton, pathology and forensic medicine: W. P. Harding, medicine and surgery; F. A. Bass, medicine and midwifery; A. J. Barnes, medicine, midwifery, and ophthalmic surgery; G. M. Sharpe, medicine, surgery, midwifery, and ophthalmology.

The following gentlemen have completed the final examination, and have been admitted licentiates of the Apothecaries' Hall, and are now qualified to practice medicine, surgery, and midwifery:—Frederick Ellis Bass, William Patrick Harding, and George Metcalfe Sharpe.

Society of Apothecaries of London.

DURING February Examinations the following candidates passed in:—

Surgery.—C. B. S. Ames (Sections I. and II.), C. A. W. Egan, W. J. H. Wepworth, O. E. Lemin (Section I.), R. V. A. Mosley (Sections I. and II.), S. Page (Section I.), A. Y. St. Leger (Section I.), N. Walmisley, A. J. Watson (Section I.)

Medicine.—C. B. S. Ames (Section II.), J. F. Hodgson, J. W. H. Morrison (Sections I. and II.), R. V. A. Mosley (Sections I. and II.), A. C. Oliver (Section I.)

Forensic Medicine.—J. F. Hodgson, J. W. H. Morrison, R. V. A. Mosley, A. C. Oliver.

Midwifery.—W. Alcock, C. E. C. Child, J. I. Halstead, J. F. Hodgson, G. J. W. Keigwin, A. E. Malaher, R. V. A. Mosley, E. A. Quirke, J. C. S. Rashleigh, M. J. Ryan.

The diploma of the Society (L.S.A. Lond.) was granted to the following candidates, entitling them to practice medicine, surgery, and midwifery:—C. B. S. Ames, C. A. W. Egan, W. J. H. Wepworth, R. V. A. Mosley, and N. Walmisley.

Notices to Correspondents, Short Letters, &c.

✉ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

MR. H. J. BROWN.—It may be so, but still the fact remains that urticaria may sometimes assume the hæmorrhagic form, and be attended with profuse hæmorrhage from mucous membranes. Why not call in a specialist in skin diseases? He would probably throw some light on the matter.

ETONENSIS.—The case you describe is undoubtedly one of Raynaud's disease. The symmetrical vasomotor disturbances and the myelitis and "blistering" of the finger tips constitute a group of symptoms that is quite typical. Raynaud's first description of the condition that now bears his name was made in a *Thesis* published in 1862. You will find all information as to this most interesting malady in an admirable monograph recently published by Dr. T. K. Munro, of Glasgow. There are many moot points as to the pathological and etiological relations of this condition, which is, perhaps, less rare than commonly supposed.

CIVIS.—Make a formal complaint to the Medical Officer of Health of your district. Your landlord is bound to keep the house in good sanitary repair.

L.R.C.P., M.R.C.S.—Certainly, we should regard any medical man who professed to treat primary syphilis without the aid of mercury as a charlatan. To order iodide of potassium for primary chancre is to proclaim the foolishness of the prescriber.

Meetings of the Societies and Lectures.

WEDNESDAY, FEBRUARY 28TH.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—4 p.m. Prof. A. Keith: The Results of an Investigation of the Anatomy of Man and Higher Primates to determine more accurately the Relationship of Man to Living and Extinct Forms.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY (West London Hospital, Hammersmith, W.).—Clinical Evening. The following Cases will be shown:—Mr. C. B. Keetley: (1) Radical Cure of Hernia ten years after Operation; (2) Case of Excision of the Pylorus.—Dr. C. Pope: (1) Case of Bradycardia in a Child; (2) Case of Abscess of Spleen cured by Drainage. Dr. S. Taylor: Case of Palsy of the Sixth, Seventh, and Eighth Cranial Nerves.—Dr. Abraham: Two Cases of Disease of the Skin.—Mr. Bidwell: (1) A Case of Nephrolithotomy; (2) Two Cases of Pyloroplasty.

LARYNGOLOGICAL SOCIETY OF LONDON (20, Hanover Square, W.).—5 p.m. Cases and Specimens will be shown by the following: Sir Felix Semon, Dr. Horne, Dr. Potter, Dr. F. well, Dr. St. Clair Thomson, Mr. Heath, Mr. Lake, Mr. Robinson, and Mr. Waggett.

WEST KENT MEDICO-CHIRURGICAL SOCIETY (Royal Kent Dispensary, Greenwich Road, S.E.).—8.45 p.m. Exhibition of Clinical Cases, Specimens, &c. (Living Cases will be shown first):—Dr. McCann and Dr. Ezard: Case of Ruptured Ovarian Cyst.—Dr. Adkins: A Case of Enteric Fever in which the whole of the Ulcers were transversely placed and Peyer's Patches not much affected.—Dr. Tootood: Cases from Lewisham Infirmary.—Mr. C. Williams: (1) Case of Caries of the Spine; (2) Cast, Specimen, and Skiagraph of Case of Congenital Hypertrophy of Great and Second Toes. Council Meeting.

SOCIETY OF ANÆSTHETISTS (20, Hanover Square, W.).—8.30 p.m. Adjourned Discussion on the After-Effects of Ether Inhalation on the Respiratory System (re-opened by Dr. Dudley Buxton).

DERMATOLOGICAL SOCIETY OF GREAT BRITAIN AND IRELAND (20, Hanover Square, W.).—4.30 p.m. Informal Exhibition of Cases. 5 p.m., Ordinary Meeting.

THURSDAY, MARCH 1ST.

HOSPITAL FOR DISEASES OF THE NERVOUS SYSTEM (73, Welbeck Street).—At 5 p.m. Clinical Demonstration. Dr. Dundas Grant: Cases of Aural and other Forms of Vertigo.

THE RONTGEN SOCIETY (20, Hanover Square).—8 p.m. Paper by Mr. J. H. Gardiner, "Measurements of the Absorbability of Röntgen Rays." Dr. Hugh Walsham will show skiagrams of two Cases of Renal Calculus before and after removal.

FRIDAY, MARCH 2ND, 1900.

ROYAL ACADEMY OF MEDICINE OF IRELAND.—Section of Surgery. Business papers:—1. Mr. J. S. McArdle, on the Position of Murphy's Button in Modern Surgery; 2. Mr. J. F. Knott, on Dupuytren's Contraction of the Palmar Fascia; 3. Mr. E. H. Taylor on the Operative Treatment of Cleft Palate. Living Exhibits. Mr. John Lentaigne: Case of Double Perforation of Small Intestine in Sac of Femoral Hernia by Piece of Bacon Bone. Card Specimens: (a) Portion of Bacon Bone Producing Intestinal Perforation in Sac of Femoral Hernia. (b) Cancer of Penis with Lymphatic Glands.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—4 p.m. Prof. A. Keith: The Results of an Investigation of the Anatomy of Man and Higher Primates to determine more accurately the Relationship of Man to Living and Extinct Forms.

Appointments.

BATLISS, RICHARD ARTHUR, M.R.C.S., L.R.C.P.Lond., Honorary Medical Officer to the Eastern Dispensary, Bath.

BELL, H. J., L.R.C.P., L.R.C.S.Ed., Medical Officer for the Mortlake Sanitary District of the Richmond (Surrey) Union.

BROOKS, J. H., M.D.Aberd., Medical Superintendent of the Infirmary and Medical Officer of the Workhouse, Mile End, London.

GOFFE, E. G. L., M.B.Lond., L.R.C.P., M.R.C.S., Assistant Medical Superintendent to the Lewisham Infirmary.

OLIVER, A. R., M.B., C.M.Glasg., Surgeon to the Glasgow Central Dispensary.

ORR, VIVIAN B., M.B., B.S.Melb., L.R.C.P., M.R.C.S., Assistant House Surgeon to the Westminster Hospital.

RICHARDSON, W. G. M.B., B.S.Durh., F.R.C.S.Eng., Assistant Surgeon to the Royal Infirmary, Newcastle-on-Tyne.

SELBY, J. S. E., L.R.C.P.Lond., M.R.C.S., Medical Officer for the Seventh Sanitary District of the Aylesbury Union.

SMITH, Sir THOS., Bart., F.R.C.S.Eng., Honorary Consulting Surgeon to the Finsbury Dispensary, London, vice Sir James Paget, Bart., deceased.

Vacancies.

Abbeyleix Union.—Temporary Medical Officer. Salary £3 3s. per week. Immediate application to James Finnegan, Clerk of Union. (See Advt.)

Abbeyleix Union.—Permanent Medical Officer. Salary £100 per annum as Medical Officer, and £20 per annum as Sanitary Officer, with usual Vaccination Fees. Application to James Finnegan, Clerk of Union. (See Advt.)

Bradford Royal Infirmary.—House Surgeon, unmarried. Salary £110 per annum, with board and residence.

Carmarthen Infirmary.—Resident Medical Officer, unmarried, for twelve months. Salary £100 per annum, with furnished apartments, board attendance, fire, gas, and washing.

Castlereagh Union.—Trained Infirmary Nurse. Salary £50 per annum, with rations and apartments. Application to M. Flanagan, Clerk of the Union.

Consumption Hospital, Ventnor.—Assistant Resident Medical Officer to the Royal National Hospital for Consumption. Salary £100, with board and residence. Immediate application to Dr. Parry. (See Advt.)

County Borough of Southampton.—Assistant Medical Officer of Health, unmarried. Salary £150 per annum, with residence and board. Apply to the Town Clerk, Southampton.

County Borough of Stockport.—Medical Officer of Health for five years. Salary £400 per annum, increasing annually by £25 to £500. Apply to the Town Clerk, Town Clerk's Office, Stockport.

Cumberland and Westmorland Asylum, Garlands, Carlisle.—Junior Assistant Medical Officer, unmarried. Salary £100 a year, with board and residence.

Durham County Asylum.—Assistant Medical Officer. Salary, commencing at £141, with board, lodging, washing and attendance. Apply to Medical Superintendent, Winterton, Ferryhill.

General Hospital, Nottingham.—Assistant House Physician for twelve months. Salary £100, with board, lodging, and washing in the hospital.

Great Northern Central Hospital, Holloway, London.—Junior House Surgeon for six months. Salary at the rate of £8 per annum, with board, lodging, and washing in the hospital. (See Advt.)

KING'S College, London.—Senior Medical Registrar and Tutor and Senior Surgical Registrar and Tutor. Also Professorship of Materia Medica and Therapeutics.

Newport and Monmouthshire Hospital, Newport, Mon.—House Surgeon. Salary £100 per annum, with board and residence. No stimulants provided.

Queen's College, Cork.—Professorship of Materia Medica. Apply to the Under Secretary, Dublin Castle. (See Advt.)

St. Mary's Hospital School, Paddington, W.—Demonstrator of Physiology. Salary £100 to £150.

Workshop Dispensary Hospital.—Resident Surgeon. Salary £120 per annum. Rooms, coal, gas, furniture, and housekeeper provided. Apply to Mr. Charles A. Whall, Workshop.

Births.

DICKSON.—On Feb. 25th, at Seardsdale Villas, Kensington, the wife of T. Hugh Dickson, M.A., M.R., of a daughter.

FAGGE.—On Feb. 20th, at St. Thomas's Street, S.E., the wife of C. H. Fagge, M.S., F.R.C.S., of a daughter.

KEELE.—On Feb. 30th, at St. Paul's Road, Highbury, the wife of David Keele, M.R.C.S., L.R.C.P., of a son.

Marriages.

COBB—WALKER.—On Feb. 21st, at All Saints', Leamington, Ernest Herbert Cobb, M.R.C.S., L.R.C.P.Lond., elder son of James F. Cobb, Esq., of 5, Cornwall Terrace, London, to Eleanor, second daughter of the Rev. F. J. Walker, late Rector of Frodesley, Shropshire.

KEKWICK—PRAIN.—On Feb. 22nd, at Blackness House, Dundee, John Kekwick, M.R.C.S., L.R.C.P., L.D.S.Eng., to Catherine, eldest daughter of John Easton Prain, of Dundee.

ROWLAND PLUMER.—On Feb. 20th, at Shoreham, Walter John Rowland, B.A.Lond., M.B.Durh., M.R.C.S., L.R.C.P., son of John Rowland, of Gwydyr House, Bromley, Kent, to Jessie daughter of Alfred S. Plumer, of Springwells, Steyning, Sussex.

Deaths.

CARDOZO.—On Feb. 19th, 1900, in London, Samuel Cardozo, M.D., aged 77 years.

DAVIS.—On Feb. 18th, at his residence, Crawford Square, London-derry, Thomas Davis, M.D., J.F., aged 82 years.

HOLT.—On Feb. 21st, from wounds received in action with Sir Redvers Buller's force in Natal, E. H. E. G. Holt, Captain Royal Army Medical Corps, aged 33.

JONES.—On Feb. 20th, at Ladysmith, of enteric fever, G. W. G. Jones, Lieut., Royal Army Medical Corps, aged 25.

The Medical Press and Circular.

"SALUS POPULI SUPREMA LEX."

No. 10.

The Lettsomian Lectures.

PRACTICAL OBSERVATIONS

ON

CANCER OF THE BREAST. (a)

By SIR WILLIAM M. BANKS, LL.D., F.R.C.S.

Surgeon to the Liverpool Royal Infirmary; Emeritus Professor of Anatomy in University College, Liverpool.

LECTURE I.

MR. PRESIDENT AND GENTLEMEN.—Naturally my first duty is to thank you for the honour you have done me in asking me to give the Lettsomian Lectures in the first year of the twentieth century. Let us fervently hope that long ere it has come to an end a remedy will be found for the fell scourge of which I propose to treat. I have in my consulting room the well-known engraving of the founders of this Society. I shall never look on the stiff but commanding figure of Quaker Lettsom as he stands in their midst without a feeling of pride that I have been permitted to be one of those privileged to assist in celebrating his name and fame. The roll of those who have delivered these lectures contains so many distinguished names that I may well feel some diffidence in trying to follow in their footsteps; but I take courage from the recollection that this is not the first time that the Medical Society has deputed me to address them.

EXPERIENCE AND STATISTICS IN MEDICINE.

When a man has to prepare an address the choice of a subject is generally a most difficult matter. If he has nothing of a very distinctly novel character to offer his hearers it is probably best for him to give them his experiences on the subject with which he is best acquainted. If he has any judgment and discretion in him he may do something useful in this way, because in our profession advances are so rapid that they are apt to become bewildering. The record of a long personal experience under such circumstances may be of service as a kind of steady medium. Moreover, these lectures, although nominally delivered to you, do really reach the majority of the medical public, and one of their prime uses is to present to that public at given periods a synoptical view of all that is known of the subjects they embrace up to the moment. I will endeavour then to put into them my experiences of cancer of the breast during the past 33 years in which I have been engaged in surgical practice. It is true that, in the absence of statistics, experience can only produce "impressions and recollections," and the professional statistician holds all "impressions and recollections" in the greatest contempt. He holds that figures can never lie. On the other hand it has long been painfully manifest that

nothing can be more lying and delusive than statistics if not properly used. In the first place their collection must be made with the utmost accuracy and with perfect purity of heart and calmness of mind. With medical statistics the temptation to gloss over and soften down unfavourable figures is very great, and requires that a man shall summon to his aid all his integrity. Again, when a man presents to you a vast mass of statistics, compiled at the expense of much time and labour, it is practically impossible to go over them with him, and you have no choice but to accept them. As a result many errors have been long handed down from book to book, until some disagreeable doubter has arisen who has exposed them. Finally, even when the statistics are absolutely correct, the most erroneous deductions may be drawn from them, and from the same figures two men may extract the most opposite conclusions. If anybody wants to know how statistics may be manipulated and applied let him consult the literature of the Anti-Contagious Diseases, Anti-vivisectionist and Anti-vaccinationist propaganda; all prepared by persons of the most superior virtue. Nobody wishes to deny to statistics their great value and their proper place, but one must also stand up for the value of those views which many successes and many failures have ingrained on the mind of any man endowed with an average amount of good sense and judgment. If, then, a man be not a waverer blown every way by the wind of opinion he ought, at the end of an experience extending over the life of a generation, to have come to certain firm and definite conclusions about many things, and if he proposes making these views public, he must express them in a firm and definite fashion. This necessarily exposes him to the charge of egotism and dogmatism. The former I shall endeavour to avoid as far as in me lies, but, should I occasionally become dogmatic, I pray you put it down to the exigencies of the situation, compelling me as they do to give my own particular views about cancer of the breast, while freely according to every other surgeon the liberty to advocate his views and declare mine entirely wrong.

THE INCREASE OF CANCEROUS DISEASE AND ITS CAUSE.

Before coming to cancer as it specially manifests itself in the female breast, I should like to say something on certain points on the general question of malignant disease, which legitimately forms part of our present subject. Most medical men are of opinion that the number of persons who die from cancer in proportion to the number of the population has been steadily increasing. Very voluminous statistics from the Registrar-General's returns and from the returns of deaths in individual towns and counties seem to prove this very emphatically. My own "impression," apart from any knowledge gained from statistics, is strongly to the same effect. It is true that the "impression" of a surgeon who sees a great deal of cancer must be received with care, for it is doubtless the case that,

(a) Delivered before the Medical Society of London, Monday, March 5th, 1900.

as a man's practice increases, he may see more of certain cases than he used to do, because his friends, knowing that he is interested in them, send them to him. Thus he may come to think that the same thing is happening in the practice of everybody, and that there is a general increase in those diseases all round, whereas the increase is in reality only in his own sphere of observation. In order to protect myself from falling into this mistake I have summoned up my recollection of the year 1861-2, when I was a dresser in the wards of Mr. Syme in the Edinburgh Royal Infirmary. Mr. Syme had a reputation then as indisputably the first surgeon in Scotland. So that, I am sure my old fellow-students of the period I mention will bear me out in saying that the pick of the surgical cases in the south of Scotland were sent to him. I have a very vivid recollection of the run of cases I saw, and possess a note book to-day containing many of them. Now cases of cancer, although not uncommon, were rare compared with the numbers in the practice of my colleagues at the Liverpool Royal Infirmary and myself at this moment. They were objects of curiosity and interest to us students. I can only remember once seeing a case of cancer of the rectum. So that I am able quite clearly, after an interval of eight and thirty years, to assert that the number of cases in the wards of any one of the surgeons of the Liverpool Royal Infirmary at this day is much larger than I can remember in the wards of so distinguished a man as Mr. Syme, who drew his patients from a great area. This is more than a mere impression. This is a fact. The arguments used against the alleged increase of cancer are that it is more apparent than real on account of the improved diagnosis of modern days producing greater accuracy in death certificates, and on account of autopsies being formerly the exception in hospital whereas they are now the rule. In his very able article in the *Practitioner* for April, 1899, Dr. Arthur Newsholme advocates these views with much ability. On these points I will, with your permission, gentlemen, once more revert to my student experience. I think it may be fairly admitted that the character of the medical teaching at any given epoch is a barometer which gives the level of the knowledge of the mass of practitioners at that same period. In 1861 Miller, Syme, Spence, and Patrick Watson were the chief surgical teachers in Edinburgh. I assert that their knowledge of surgical cancer on the surface of the body, and in the ends of the intestinal tract, was as accurate as that of any surgeon of the present day. Bennett, Laycock, Begbie, Gairdner, and Sanders taught medicine, and I am unable to see any notable difference between their ideas of internal cancer and their methods of diagnosing it as compared with now. If mention be made of the brain, spinal cord and nervous system generally, then, at the time I speak of, absolutely nothing was known about them, and the improvements in the diagnosis of them can only be appreciated by one who has witnessed the change. But this is not the case with the diagnosis of cancer. I do not like to say much about the increase in the number of autopsies at hospitals, because I cannot make a positive statement on the question beyond this, that in my student days at Edinburgh, and I imagine the same holds good of all the great London hospitals, every effort was made to secure post-mortem examinations when possible. One would too gladly wish that Dr. Newsholme were right, but immediately following his paper is one by Professor Boswell Bark, of Buffalo, who states that in England and Wales the cancer death-rate has risen from 1 out of 5,646 of population in 1840 to 1 out of every 1,306 of population in 1890; that is to say, that in fifty years the death-rate has increased between four and five times, and he makes this astonishing

statement: "A careful study of all these tables permits one to make the following startling prophecy. If for the next ten years the relative death-rates are maintained, we shall find that ten years from now, namely in 1909, there will be more deaths in New York State from cancer than from consumption, small-pox, and typhoid fever combined." With every wish, then, to give a good deal to the theory of better diagnosis and more numerous autopsies, I cannot bring myself to believe that they account for more than a moderate amount in the increase of cancer mortality.

LOCAL DISTRIBUTION.

Has locality anything to do with cancer? This is a matter upon which a great deal hinges, but from personal experience I cannot give any information. It is unlikely that any hospital surgeon will be able to do so, for he who has obtained any reputation for the operative treatment of cancer draws his patients from such varied sources that the question of locality as affecting them is void. On this subject information of any moment can only be obtained by collecting great masses of statistics, and even then the deductions therefrom will have to be made very cautiously and judiciously. The first attempt in this direction was made by Mr. Moore of the Middlesex Hospital, in 1865, and to him is also due the merit of being the first who boldly drew the attention of the profession to the inefficient operations for cancer which were performed in his day. To his courageous protest is due the modern principle of free removal. But, as we all know, Mr. Haviland's labours have been those of a lifetime, and his tables of statistics are a marvel. In 1868 to the Medical Society in this very room he read his first paper "On the Geographical Distribution of Cancer among Females throughout England and Wales the Decennial Period 1851-60." He found that 4.33 cases of cancer occurred in every 10,000 females, and 1.94 in every 10,000 males. Leaving untouched the decennial periods 1861-70 and 1871-80, he investigated 1881-90. He then found 7.30 cases in 10,000 females and 4.30 in 10,000 males; i.e., 0.42 more than double among males and 1.28 less than double among females. Admitting these statistics as true, two things are clear. 1. That there has been a great general increase of cancer all round. 2. That this increase is much more marked in males than in females.

The following are Mr. Haviland's "last words":—

1. That the districts having the *highest death-rates* from cancer among females were invariably associated with seasonally flooded areas traversed by, or in close proximity to, seasonally flooded rivers.

2. That geologically these *high mortality* districts were characterised by alluvium and subsoils of clays of every variety of age and formation.

3. That the districts having the *lowest death-rates* from cancer were situated on elevated land, where the drainage was good and the physical features of the country such as to preclude the possibility of floods; where rivers derived their sources and where, in fact, they are not fully formed.

(4) That geologically these *low mortality* districts were characterised by the eldest, palæozoic rocks, especially those of the carboniferous limestone periods, the liassic, oolitic, and cretaceous limestones.

The closing sentences of Mr. Haviland's intensely interesting paper run as follows:—"Thus at the end of this brief sketch of the medical geography of cancer we find ourselves asking the same question that rose to the lips of my audience in November, 1896: 'How is it that limestones are always associated in England and Wales with the *lowest* mortality from cancer, and *flooded clays* with the *highest*?' This question still remains unanswered, and will still so remain until the subject is taken up in earnest by the medical profession; for it is a field

I find after thirty years of working in it, that cannot be made to produce fruit without the toil of many labourers. When the above question is answered light will begin to fall on the cause of cancer.' It is a most refreshing thing to find this veteran statistician placing his figures at the disposal of his fellow-practitioners, modestly admitting his inability to draw sure and certain conclusions from them, and encouraging other workers to supplement his labours so that some determination on a most important question may be reached.

Let us turn to Mr. W. Roger Williams' most interesting work on "Diseases of the Breast," published in 1894, a work evincing an infinity of statistical learning. It is a model of how research by statistics should be employed in which figures are fairly handled and deductions prudently made. Furthermore, it is a mine for all those to dig in who are interested in the question of cancer. Mr. Williams thinks there is much to be said in favour of the opinion that in this country cancer is specially prevalent in flat, low-lying, fenny districts; noting especially Cambridgeshire and the adjacent counties of Northamptonshire, Huntingdonshire, and Bedfordshire. He observes, however (taking his figures from the Registrar-General's Forty-seventh Report), that all low-lying and seasonally flooded districts have not a high cancer mortality. The very large area drained by the Severn and its tributaries, for instance, has throughout a low average mortality from this disease. In fact, as we shall see presently, his view of the cause of the increased cancer mortality is very different and is not geological at all.

One would very much like to enter into the question of cancer houses, but it is, perhaps, digressing too far from my subject, which really has relation to the disease as it occurs in the breast. Mr. Haviland, Mr. D'Arcy Power, and Mr. Law Webb, of Ironbridge, in this country, as well as certain French and German surgeons, have written papers on the subject of profound interest—indeed, almost terrible interest. Still more evidence, however, will have to be forthcoming to make a clear case, for the liability to fallacious deduction in such a subject is so serious that a great mass and weight of testimony in its favour will yet have to be produced.

CAUSE OF THE INCREASED CANCER DEATH-RATE.

Up to the present time while statistics have already cleared and are at this moment rapidly clearing up many points about cancer, nothing definite has as yet been furnished by them as to the reason of its increase. That being so, there is a fair and reasonable ground for the employment of the "impression" begotten of experience. For many years the more I have thought over this matter the more forcibly does the idea present itself to me that it may be due to the great increase in the amount of food consumed by the people of this country during the past half-century. At all events, this view is worthy of being argued. I think it was first put into my head a long time ago by Sir James Paget. I took to him a lady with incurable cancer. He gave her some directions, and one was that she was to eat as little as possible—to try and starve herself, in fact. His long experience had taught him that to starve the body as a whole probably meant starving the cancer locally. *Per contra*, if that be a correct notion, then cancer ought to be connected with well-nourished bodies. Certain it is that the disease has not appeared to me to affect the weakling, the tea-shriveled, mummy-like old maid, or the ill-fed, more than half-starved drunkard, who never has any money to spend on good food. Its most numerous victims are well-nourished persons, with plenty of beef and fat about them, and often with a fine, healthy colour in their cheeks. In summing up the

many operations I have done for cancer of the tongue, my recollection of the patients is for the most part of biggish, powerful men with, large strong jaws which were hard to saw through when sawing had to be done. The better the nutrition and the younger the patient the more deadly and rapidly growing is the cancer. Take what is termed a fine, "buxom" woman of thirty or thirty-five with cancer of the breast, and her chance of permanent cure, even by the most extensive of operations, is almost *nil*. It is true that cancer is uncommon in the young during the period of development of the body and of the functional activity of organs, so that in one sense it is a disease of "degeneration," but this has nothing to do with the good nourishment and muscular development of the body in middle life. Being assured in one's own mind that well nourished, well developed, healthy people are the most numerous victims of cancer, the question at once arises, Is the increase of cancer in any way synchronous with an increase of nutrient material—i.e., of food—throughout the country, and are people in consequence better nourished? There cannot be a doubt of it. Ever since the passing of the Corn Laws bread has been cheap and plentiful, while during the last twenty years the importation of animal food from other countries has been enormous. The increased wages and emoluments of all classes in this country have enabled them to purchase freely of the best there is to be had in the whole world of things to eat and drink. Our working classes fare admirably. Our better classes eat infinitely too much, especially of animal food partaken of at breakfast, lunch, and dinner. But for the athletic tendency of the age and the general passion for games and exercises which pervades all classes, this over stuffing must have proved very dangerous. I am pretty well convinced that when a man is over five-and-forty excess in food is perhaps worse for him than excess in drink. Apparently one of the results of too much nourishing food is the production of a widely-spread, second rate kind of gout of a different type from the acute and furious attacks produced in former days by the copious drinking of beer and port wine. Moreover, I think distinctly that it has also to do with the production of the cancerous diathesis. This is also the opinion of Mr. Roger Williams, who, while admitting Mr. Haviland's topographical statistics, cannot agree with him in his geological views, but inclines to think that cancer areas are also the areas where the people are best nourished. The stock answer to what may be called the Over-nutrition Theory is that vegetarians and rice-eaters are just as subject to cancer as gross feeders and flesh-eaters, and this statement goes on being very steadily repeated from one book to another. I am not prepared to admit this. Cancer is not so rife in Ireland, where feeding has been poor and very largely of a vegetable character, and where improvement in the living of the people has not proceeded *pari passu* with that in England. The Registrar-General's Report for the decade 1881-90 shows that in 1881 in England 1 death in 36 was due to cancer, and in Ireland 1 in 47, while in 1890 in England there was 1 in 28, and in Ireland 1 in 40. Ireland, therefore, does not rise to the level of England. Mr. Roger Williams has a most interesting chapter of facts in this connection. He tells that Billings, of the United States, showed that among the whites there were two cases to one among the blacks. From what can be learnt of the whole continent of Africa, that vast country enjoys a remarkable immunity from the disease, especially the Egyptian area and the Northern parts. At the Cape, cancer is common among the whites, but very rare among the natives. All through the tropics the disease is distinctly rare. In India the general opinion is that it is not common, and

that when it does occur neither the rice-eaters nor the meat-eaters are exempt. It is true that certain surgeons (McLeod, Hendley, and Lawrie notably) hold the opposite opinion, but I notice that their experiences are drawn from hospital work almost entirely, and refer chiefly to the number of operations occurring in large hospitals. This seems hardly a sound argument. All that it proves is that a number of cases of cancer come into large hospitals and consequently that in a huge country there must be many cases of cancer. But, if statistics are to be of any avail, the proportion of cases to the actual population is absolutely necessary to make any fair deduction. It is like the death rate from snake-bite. To an Englishman who never sees such a thing the sum total of these seems appalling. It is not till one takes the proportion to the astounding population of India that the insignificance of the loss of life becomes apparent. If there were no knowledge of the exact population of Lancashire, and if a person were to walk round the wards of the Liverpool Royal Infirmary and estimate the cancer mortality of the county from the number of cases found in these wards, his view of the prevalence of the disease would be a most alarming one.

At this moment the Massachusetts State Board of Health is instituting an inquiry into this question. Its circular states that "Every year there is an increase in the reports to the State of the number of deaths from cancer, even when allowance is made for age and greater population. By some it is alleged that this is due to an increase of the disease itself; by others that better diagnosis and more careful registration will account for it. Furthermore, the infectious nature of this disease, caused by a possible parasite, and its contagiousness have been strongly urged." I believe that the great general increase of cancer is for the most part admitted, and that Dr. Newsholme's idea that it is not real but only an apparent increase, due to better knowledge and more accurate registration of the disease, is entirely erroneous. But, even were we to admit his views, it would not account for the fact that, during the past thirty years, the comparative cancer mortality of the sexes has altered in a most singular manner, so that whereas the disease was formerly more prevalent among females, it has now become more prevalent among males, and is becoming increasingly so.

Now, do drunken habits account for more cancer?

I am certain that confirmed drunkards are not more liable to it than other people. Besides, drunken habits are rather diminishing than increasing. Does syphilis account for it? I have never been able to trace any connection between that disease and cancer whatever. It is true that leukoplakial bald patches and specific surface ulcers of the tongue and mouth are places where epithelial cancers arise, but they do so, not in virtue of any special syphilitic taint, but just as they arise from irritation of any kind, as from a sharp-edged tooth. Mr. Williams, out of 165 female breast-cancer patients, did not find a single one of immoral character. Do bad water, bad housing, and bad sanitary arrangements account for it? This is impossible, for in nothing have we improved so much as in improved sanitation; in improved water supply, drainage, housing, and clothing. Will increased nervous tension from our rapid existence, due to the development of steam and electricity, account for it? It would seem reasonable to suppose this likely to produce all sorts of nervous troubles and arterial or cardiac degenerations, but not cancer. Is it due to the fact that there is a great saving in the early periods of life, and that more people live into what may be called the cancerous age? The Registrar-General's statistics show that the number of persons of twenty-five years of age and upwards, out of every million living persons, was just the same in the

decade 1881-90 as in the decade 1871-80. There has, therefore, been no increase in the proportion of persons who live into the cancerous age.

What great change, then, has taken place in the national life? Richer and more abundant food. You will note particularly that it is the male who eats the heavy food in ever-increasing quantities, while the female remains much as before in her eating, and note along with this that it is men now who suffer most severely from cancer, and not women as formerly. Again, in all England the most tainted places are London, the Thames Valley, and the counties adjoining the metropolis, where the most luxurious habits and the best living prevail, and it has been pointed out that, even in the capital itself, the parts where those in easy, comfortable circumstances, who are supplied with more than the necessities of life abide, show the highest mortality. It is curious to note that amongst the very highest mortality rates for occupations are those which include commercial travellers, coachmen and grooms, merchant seamen, maltsters, brewers, innkeepers, butchers, and plumbers. Most of these certainly are persons likely to eat and drink abundantly, and not take too much exercise—persons who live well and don't work off their spare products. Singularly enough, doctors figure low in the list.

In conclusion, let me quote Mr. Moore's statement, made many years ago, that "cancer is eminently a disease of persons whose previous life has been healthy, and whose nutritive vigour gives them otherwise a prospect of long life."

(To be continued.)

THE CAUSES AND TREATMENT OF MOVABLE KIDNEY. (a)

By MANSELL MOULLIN, M.D. Oxon., F.R.C.S.,
Surgeon and Lecturer on Surgery at the London Hospital

AFTER thanking the President and the Fellows of the Hunterian Society for inviting him to deliver one of the Hunterian lectures this year, and mentioning his reason for selecting movable kidney as his subject, the lecturer proceeded to explain why the presence of a movable kidney was so often diagnosed during life, and so rarely found after death. A distinction was drawn between movable kidney and floating kidney, in which there is a live mesonephron; and it was pointed out that although the kidney might push the peritoneum in front of it like a hernial sac, or even possibly insinuate itself between the layers of the ascending or the transverse mesocolon, neither of these could be regarded as constituting a mesonephron, a structure which it was almost impossible to explain on the ordinary view of the development of the peritoneum. The relation of the kidneys to Cunningham's subcostal plane was then described, and the lecturer proceeded to demonstrate that the generally accepted view that the kidneys were fixed organs was incorrect. During life the kidneys, with all their anatomical relations undisturbed, normally possess a range of movement estimated by Alberran at from three to five centimetres. The movement is especially evident when the kidney is exposed through an incision in the loin. This makes it more difficult to define what should be called a movable kidney. Kendal Franks holds that the extent of surface which can be felt beneath the ribs is the best criterion. A much more satisfactory test, however, is the failure of the kidney to reascend on tranquil expiration (coughing or straining is not fair) when the patient is

(a) Abstract of the Hunterian Lecture delivered before the Hunterian Society, February 24th, 1900.

standing erect, and has driven the kidney down by forced inspiration. I look upon this as sufficient, even if the kidney only comes down low enough to enable its inferior extremity to be felt. If, on the other hand, it retains its normal relation to the diaphragm, so that the movement of the one follows that of the other, I do not regard it as unduly movable, even if half of the organ can be felt.

The kidneys are invested by what has been described by Luckerbendl and Gerote as the perirenal fascia. This is a development of the subperitoneal tissue, strengthened upon the left side, where it lies upon the ventral surface of the kidney, by some fibrous bands, which Luckerbendl has shown to be the remnant of the fusion of the descending mesocolon with a primitive parietal peritoneum. The corresponding strands on the right side, owing to the different position of the colon, stand in no relation to the kidney. The fascia consists of two layers, anterior and posterior. These are united along the external convex border of the kidney, but are quite separate on the inner side and below. The anterior layer passes across the great vessels, and becomes continuous with the anterior layer of the opposite side. Below, both layers are lost in the subperitoneal tissue. Together they form an investment for the kidney, loosely attached to it by connective tissue and fat, open on the inner side and below. Like the recess in which the kidney lies, this fascia offers no resistance to movement of the kidney downward and inwards. The normal movements of the kidney during respiration, and when the body is raised from a horizontal to an erect position, take place inside this investing fascia.

Immediately around the kidneys, inside this perirenal fascia, is a large amount of fat which differs in colour and consistence from the ordinary subperitoneal fat, and which must be regarded to some extent as a special structure having a special function. It is but slightly developed until the eighth or tenth year, and is so soft and delicate in structure that it appears to be much more suited to facilitate the movements of the kidney than to check them. This deposit is especially thick in the posterior surface, and opposite the hilus, for on this surface the perirenal fascia is closely attached to the transversalis fascia, and this in its turn is firmly blended with the muscles beneath. In front there is comparatively little, for here the anterior layer is more loosely attached to the peritoneum, and both are movable. Atrophy of this fat has been noted in some cases of movable kidney, but much more often is abundantly developed, and has to be stripped off in the operation for suturing the kidney in place.

Running through this fat are some stouter strands of fibrous issue, which pass from the fascia to the renal capsule. They are best developed above, and opposite the hilus, but there are a few below. In cases of nephroptosis these are either torn or unduly stretched. Wolbon and Delitzin have shown that they are not strong enough to support the weight of the kidney, and they believe that their chief function is to maintain the normal shape of the kidney, and the relative position of its different parts. If the upper ones are divided, the upper segment of the kidney, according to these observers, falls forwards upon the lower. Potain has described this displacement, which he calls anteversion of the kidney, and it is said that sometimes it causes very severe symptoms, from the way in which it presses upon the neck of the gall-bladder and the bile-duct. However this may be, Newman showed a long while ago that if the abdomen is opened while the body is suspended in the erect position, the kidneys, which are already at their lowest normal point, fall much lower, even though these bands are uncut. Neither the fascia nor the fat is capable of

maintaining the kidney in position when the influence of the abdominal pressure is removed.

The same may be said of the peritoneum. This is stronger on the right side than the left, owing to a special fold described by Jonnesco; but the kidneys glide behind it, and it is so easily displaced, even on the posterior wall of the abdomen, that they have no difficulty in pushing it before them. The surrounding organs check the movements of the kidneys and support them, but the kidneys are not in any way tied down or fastened by ligaments, like, for instance, the splenic flexure of the colon.

Kendal Franks described the kidneys as maintained in position by the combined pressure of the liver, acting from above and in front, and the colon, acting from below and in front. But the liver and the colon, so far as intra-abdominal pressure is concerned, cannot be regarded as independent agents. Together with all the other organs enclosed by the peritoneum, they form one soft elastic mass pressing against the kidneys. If any one of the organs that form this mass changes in position or consistence, the rest, so long as the peritoneal cavity is unopened, compensate for it at once. There is no independent action until air has been admitted into the peritoneal cavity.

Glénard regards mobility of the kidneys as merely one of the phenomena of enteroptosis; but in the vast majority of cases in which the right kidney is movable there is no displacement of the other viscera. When enteroptosis does occur, so that the liver rotates and the intestines sink, movable kidney may follow, owing to the disturbance of the intra-abdominal pressure. Even this, however, will only happen if there is at the same time defective development of the lumbar recesses.

The kidneys are maintained in position partly by the pressure in the intra-peritoneal space, partly by the way in which they fit into the lumbar recesses. Neither of these is sufficient without the other. Woldon and Delitzin in particular have drawn attention to the importance of the shape of the lumbar recesses. This is best shown by taking plaster casts of the posterior wall of the abdomen while the body is suspended vertically. In the male they are deep, narrow, and pear-shaped, with the narrow end below. In the female, owing to the greater width of the pelvis, they are shallow and more cylindrical, and the difference in shape is almost always more marked upon the right side than upon the left. This I believe to be due to a slight degree of torsion of the lumbar spine. In right-handed people there is usually a slight convexity towards the right in the dorsal spine. This entails an equivalent convexity towards the left in the lumbar region; and this, in its turn, necessitates a slight degree of rotation. The left transverse processes rotate backwards, and deepen the lumbar recess upon that side. The right rotate forwards, and make the lumbar recess proportionately more shallow.

In a very large number of cases of movable kidney there is definite flattening of the right lumbar region. This, of course, cannot possibly be due to absence of the right kidney. Abdominal nephrectomy does not cause it. It really means that the vertebrae have rotated slightly, and is an indication of the cause of the displacement of the kidney, not a consequence of it.

The width of the lumbar recesses is one of the penalties which have followed the assumption of the erect attitude. If the history of the development of the renal organs in the race, as well as in the individual, is worked out, it is seen that originally they were distributed over the whole length of the head and body; and that by degrees, as their function became more specialised, they became concentrated together, until in their most perfect form they con-

stitute a pair of organs, which, in the quadrupedal mammal, are placed in a position of the greatest possible security. They lie close to the spine immediately under the antecentral vertebræ, almost in the central axis, around which all movement of the trunk and limbs takes place. They are buried in two deep and narrow recesses, protected by the lower ribs, and resting upon a horizontal sheet of fascia, which in its turn rests upon the peritoneal viscera. The slight degree of backward and forward movement which is necessitated by the action of the diaphragm, takes place without the least risk. But with the assumption of the erect attitude the greater portion of this security is lost. The backward and forward movement is altered to movement upwards and downwards, in the direction of the line of gravity. The peritoneal viscera and the supporting fascia lie in front, and not below. The lumbar recesses, instead of being deep and narrow, become broad. The convexity forwards of the lumbar spine helps to make them still more shallow. The pelvis, especially in the female sex, becomes wider, so that the lower end of the recess becomes more open; and then the development of right-handedness causes the transverse processes of the lumbar vertebræ, which lie under the floor of the lumbar recess, to rotate ever so little. From a position of the greatest safety, the kidneys are placed in one from which all security is gone; and it is not to be wondered at that comparatively trivial causes—an increase in the weight of the organ without a corresponding increase in the bulk, a sudden violent jerk, or a great lowering of the intra-abdominal pressure—can increase their normal range of mobility. The wonder is, not that movable kidney occurs, but that it does not occur more often.

This will account completely for the peculiar clinical distribution of movable kidney. It is certainly hereditary, and common. It is present in women much more often than it is in men; and in women who have borne children more often than in those who have not. And it is much more common upon the right side than upon the left. None of the other reasons which have been assigned for this, such as the weight of the liver or the length of the renal vessels, deserve consideration.

(The lecturer, after detailing the different methods of treatment which have been advised, proceeded.)

The choice lies between wearing an abdominal belt and nephrorrhaphy. In my experience it is only in the milder cases that the former succeeds, and then it must be combined with massage and exercises calculated to strengthen the abdominal muscles. A belt braces the viscera together, and so steadies the displaced organ, but it cannot press the kidney back into its place, or retain it there after it has been reduced, if the patient stands upright and takes a deep breath.

Pads are useless. For all cases in which there is manifest deformity of the lumbar region associated with movable kidney, or in which there is real distress, even if the mobility strains no higher degree than the anteversion of Potain, I never hesitate to recommend nephrorrhaphy. In the former case it is advisable in order to save the kidney from hydro-nephrosis and other troubles. In the latter I believe it to be the most certain method of giving relief. I have never known it fail when properly carried out, if the symptoms have not already lasted so long as to produce an indelible impression upon the patient's nervous system.

The second reading of the Bill for the Registration of Midwives, which was down on the list for Wednesday last, was not reached.

THE SURGICAL TREATMENT OF TUBERCULOUS KIDNEY.

By DR. KÖNIG,
of Berlin.

A FEW decenniums ago the subject of tubercle of the kidneys was almost unknown, and it hardly ever occurred to the surgeon to consider the matter, only tubercle of the bladder being thought worthy of special attention. Once, however, it had been recognised that so-called catarrhs of the bladder were frequently tuberculous, it gradually came to be understood that these vesical catarrhs were in reality tubercle of the kidney. An unprejudiced consideration of the question dates from Simon's investigations, and these showed that only a small quantity of functionally active kidney substance was necessary for the maintenance of life. It was only from this period that operation could be thought of. But the idea of removing tuberculous kidneys was not at first grasped, and when this came to pass it was generally the result of an error of diagnosis. In the commencement of the eighties, however, tuberculous kidneys were deliberately removed, and in 1883-84 statistics on the subject were published.

In renal tuberculosis two different conditions must be carefully distinguished. In the one form isolated foci of disease are found in the gland substance, either near the cortex or nearer the pelvis, but not communicating with the latter. As a rule there are one, two, or three patches with a tendency to caseation, or to the formation of phthisical cavities. The second form is the pyelitic, arising from the bursting of the glandular form into the pelvis of the kidney, or from an ascending tuberculosis. These two forms present very different symptoms. The first, the so-called hæmatogenous form (although it is not really known whether it is hæmatogenous or urogenous), is difficult of diagnosis, and can but rarely be controlled. In two of the speaker's cases it passed into the pyelitic form, in one case after gonococcal infection, the other in consequence of renal irritation set up by inhalation of turpentine. The first form had, therefore, a more theoretical interest. The assemblage of symptoms of tuberculous pyelitis is characteristic even without proof of the tubercle bacillus, which indeed it is not always possible to obtain. The symptoms indeed are those of chronic catarrh of the bladder, with certain peculiarities: gradual illness, with turbid urine, almost always frequent desire to micturate with pain in the urethra. If to these is added the typical kidney pain, of variable intensity and form, the diagnosis is tolerably certain. The diagnosis may be determined from the urine also; it is turbid, the sediment contains epithelium partly from the pelvis of the kidney and pus. Blood in every form is quite common, and it sometimes happens that the quantity is considerable, amounting to absolute flooding, especially at the commencement of the disease; often, especially in women, the kidney tumour can be felt. This group of symptoms justifies a diagnosis of tuberculous kidney, even when the bacilli cannot be detected. As a matter of fact they are only rarely to be found. Later on the bladder symptom becomes more pronounced owing to the presence of ulcerations, which, associated with swellings at the opening of the ureters, can often be seen. The patients are emaciated and feeble, and are markedly anæmic.

Medicines obviously cannot effect a cure. At one time the idea of extirpating the tuberculous disease alone was put forward. Max Wolff had recommended resection of the kidney, but practical experience was wanting. Out of seventeen kidneys extirpated there

was not one in which resection was possible, there was everywhere disease, and the pyelitis so bad that there could be no question of resection. Exploratory incisions might certainly be made in the kidney, and pieces might be excised without endangering life; but simple incision of the kidney and its pelvis, as recommended by Guyon can do no good.

The only possible operation is the extirpation of the diseased organ in its entirety. Of course the other kidney must be present, and by careful examination this can be determined. In the horseshoe kidney we have only one kidney, but as a rule it cannot be palpated, and it does not play the part of a solitary kidney. In the case of a boy the author had removed one part and the boy recovered. The solitary kidney is more difficult of diagnosis. With regard to this we have the following indications:—(1) The testicle is often absent on one side. (2) On cystoscopic examination if only one ureter is found there is but one kidney. Then, again, the healthiness of the other kidney is a difficult question. It has first to be decided which kidney is diseased, and this is shown by observing the flow of turbid urine out of a ureter. The cystoscope is not of such value as regards the second kidney, for it can only show that clear urine comes from the corresponding ureter, and that is not a certain proof that the organ is healthy. Even catheterisation of the ureter does not afford certain proof, as was shown by an error into which the master of catheterisation fell. Besides, the operation is not free from danger, for it may set up ascending tuberculosis. In short, there are no certain means of diagnosing whether the second kidney is or is not healthy.

In twenty of the author's own cases there had been an error of diagnosis in two. In one case the pyelitis was simple, although the lungs were tuberculous, and in the other smegma bacilli led to the error. Three cases died of uræmia. One was a case of caseous atrophic kidney, and in the other two there was necrosis of the epithelium, caused by chemicals, chloroform, or sublimate. No such cases occurred later on.

Another question arises: Can we operate when the other kidney is diseased? According to Tuffier's experiments the question can be answered in the affirmative. Simultaneous disease of the bladder, the testicles, or prostate is not a contra-indication. In deciding whether to operate or not we must always bear in mind that the patient's condition is so pitiable that he cannot last many weeks without operation, and we must risk something.

He had operated on eighteen cases, twelve women and six men, of whom three died in connection with the operation, three of continuing general tuberculosis three to nine weeks after operation, eleven recovered, and one case was too recent to consider. One was operated on in 1883, was quite healthy, and was about to marry. The second, a girl operated on nine years ago, was now a blooming (*blühendes*) maiden. The third was a labourer, operated on six years ago, was now so well that his sick pay had been withdrawn. Three other cases had been operated on two to two and a-half years (two of them were shown, and also a young woman and a young man operated on about a year). One girl with disease of the bladder as well and advanced kidney disease got quite well, and lived seven years, dying in childhood. Some of the cases recovered perfect, or at least comparatively good health, being rescued by the operation from almost certain and speedy death.

From his own observations the speaker summed up as follows:—1, Localised tuberculosis of the kidney can rarely be recognised; 2, tuberculous pyelitis on the contrary always; 3, absolute certainty that the other kidney is healthy cannot be obtained, but we

are still compelled to operate; 4, resection can only exceptionally be resorted to, extirpation being the normal operation, since it brings about a cure in a number of patients, and in many others prolongs life if nothing more.

NOTES FROM CURRENT MEDICAL LITERATURE.

FORMALIN AS AN APPLICATION TO CANCEROUS ULCERS.

DR. A. RAVOGLI reports wonderfully good results (*Virg. Med. Monthly*) following the use of a five per cent. solution of formalin to cancerous and rodent ulcers. Formalin has been gradually more and more used in surgical practice since its introduction in 1886. It is, however, a painful application, and before being applied to ulcers some local anæsthetic should be used on the part.

MENORRHAGIA.

Novo. Montcell. Med. recommends the following:—

Salpirine,	10 grammes;
Potass. Bromide,	10 grammes;
Ext. flu. Viburn. Pum.,	20 grammes;
Distilled Water,	120 grammes;
Cognac Brandy,	20 grammes;
Syrup of orange peel,	20 grammes.

Mix. One teaspoonful for a dose. The mixture is to be commenced five days prior to the change. On the fifth day prior to the change, a dose is to be taken at night; on the fourth and third days a dose is to be given night and morning; the second day a dose is to be taken morning, midday, and evening; and on the following three days a dose is to be taken four times each day.

TROPICAL DYSENTERY.

Decoction of Simaruba,	170 grammes;
Cognac Brandy,	10 grammes;
Mucilage of Salep,	10 grammes;
Tincture of Opium,	1 grumme;
Syrup of Orange Peel,	25 grammes.

Mix. One tablespoonful every two hours.—*La Semaine Médica.*

JANOCOL.

Janocol is a combination of gelatine and tannin. It occurs as a grey powder, odourless, tasteless, and almost insoluble in water, and sparingly soluble in dilute acids. Alkaline solutions dissolve it readily. Intestinal juice dissolves and decomposes it, liberating tannic acid. It is recommended as an astringent in acute and chronic enteritis, and in intestinal diseases of children.—*La Semaine Médica.*

PRURITUS.

Dr. Castel (*Gaz. Med. de Strasbourg*) refers to the good results he got in cases of pruritus from the use of lactic acid, in doses of from six to twenty drops twice a day. The effect is equally good in those cases of eczema of the buttocks occurring in young children with diarrhoea. With the lactic acid in cases of eczematous troubles he uses the following ointment:—

Salicylate of Methyl,	2 grammes;
Oxide of Zinc,	20 grammes;
Vaseline,	20 grammes.

Mix.

KINEWINE.

Kinewine (*La Progrès Médical*) is the name given by M. Moncom to the glycerophosphate of quinine which he introduced to La Société de Pharmacie.

It is obtained by neutralising the acid glycerophosphoric by quinine, by mixing and mutually decomposing a solution of a salt of quinine and the glycerophosphate of lime. The quinine salt occurs in fine needle-like colourless crystals; it is odourless; bitter, but its bitterness is less than that of quinine sulphate and more agreeable.

Kinewine is slightly soluble in water, more so in boiling water than cold. At a temperature of 15 degs. C. water dissolves one-half per cent. and one-and-a-half per

cent. at 100 degs. C. It is soluble in cold and boiling alcohol, insoluble in ether, and freely soluble in glycerine.

The salt is very stable remaining unchanged in the presence of the glycerophosphate of lime, and is not altered by heat. Its composition is given as

It contains 72.6 per cent. of quinine, and 19.2 per cent. of acid glycerophosphoric.

The therapeutic study of the chemical, made by M. Gilbert, shows that the new compound is equally good as a febrifuge as the sulphate of quinine, and that it is more easily assimilated, and having the same richness as quinine it is prescribed in the same doses.

DIABETIC FOOD.

In a long article (*Bull. Gen. de Therap.*), M. Mossé, professor of clinical medicine at Toulouse, concludes that in the diabetes of medium severity, particularly if associated with joint troubles, bread made of potato flour is much more suitable than bread made of wheat or other cereals.

JAUNDICE.

M. M. Lenez and Schneider publish (*Le Progrès Medical*) the case of an active attack of jaundice, marked by coma, convulsions, and scanty urine, which they treated with large injections of artificial serum, which they sent into the cellular tissue of the right iliac fossa, and repeated the injection in six hours.

A few hours afterwards the convulsions ceased, consciousness returned, and the patient had a copious flow of water and a brisk purging. The following day the injections were repeated, and some days afterwards the patient left hospital quite well.

TUBERCULOUS LARYNGITIS.

M. Lacroix, at a meeting of the Academy of Medicine, Paris, reports favourably of the use of antiseptic inhalations in cases of tuberculous laryngitis. He vapourises a mixture of menthol, bromoform, and formaldehyde. He has found the inhalations to have not only a soothing effect and to diminish the blood-shotness of the mucous membrane, but also to cause the healing of ulcers.

He bases his conclusions on an experience of three years.—*Le Progrès Medical*.

INITIAL TUBERCULOSIS OF THE RECTUM.

In a paper read before the Clinical Society of Maryland, Dr. Earle (*Vir. Med. Sem. M*) reports three cases of acute tuberculous proctitis studied at autopsy at Bay View. He found the bacilli in the infiltrated mucous membrane, where there was as yet no breaking down, and where the small cell infiltration was the only pathological condition.

RUPTURE OF THE URETER.

Le Progrès Medical reports the case of a man, 18 years old, who got a blow in the left side of the abdomen. One month after the accident the left side of the abdomen became much larger than the right, the increase in size was due to a collection of fluid which extended from Poupart's ligament to the fourth intercostal space. In the interval of a month and a half the collection of fluid was aspirated six times, and thirteen litres, and eight hundred grammes of fluid drawn off. The patient made a good recovery.

BISMARCK'S BRAIN.

The cerebrum of Prince Bismarck is said (*Rev. de Ther. Medicales*) to have weighed 1,807 grammes. The average weight of the European brain varies from 1,350 to 1,400 grammes. Of illustrious men whose cerebrums were weighed we find that of Dante to weigh 1,470 grammes, Schiller's weighed 1,596, Kant's 1,624, Byron's 1,792, and Cuvier's 1,828. On the other hand the brain of Gambetta was not above the average weight, and that of Shelley was distinctly below it.

Brains may, however, be so warped by hereditary influence or other, that the possessor gains notoriety

from crime only. Of such was Vacher, who assassinated some nineteen persons, and was guillotined on the 31st of December, 1898. His brain weighed 1,500 grammes, and the cerebellum 76 grammes; withal the great weight of evidence favours Dr. Marro's views: that incendiaries and murderers yield the largest proportion of individuals with defective intelligence.

Like the savage, the criminal is lacking in curiosity, the foundation of sciences, and one of the very highest acquisitions of man.

Clinical Records.

SOME SURGICAL CASES ILLUSTRATED BY RADIOGRAPHS. (a)

By NOBLE SMITH, F.R.C.S.Ed.

I AM enabled to lay before you some instances of the advantages of radiography in surgery. The first case is one of Potts fracture. Nine months after the accident the patient was hardly able to get about. A radiograph shows that the foot was so much displaced outwards that the weight of the body was transmitted through the centre of the tibia and impinged upon the inner edge of the astragalus, thus pushing the foot towards a valgus position.

The fibula, which had been fractured diagonally, had united with much thickening, making it impossible to replace the foot in a better position without operation.

The fibula was then cut through with a chisel, and the tendo Achillis divided, when the foot was easily placed in a much better position. The patient felt immediate relief from the aching she had previously suffered. A week after the operation movements of the joint and massage were commenced, and this treatment gave the patient great comfort. A few days later, she was able to stand up on the lame foot without difficulty. At the end of six weeks she was able to walk about far more comfortably than she had previously been able to since the accident. It is doubtful if this operation could have been carried out so successfully without the radiograph.

The next case is of a child, $\text{æt. } 2\frac{1}{2}$, who was thought to be affected with a bowed leg. I noted, however, that one leg only was affected, and that the inner malleolus was distinctly higher than natural, and that the child evinced pain upon interference with the limb. I therefore suggested a radiograph. This showed clearly a fracture of the tibia $1\frac{1}{2}$ ins. above the ankle-joint. It was cut down and the bone straightened, and the child made a good recovery.

I have also derived considerably assistance from radiographs of congenital dislocation of the hips, coxa vara, and knock-knees.

Dislocation of Cervical Vertebrae.—The following is a very interesting radiograph of the case of a lady who fell 80 ft. down some rocks in the Island of Sark, and although she was not killed she sustained a very severe shock and great bruising as well as severe cuts, the nose and one ear being much damaged. After some weeks' rest she began to get about again, and then suffered from pain and stiffness in her neck; also attacks of giddiness came on and so affected her that she would suddenly fall down, and especially when she placed her hands above her head in attempting to dress her hair. Upon examination of the spinal processes of the cervical vertebrae I detected an angular bend centred between the fifth and sixth cervical vertebrae. A radiograph clearly indicated a partial displacement between these two vertebrae. The patient was placed under ether, and firm extension made upon the head. Some adhesions were at first felt to give way, and after more force had been applied a slight gliding movement was felt in the neck. It was then found that the vertebrae occupied their natural straight position. The acute symptoms of the displacement have not been felt since the operation, and her mother has written to say that her daughter is now practically quite well.

(a) Read before the Windsor Medical Society.

Transactions of Societies.

ROYAL ACADEMY OF MEDICINE IN IRELAND SECTION OF ANATOMY AND PHYSIOLOGY.

MEETING HELD FRIDAY, FEBRUARY 2ND, 1900.

The President, Professor W. H. THOMPSON, M.D., in the Chair.

PROTAMINES AND THEIR CLEAVAGE PRODUCTS.

The President read a paper on Protamines, which or hydrolytic cleavage yield mainly hexone bases—viz. arginine, with histidin and lysine in some cases, and gave the result of experiments on anaesthetised dogs.

Prof. Coffey, Dr. W. Smith, and Dr. Dawson discussed this highly technical subject, and the President replied.

MODEL OF THORACIC AND ABDOMINAL VISCERA.

Dr. PATTEN, in the unavoidable absence of Professor Cunningham, exhibited for him a model of the thoracic and abdominal viscera from behind, which had been prepared primarily to exhibit the form and relations of the spleen.

SIMPLE FORMS OF MUCOUS GROWTH.

Professor COFFEY showed sections to illustrate the formation and manner of development of the small racemose glands of mucous membranes taken from the oesophagus of snakes.

A SERIES OF HUMAN EPIPHYSES.

Dr. KNOTT exhibited a large series of human bones, all of which presented non united or partially united epiphyses. The series illustrated the development of the limb bones, the pelvis, scapula, sternum, clavicle, metacarpals, metatarsals, phalanges, vertebrae, ribs, and a large number of cranial bones. Among the specially interesting items were an atlas which was obtained in process of ossification from at least nine centres, and an ulna which presented a small epiphysis on top of the ordinary epiphysis for the upper end of the olecranon process, a centre of ossification which, up to this, seems to have completely escaped the notice of anatomists. When the elbow-joint was bent this supernumerary epiphysis presented a striking resemblance to a diminutive patella turned upside down.

Professor BIRMINGHAM referred to the great difficulty of procuring specimens to show the epiphyses, and said he was not satisfied that the additional centre for the olecranon was constant.

THE FORM AND POSITION OF THE STOMACH.

Professor BIRMINGHAM gave a lantern demonstration of the form, position, and relations of the stomach as seen in bodies which have been hardened by intravascular injections of formalin. The chief points upon which he dwelt were:—That the empty stomach was contracted, not collapsed, its pyloric portion resembling thick-walled small intestine; its cardiac portion rounded, but attenuated; its surfaces looking, the one up, the other down, and its long axis nearly horizontal. In this condition it rests on the "stomach bed," occupying only the lower part of the "stomach chamber," the upper part of this space being occupied by the great omentum and the transverse colon, which double up over the empty stomach and lie between it and the diaphragm. The large, flattened, and collapsed stomach, with anterior and posterior walls in contact, usually described and pictured, is not found in the hardened body. Three stages are recognised in passing from the empty to the distended condition. In the first the fundus and cardiac portions were expanded, the pyloric portion remained contracted, and the lesser curve sharply bent as in the empty state; in this stage the stomach resembles a Florence flask, strongly bent at the junction of neck and body. In the second stage the cardiac portion is further expanded, and the pyloric portion opens out, but the junction between the two is distinctly marked. In the third stage there is an enlargement of all the axes of the organ; the distinction between pyloric and cardiac parts is almost lost; the pylorus is carried an inch or two to the left of the middle line, and the antrum pylori is developed. But in all these changes there is no rotation

around the long axis of the organ, with a raising up of the great curvature, &c., as commonly described. The distended stomach lies obliquely, its long axis running from the fundus, not vertically, as we have been taught in recent times, but inwards and downwards, at an angle of about 40-45 degrees with both the horizontal and mesial planes. The various views expressed by the author were illustrated by photographs of hardened bodies, and also by a series of hardened stomachs, showing the various stages of distension, and showing the sphincter action of the diaphragm on the lower end of the oesophagus.

Dr. PATTEN remarked that as one ascended the scale from the lower animals there was an increasing tendency for the long axis of the stomach to become somewhat oblique, while, at the same time, the transverse colon became more distinctly marked, and he suggested that the transverse colon was the principal factor in determining this change in the position of the stomach.

Mr. TAYLOR pointed out that the beginning of the small intestine occupied a deep recess in the left region of the abdomen below the stomach, from which it is separated by the transverse meso-colon, only, as just pointed out by Professor Birmingham. If the meso-colon be torn through, and this portion of the intestine connected to the under surface of the stomach, the result will be that the intestine will be connected to the lowest part of the stomach, and thus gravity will assist the passage of the food into the intestine.

Professor BIRMINGHAM, in reply, thought the obliquity in the human stomach was probably due to the wide thoracic framework. In a female subject with a very constricted waist, the stomach (which he exhibited) lay almost vertically on the left side of the vertebral column. Regarding the question of the existence of a valve at the cardiac orifice, he thought that little reliance could be placed on observations made on dried specimens. The return of food from the stomach into the oesophagus would be amply guarded against by the contraction of the muscular fibres of the oesophagus and the crura of the diaphragm, as illustrated by a specimen exhibited.

VISCERAL ANATOMY OF GIBBON.

Dr. CHARLES J. PATTEN brought forward a communication dealing with the visceral anatomy of the gibbon. The paper dealt principally with the form and position of the thoracic and abdominal organs. Many of these (lungs, heart, stomach, spleen) very closely resembled those of the human subject, as one might anticipate in such a highly developed anthropomorphous ape. The specimen was first hardened in formalin to ensure the contour of the viscera.

The Section then adjourned.

LIVERPOOL MEDICAL INSTITUTION.

MEETING HELD THURSDAY, FEBRUARY 22TH, 1900.

Mr. W. T. THOMAS, F.R.C.S., Vice-President, in the Chair.

CASES.

MR. R. W. MURRAY showed a patient upon whom he had performed the operation of tarsectomy for double club foot.

Dr. ALEXANDER related two cases in which he had removed foreign bodies from viscera, and showed the specimens, (1) pieces of coal and pebbles removed from the vagina, (2) a piece of slate pencil removed from the male urethra.

RECENT OPERATIONS ON THE STOMACH.

Mr. RUSHTON PARKER read a paper on this subject comprising fifteen cases, of which eight occurred in the last six months, and twelve in the year. Four were "gastrostomies" in men, for carcinoma of the oesophagus, the operation being that known by the names of Hahn, Franck, and Albert. Two of the patients died within six months of acute phthisis, one in six days of bronchitis, one in three months, suddenly, of syncope. He considered the procedure in suitably selected cases of

value, but probably the least satisfactory of the temporary operations on the stomach. Four were "gastro-enterostomies," three in men and one in a woman. The symptoms all pointed to carcinoma, and although a tumour was felt only in two, in all a growth was found, which was either too firmly fixed or surrounded by secondary deposit to permit of removal. Two are still doing well, the others getting worse, in one the tumour is increasing, and is undoubtedly cancer, whilst in the others no microscopical verification has been made, and between carcinoma and gumma there is no means of being certain in the examination by eye and hand alone. The operations were well borne, and the healing rapid. No adventitious appliances were used. The nearest piece of jejunum was attached to the lower part of the stomach, an incision 3 ins. long being made in the axis of each viscus, and continuous silk sutures used, are set through mucous membrane, another through peritoneum. The operation quickly admits of satisfactory feeding, and although only required for temporary purposes, may now and then give permanent relief in the event of suspected carcinoma proving to be non-malignant. Two cases of excision were shown, one a woman, *æt.* 37, for malignant disease (ascertained microscopically) to the left of the pylorus, still in good health without any sign of recurrence after two years; one a man, *æt.* 49, for whom pylorotomy was done a year previously for a tumour thought to be malignant, but at the operation regarded as gummatous, and proved microscopically to be so. Three cases of pyloroplasty were discussed, two for contracted pylorus due to gastric ulcer, the other for ulceration (probably syphilitic) contracting the right half of the stomach.

Two patients were shown after perforation of gastric ulcer, one, a chronic perforation with limiting adhesions to the liver necessitating complete section of the stomach near the cardiac end before suture; the other a perforation operated upon within six hours of the accident. Hour-glass contraction of the stomach existed to the diameter of an inch, with the perforation in front of it. Free incision of the contraction right and left was made, the edges of the perforation cut away, and the wound in the stomach drawn together, end to end, and separated in the middle, as in pyloroplasty. Both patients are in good health.

Mr. F. T. PAUL agreed that Frank's modification of Hahn's operation of "gastrostomy" was the best, but unless a diverticulum of from 2 ins. to 2½ ins. in length could be withdrawn to form the fistulous passage in the abdominal wall; it was better to do Senn's operation, which he thought the more efficient, but not so easily recovered from as Frank's. He has ceased to use all mechanical appliances, except Murphy's button, and this he believes might generally be dispensed with.

In "gastro-enterostomy" he considered there was a danger of the intestinal juices escaping into the stomach, and of the anastomosis proving only temporary; the former trouble was more common in the posterior operation, and rarely met with when the opening was made in front. This operation cannot compare with either pylorotomy or pyloroplasty in the benefit afforded to the patient.

Pylorotomy was never likely to be a frequent method of operation in cancer of the pylorus, owing to the fact that by the time the diagnosis is made, the extent of the growth, fixation, &c., renders it unfeasible.

Pyloroplasty had given him the best results in practice. With reference to the suture of perforated gastric ulcer, he considered that drying out the peritoneal cavity was better than flushing, he always washed viscera that were withdrawn from the abdomen, but limited the internal flushing to localised septic tracts that were isolated by adhesions or otherwise.

Mr. ROBT. JONES referred to a patient with large nodular mass at the pylorus, so fixed that, after opening the abdomen, pylorotomy was considered undesirable. Now, three years later, the patient is nearly well, and the tumour has disappeared. This was of interest in view of reported cases of gastro-enterostomy for malignant disease, when years had passed and the patient lived. A microscopic examination was necessary before malignancy could be pronounced.

Mr. W. THRELWALL THOMAS drew attention to the un-

satisfactory state of our knowledge of the pathology of the stomach, two of the cases referred to in the paper being due to syphilis, a cause rarely mentioned. Familiarity with the details of visceral suture, obviated the use of mechanical appliances, such as tubes, palates, and buttons. It was necessary to deal boldly with the stomach in such cases as perforated gastric ulcer, cutting away the margins of the ulcer until normal stomach wall was reached, and continuous suture with silk was a great advantage. He advocated early operation in cases of gastric ulcer with perforation, and "mopping" in preference to washing out the abdomen. The early recognition of the time when medical means prove unavailing is necessary for an early resort to surgical means if considered advisable after consultation.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

MEETING HELD IN THE MEDICAL INSTITUTION, LIVERPOOL, FEBRUARY 15TH, 1900.

The President, Dr. HELLIER, in the Chair.

Dr. BRIGGS, Liverpool, showed (1) a fibro-myoma, almost completely calcified, removed from a patient, *æt.* 60, by Baer's operation. The tumour weighed 5½ lbs. The patient made a good recovery. (2) Calcified fibro-myoma weighing 5½ lbs. enucleated from the parametric cellular tissue of a woman, *æt.* 52. The patient died on the eighth day from exhaustion. In both cases ascites was present.

Dr. LLOYD ROBERTS.—Calcified fibro-myoma, the size of a child's head, removed post-mortem from a woman, *æt.* 70.

Dr. T. GRIMSDALE, Liverpool.—Uterus with multiple fibro-myomata removed per vaginam by morcellation.

Dr. T. E. GEMMELL, Liverpool.—Fibro-myoma removed by enucleation from a uterus three months pregnant. The pregnancy was not interrupted.

Dr. BURTON, Liverpool.—Pedunculated fibro-myoma removed by abdominal section.

Dr. DONALD, Manchester, read notes of a case of RUPTURED EXTRA-UTERINE PREGNANCY, AND SHOWED THE SPECIMEN.

The patient, *æt.* 30, had been married 4½ years, and had no previous pregnancy. The menstrual periods were regular until October, 1899, but in that month the period was delayed four days. Uterine hæmorrhage then came on and lasted until the date of operation (16 weeks.) In December she had sickness and nausea and was seized with a pain in the right iliac region. Early in January the sickness was very severe. The abdomen was distended and tender, and an obscure swelling was felt bi-manually in the right iliac region. The diagnosis was tubal pregnancy with rupture into the right broad ligament. Palliative treatment was recommended as it seemed probable that the embryo had succumbed. The conditions improved somewhat—although the sickness was at times troublesome—until February 3rd, when she had severe abdominal pain and marked increase of sickness and exhaustion. On February 6th abdominal section was performed. The abdomen contained large blood clots and much fluid blood. A four months' fœtus and placenta were found lying loosely amidst coils of intestine. No sac and no amniotic fluid were seen. The pelvic organs were not felt, as they were completely shut off by adhesions. The abdomen was cleansed with gauze sponges, but no attempt was made to remove clots adherent to intestines. A large quantity of iodoform gauze was packed into the abdomen. Convalescence, after the first forty-eight hours, was uninterrupted. *Remarks.*—The case was probably one of secondary rupture into the abdomen. Neither the fœtus nor the placenta showed any signs of maceration or degeneration. From a clinical point of view it is interesting that the most prominent symptom throughout was the vomiting, and that even after the final rupture, pain and exhaustion and symptoms of peritonitis were more marked than the signs of hæmorrhage.

Dr. J. B. GRIMSDALE (Liverpool) related a case o

"Metrorrhagia" occurring in a single woman, æt. 31. The bleeding had been almost continuous for three years. She had been in bed for eighteen months, and various modes of treatment, including plugging and electrical treatment, had been tried without effect. Vaginal examination revealed no cause for the bleeding, the uterus being small and mobile. The uterus was explored and curetted, but three weeks later the bleeding again commenced with little diminution of the amount. The patient was extremely anæmic. Examination of the blood gave evidence of simple anæmia only. Abdominal section was performed, and the ovarian arteries were ligatured. The bleeding immediately ceased, and since then the patient has had a normal menstrual period lasting five days. Remarks were made by Dr. Briggs, Donald, and Professor Sinclair. Dr. Grimsdale replied.

Dr. MATHAN RAW, Liverpool, related two cases of "eclampsia" treated with success. In the second case the patient appeared to be moribund for some hours after delivery. Two pints of normal saline solution were transfused into a vein. This was followed by immediate improvement and life appeared to be undoubtedly saved by this measure.

Dr. RAW also showed a full-term fœtus removed by Cæsarean section after repeated attempts had been made to deliver by forceps. The child was dead but the scalp and vertex showed extensive subcutaneous hæmorrhage.

BRITISH ORTHOPÆDIC SOCIETY.

MEETING HELD SATURDAY, FEBRUARY 17TH, 1900.

MR. G. CHISHOLM WILLIAMS showed cases of (1) Ganglion of the Extensor Tendons of the Foot; of (2) Caries of Dorsal Vertebra; and (3) Severe Hallux Valgus with Hammer Toes.

Mr. JACKSON CLARKE, commenting on the first case, said that he thought partial excision of the sac the best treatment.

Mr. WILLIAM THOMAS said that he had never seen recurrence after subcutaneous free division of the sac and extrusion squeezing out of the contents.

Mr. ROBERT JONES said that simple ganglion got well after rupture, but pressure must be kept up for some time afterwards. In other cases he found that injection of a few drops of liquefied carbolic acid effected a cure.

Mr. NOBLE SMITH said that he preferred subcutaneous puncture and evacuation of the contents, followed by pressure. In the event of recurrence he used Tod's glycerine injection.

Mr. MUIRHEAD LITTLE said that he thought that the case shown was one of ganglion of the sheath of the tibialis anticus.

Mr. WILLIAMS, in reply, said that he had never found any difficulty in curing ganglia by rupture, provided that enough pressure was applied. In the case of hallux valgus he could trace no history of rheumatism. The patient has flat foot.

TUBERCULOSIS (?) OF SHOULDER.

Mr. MUIRHEAD LITTLE showed a boy of ten with a stiff shoulder, probably due to tuberculosis. There was a history of injury. When first seen nine months ago, the humerus was firmly fixed on the scapula, its head was slightly displaced upwards and inwards. There was no swelling and no sign of local inflammation. Under an anæsthetic the humerus could be easily moved on the scapula through 90 degs. of abduction. Rotation was very limited. There was a roughness in the movement of the joint. The other shoulder-joint allowed an unusual degree of mobility, so that the boy was able to turn his olecranon to the front. Both elbow-joints were normal except for slight hyper-extension.

Mr. ROBERT JONES thought the case was one of tuberculous disease with subluxation, and disadvised passive movement. The best plan was to keep the parts at rest until inflammation had subsided, and then to try to impart as much mobility to the scapula as possible. Happily the scapula was very accommodating, and such treatment gave better results than excision.

Mr. NOBLE SMITH recommended drilling into the head of the humerus. This often promoted absorption.

Mr. JACKSON CLARKE showed a skiagram of a somewhat similar case. In this ankylosis dated from nine months of age, and there were signs of local inflammation. He believed it was tuberculous, and not syphilitic.

Mr. WILLIAM THOMAS thought there was much subluxation in Mr. Little's case. He believed that excision would give the best result.

Mr. JOHN POLAND agreed that the case was tuberculous. Such cases were so rare that every example was interesting. His experience was that tuberculous of the shoulder differed considerably from that in other joints. Its progress was very insidious, the amount of deposit being at first small, and very slight injury would produce dislocation. He thought that nothing short of excision would produce a movable limb.

CASE OF HALLUX VARUS.

Mr. POLAND showed a skiagram of a case of hallux varus probably of paralytic origin. He had replaced the part after dividing the tendon of the abductor pollicis and the internal lateral ligament. He also showed casts of the hands of an infant with defect of the thumb on one hand and redundancy of digits on the other.

Mr. JACKSON CLARKE showed a skiagram of an old case of dislocation of the hip following coxitis, on which he had performed intertrochanteric osteotomy to correct adduction. The pelvis showed secondary changes on the affected side.

Mr. POLAND also showed a skiagram of a case of separation of the lower epiphysis of the radius. He pointed out that a radiograph would not show the separation unless there were displacement.

HALLUX VALGUS AND HALLUX VARUS.

Mr. JACKSON CLARKE, in opening the discussion upon hallux valgus and hallux varus, observed in regard to the former that in rheumatoid cases the head of the metatarsal bone presented a groove denuded of cartilage and corresponding to the inner edge of the base of the first phalanx. *Congenital cases of hallux valgus* were referred to. He considered that they were due to intra-uterine pressure. A variety of causes had been suggested as most commonly producing *acquired hallux valgus*; but he thought the more severe cases were due to the combined action of a predisposing and an exciting cause. The former was usually rheumatoid arthritis and the latter wrongly-shaped boots. The more commonly occurring *concomitant deformities* were hammer-toe, flat-foot of the ordinary and of the transverse type (the latter being sometimes complicated by metatarsalgia). The *treatment* consisted of active and passive exercises, instrumental and operative measures. When operation was called for excision of the whole of the head of the first metatarsal bone was to be preferred. *Hallux varus* was seen as part of congenital equino-varus, and as an acquired condition in severe genu valgum, some cases of paralysis, &c. Pronounced hallux varus was present in some cases of dichotomy of the great toe, and it might be caused by paralysis in some cases. *Results*.—Mr. Clarke expressed his belief that every case of hallux valgus was curable, the most troublesome cases being those in which a second hammer-toe had been (quite unnecessarily) removed previously to the patient being seen.

Mr. JOHN POLAND showed a skiagram of a remarkable congenital case, the second phalanx being completely displaced to the inner side of the first. He pointed out, as regards hallux valgus, that there was a class of cases of great interest in children from 14 to 15 years old who had not worn tight or narrow-toed boots.

Mr. ROBERT JONES preferred to treat the subject from a clinical rather than a pathological standpoint. He was in the habit of dividing or excising an inch of the tendon of the great toe. The best treatment in pronounced cases was excision of the head of the first metatarsal bone, failing which gradual mechanical correction might be resorted to. He had seen a boy, æt. 14, with well marked hallux valgus, yet this boy

had never worn boots or shoes. Osteotomy of the shaft of the first metatarsal bone was useless.

Mr. TUBBY agreed as to the osteo-arthritis nature of the deformity, but he would say that not merely 50 but 90 per cent. of the cases were due to rheumatoid arthritis, which he believed was a dyscrasia, which was apt to fall upon any joint which happened to be exposed to pressure or irritation. If enough bone was removed there was no need to divide the extensor proprius Pollicis.

Mr. MUIRHEAD LITTLE said the displacement of the sesamoid bones in hallux valgus showed plainly in skiagraphs in the first interosseous space, and had been removed by at least one surgeon as the probable cause of symptoms! Toe posts were useless.

Mr. KEETLEY thought that excision of the head of the metatarsal bones was the best. Wedge osteotomy was sometimes effective. He had never succeeded in curing a case by any mechanical appliance, though he had given many cases a very fair trial. He thought that there were two classes of cases: those associated with flat foot, and the great majority those caused by improper boots. He did not believe, apart from rickets, that hallux valgus affected people who had never worn boots.

Dr. BLAGE said that there were in his opinion three classes of cases. 1. Congenital. 2. Due to rheumatoid arthritis. 3. Due to tight boots. When he was a student he had seen operations of osteotomy, and the immediate results seemed excellent, but when he got into practice he found that the trouble recurred after osteotomy, and excision of the head of the bone had to be performed.

Mr. NOBLE SMITH said that in the slighter cases much might be done by persuading the patients to wear proper boots.

France.

[FROM OUR OWN CORRESPONDENT.]

PARIS, March 4th, 1900.

ERECTILE TUMOURS.

M. LE DENTU read a paper at the meeting of the Académie de Médecine on the treatment of angiomas by the injection of coagulating liquids. The solution employed was that of Piazza, and the quantity injected varied from two to ten drops for the small tumours and from twenty to forty drops for the largest angioma at one sitting. The instrument used was the ordinary Pravaz syringe, and the liquid was introduced very slowly. Before operating, a ring of some material was placed around the tumour in order to prevent the blood from returning into the circulation, and also the escape of clots beyond the erectile zone. The ring was maintained *in situ* twenty minutes, so as to avoid the danger occurring from a possible embolus, for the coagulation in the vessels and the erectile caverns was far from being instantaneous. The decrease of the tumour frequently required several months to be complete. In the majority of cases one injection was sufficient to arrest the development of the tissue. At a distant date—three months, six months, or even a year—if the angioma had not disappeared, the injection might be renewed. The results obtained by this method of treatment were, the speaker said, encouraging. If electrolysis should be preferred for angioma of the face, it was none the less true that ignipuncture and coagulating injections offered important resources to country practitioners who did not possess an electric apparatus. M. Berger opined that extirpation was the best treatment of erectile tumours where they were not too extensive; where extirpation was not feasible preference should be given to ignipuncture or to the galvanic

cautery. Another member said that he obtained very good results with the thermo-cautery.

INFLUENZA.

Prof. Huchard read a paper in which he insisted on the benefit derived from administering to persons attacked with the grippe, and at the very outset, one large dose of hydrobromide of quinine, 20 to 25 grains, the doses of 10 grains habitually employed were entirely insufficient. A small quantity of ergot of rye (5 to 6 grs.), might be associated with the quinine. If the nervous depression were considerable, a fiftieth of a grain of strychnine might be ordered. In the majority of cases it would be well to facilitate the urinary secretion so frequently compromised, by prescribing milk régime.

Dr. Hayem considered that the massive doses recommended by the above speaker would provoke gastric disturbance, which would be far from improving the condition of the patient. He was not a partisan either of the milk diet, the customary food should be allowed.

Germany.

BERLIN, March 3rd, 1900.

ACROMEGALY AND MYXEDEMA.

In *Volkmann's Klin. Vwag.* is an article by F. Pineles on the relation of acromegaly to myxedema and other blood-gland diseases. To acromegaly, which is almost always found associated with a pathological change of a blood-gland (hypophysis) are often associated other morbid alterations of other blood glands i.e., glands with internal secretions. Above all, the genital glands almost always exhibit some disturbances of function which express themselves either in a primary genital atrophy or clinically in permanent amenorrhœa. Further, there are in most cases various changes in the thyroid, and clinically a combination of acromegaly and myxedema or Basedow's disease. In the same way the oft-recurring glycosuria and diabetes point to anatomical or functional disturbance of the pancreas. Also in myxedema and Basedow's disease a number of symptoms are observed which are connected with morbid changes of other blood glands than the thyroid. Typical pneumonia of Basedow have often preceded a myxedema. Both in acromegaly and myxedema complete abeyance of the sexual function is a frequent occurrence. There is a connection between Basedow's disease and amenorrhœa. It has been experimentally proved that atrophy of the genital organs follows extirpation of the thyroid in animals. From this it follows that acromegaly, myxedema, cretinism, Basedow's disease, and in many instances diabetes, also are diseases of blood glands, in the course of which anatomical or functional disturbances of other blood glands arise. There seems to be, therefore, an anatomical and physiological relationship between many blood glands which shows itself clinically in the fact that in disease of one blood gland symptoms crop up that point to disturbance of function of another blood gland. As regards the pathogenesis of acromegaly, the hypophytic disease is not to be classed as a symptom, but as a cause of the disease.

In the *Deutsch. Zeit. f. Chir.*, 53, 304, Dr. Carl Frantcha contributes a report on three cases of

ACUTE DISEASE OF THE PANCREAS.

In two of the cases, after a considerable period in which gastric pain had been present, symptoms of ileus suddenly came on. Laparotomy was performed. In the one case there was necrosis of fatty tissues; in the other nothing beyond a slight redness of the serous covering of the intestine. Death took place in both cases; and in both necrosis of the parenchyma of the pancreas with interstitial hæmorrhage was found.

In the other cases a cystic tumour had formed only a few weeks before below the left ribs, which might be a hydro or a pyonephrosis. The kidney was cut down upon and found to be healthy. The tumour lay in the *bursa omentalis*; the walls were torn in the attempt to remove it. It was therefore stitched to the wound. Death followed from peritonitis. At the autopsy the pancreas was found to be converted into a cheesy, opaque, white mass, and microscopically the tissues were found to be necrosed. The cyst wall was pure connective tissue. The author classifies the case a pseudo cyst, i.e., such as arise in inflammation of the pancreas. There were no pancreatic ferments in the slightly turbid fluid contained in it.

At the meeting of the Medical Society of the 14th ult. Hr. Virchow showed bony preparations from a case of

CYSTOCARCINOMA TOGETHER WITH CHALKY METASTASES IN THE INTERNAL ORGANS,

the lungs, stomach, and kidneys. During life there had been a hypnotic condition of the vertebral column. In the first sacral vertebra was a large cavity. The whole condition pointed at first to cystoid formations, until further examination into the not smooth but rough walled cavities showed a milky fluid such as is met with in medullary tumours, and which was plainly in some relationship to a flat carcinoma discovered in the stomach, and which looked very much like an ulcer. The rarely observed combination with chalky metastases in the case had been determined by Davidsohn, who had for a long time been working on the subject of such metastases.

At the Free Society of Surgeons Hr. Heinze showed a specimen of

SPONTANEOUS RUPTURE OF THE ŒSOPHAGUS.

The patient was admitted into the St. Hedwig Hospital in a very bad condition exhibiting the symptoms of perforating ulcer of the stomach. At the autopsy the stomach was found to be healthy, except for some catarrhal gastritis, but in the œsophagus 6 cm. above the cardiac orifice was a tear 3 cm. in length. There was nothing about the preparations that pointed to carcinoma, stenosis, or diverticulum, and microscopic examination only revealed a round-celled infiltration at the margin of the rent, simple signs of recent inflammation. There was no emphysema of the skin, as was generally met with in such cases.

Hr. Heintz then related a case of

RUPTURE OF THE URETHRA WITH PRIMARY SUTURE.

A man, whilst unloading boards, fell astride on the edge of one. He fainted for a few minutes, and when he came to himself complained of acute pain in the perineum. He was taken to the hospital, and there was extensive extravasation of blood in the perineum, the scrotum was discoloured, and the discolouration extended to the inguinal region. No urine could be passed.

The urethra was laid open and found to be completely torn across. The peripheral end was easily found, the proximal only after some searching. The two ends lay about 5 cm. apart. The rent was at the junction of the bulbous and cavernous parts. The speaker succeeded in bringing the margin together by interrupted sutures over which the bulbo-cavernous muscle was sutured. The wound was then packed. At first a few drops of urine came through the wound, but in a few weeks healing took place without a fistula remaining. Some weeks later the patient reappeared with symptoms of commencing stricture, but at the time of reporting a No. 20 Charrière bougie could be passed without any difficulty. The suturing in stages had been a manifest success; it had shortened the process of healing, and had allowed a large lumen for the urethra.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, March 3rd, 1900.

CONGENITAL HYPERTROPHY OF PYLORUS.

At the "Gesellschaft der Aerzte," Huny presented a boy, æt. 11, to the Society who had suffered from infancy from general alimentary disorder, whose principal symptoms were, swelling of the abdomen, especially in the left lower region, vomiting large quantities of half-digested food, false appetite, constipation, &c.

The objective symptoms noticeable were splashing or gurgling in the swollen region, cyanosis and undoubted emaciation. By blowing up the stomach with carbonic acid gas to determine its limits it was found to be enormously enlarged, extending downwards to the symphysis pubis.

In December, 1899, laparotomy was resolved on to discover the real cause, when a concentric thickened ring of hypertrophy around the pylorus, was found about a finger's breadth in width, without any cicatrix or other adhesions that would raise any suspicion of preceding inflammation. The wall of the stomach itself was greatly hypertrophied, being about a finger's breadth thick. Gastro-enterostomy was performed with a Murphy's button, after which the whole symptoms disappeared. The liver before the operation could not be percussed, but on operating was found lying across the median line and enlarged, but resumed its normal size and position after operation. The Murphy button is still *in situ*, as shown by the Röntgen rays, probably due to the enormously thickened wall of the stomach.

This he thought was doubtless a muscular congenital hypertrophy of the pylorus, which he thought was consistent with Tandler's case last week, which was a duodenal atresia of a congenital origin.

Of the literature on this subject, only four are on record; three of these were in the first year of life, and one boy in the sixth year. Two of the operations ended fatally.

SEROUS IRIDO-CYCLITIS.

Paltauf next showed photographs of a patient, æt. 22, who consulted him in 1898 for serous irido-cyclitis without any appreciable cause.

In the following year a number of small tumours appeared as unaccountably under the skin, which were quite movable along the neck, sterno-cleido-mastoideus

and back; along both forearms to the shoulders, and on the calves of the legs. The individual gland groups, such as the axilla, occipital and inguinal, were not markedly enlarged to assist in the diagnosis. Concurrent with these small tumours under the skin a dull precipitate occurred on the posterior surface of the cornea. The microscopic examination of one of these small tumours which was excised showed that it was situated in the upper part of the sheath of the muscle and could be passively moved from one place to another. It was composed of granulation tissue with epithelial cells among which coursed fine vessels and leucocytes. From these data one could instantly conclude that the tumour was not a neoplasm, and must therefore be an inflammatory product—tuberculosis, actinomycosis, or some other morbid condition. Against tuberculosis the vascularisation of the mass was decided, as tubercle tends to assume a retrograde metamorphosis, while no infectious agent could be found to confirm actinomycosis, either by microscope, cultures, or animal injections, though several of the latter were performed, but all healed perfectly without any trace of infiltration or general disturbance. Internal changes were dulness in lower part of right lung, cough, but nothing to be found in sputa, while the spleen was greatly enlarged.

Other more unusual diseases such as multiple enlargements, cysticercus, and foreign bodies which the microscope could not discover. *Saccharomycetes* has usually a discharge which the present case did not exhibit. The diagnosis may, therefore, be said to be shrouded in darkness.

Bergmeister said that he had seen the patient with the morbid process in the iris. In the case of miliary tuberculosis the size of the tubercles was small in the iris between which small vessels were usually found, giving the tubercle a greyish color and sometimes a scarlet red. In many cases where the vessels become absorbed and the tubercle disappears, iridectomy may be required for *seclusio pupillæ*. Vision is usually impaired in both eyes.

Konigstein said he saw the patient a year ago, when he suffered from irido-cyclitis serosa, but was unable to give the etiology of the disease.

Paltauf said the blood had been examined and found normal. The presence of any parasite was excluded by the discovery of granulation tissue.

Fuchs said he had a female patient a short time ago with a similar histological tumour on the eyelid, which he removed without any subsequent infiltration or bad result. There was no appearance of other tumours on the body. Paltauf said that a similar case was recorded by Riehl, where the tumour occurred in the cartilage of the ear, which was under observation for thirty years. It was originally caused by a foreign body.

The Operating Theatres.

GREAT NORTHERN CENTRAL HOSPITAL.

TWO CASES OF LAPAROTOMY.—MR. PEYTON BEALE operated on a boy, æt. 10, who had been admitted a few hours previously suffering from an indurated mass in the right iliac region, acute pain in the left iliac region, constipation of fifty days' duration, vomiting, temp. 103, and furred tongue. The history of the case was as follows:—

The boy had been suddenly seized with severe pain in the left side of the abdomen, which came on immediately after dinner one week previously; he vomited and had a rigor. He was kept quiet, and purgatives were administered. His bowels acted well next day, but a hard swelling appeared in the region of the cæcum, the bowels could not then be made to act, although enemata were given frequently. Upon admission there was found to be a soft spot in the centre of the indurated mass, and the case was diagnosed as one of acute suppurative appendicitis. The patient being anæsthetised and the skin of the abdomen prepared, an incision of about 3 inches was made, its centre being the soft spot above indicated. A large irregular cavity was opened, and about four ounces of very foul pus were evacuated. In this cavity there was found—lying quite loose—the tip of the vermiform appendix. The cavity was washed out with 1:60 carbolic lotion, and a gauze plug inserted, the skin wound was reduced to about 1½ ins. in length by the introduction of two stitches, and the wound was dressed as usual.

The same surgeon operated upon a woman, æt. 34, who had been admitted with the following history—three days previously she had a severe attack of griping pain in the abdomen after over-reaching while attempting to get something off a high shelf. She had some nausea, and, feeling very ill, went to bed. The pain got worse, and vomiting commenced, and became fecal in three days. She had also absolute constipation in spite of frequent enemata. Upon admission she looked very ill, was vomiting freely, the vomited matter being brown and fecal, the abdomen was much distended, and it was impossible to feel anything through its walls. The patient stated that about two years previously she had been an in-patient at another hospital and suffered from "peritonitis." The case was thought to be one of obstruction by a band. Laparotomy was immediately performed, and although the whole of the small and large intestines were carefully examined, nothing abnormal could be found except two thin adhesions about 2 inches in length, passing between the parietal peritoneum of the anterior abdominal wall and the mesentery. There was no indication of any part of the intestine having been "nipped" by either of these bands or by anything else. The small intestine was punctured by a trocar and cannula, and the gas allowed to escape freely outside the wound. A fine silk suture was then inserted so as to close the aperture made by the trocar, the abdomen was filled with hot saline solution, and the wound closed and dressed in the usual manner.

Remarks.—MR. BEALE said, as regards the first case, the surgeon was lucky if he could get at these cases before general septic absorption had occurred, but whenever such a case presented itself, the soft spot—or it might be a small oedematous area as large as a sixpence only—should be sought for, preferably under an anæsthetic. He stated that in every case in which he had found this small soft or oedematous area, he had at once made an incision into it, and had always found the appendix, the tip generally, immediately beneath, and generally more or less gangrenous.

He said that the most important point to be remembered in appendix cases of this class was, "do as little as possible." Let out the pus and explore the cavity gently with the finger, but on no account enlarge the incision or scrape violently at the walls of the cavity.

By so doing, one ran the greatest risk of infecting the general peritoneal cavity; it was, moreover, of no use to try and ligature the stump of the appendix, for it would be found nearly always to be in a rotten state. He said also that in the majority of these cases the pain was anywhere but over the disease.

As regards the second case, he said the symptoms were remarkably severe, and he believed they were caused simply by an unusual strain put upon one or both of the small bands which were found. He had operated upon several cases of the same kind previously where in some instances nothing was found as a cause for the severe symptoms, but all had recovered completely, and the operation had removed all the symptoms at once. He stated that simple stretching of peritoneum might cause all the symptoms of complete obstruction, and especially in the case of the visceral peritoneum. He mentioned a somewhat similar case on which he had recently operated in King's College Hospital. Here the patient, a boy, was too ill upon admission to give any history at all, but he presented two abdominal sores where laparotomy had been previously performed. It was assumed that these had been done for tuberculous peritonitis, as he has had also some tuberculous glands in the neck, but on this occasion nothing abnormal was found with the exception of numerous adhesions between the mesentery and the under surface of the old scars. One peculiar feature of the case was the presence of gas, free in the peritoneal cavity. This boy made an uninterrupted recovery, and the operation relieved all his symptoms.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, MARCH 7, 1900.

THE GENERAL MEDICAL COUNCIL IN ACTION.

FROM time to time the august body which rules the destinies of the medical profession shakes off the bonds of its lethargic disposition so far as to prosecute some offender against the Medical Acts. Such

an event took place last week, when a decision of the first importance to the medical practitioners of the United Kingdom was delivered in a London Police Court. As almost invariably happens, the Council prosecution was that of a man whose name had formerly been on the Medical Register. At one time the defendant, E. W. Alabone, was a member of the Royal College of Surgeons of England, but in 1886 the College removed his name from its list for disgraceful conduct. The specific offence for which erasure took place was the appearance in *Moonshine* of an article laudatory of a special cure for consumption. Since the time of his removal from the Register he had, in accordance with the time-honoured observances of his fraternity, continued to practise medicine in a free and open manner. The only difference was that he described himself as "Edwin Alabone, M.D. Bellevue College, M.D. Phil., U.S.A.; D.S.C., F.R.M.S., ex-M.R.C.S. Eng." For using those descriptions he was now prosecuted by the Council, on the ground that the Act was intended to enable the public to distinguish between qualified and unqualified men, and that defendant was likely to deceive the public into the belief that he was registered under the Medical Act. The weakness of such a count must be at once evident to the veriest tyro in such matters, and to set the ponderous machinery of the law in motion upon an issue of that kind was a work of sheer and simple supererogation. With little hesitation the magistrate, Mr. Paul Taylor, placed the Council out of court. Defendant, he said, gave clearly the origin of his degrees, and expressly stated that he was an ex-member of the College of Surgeons. That being so, he found that Alabone described himself accurately as that which he was, without any intention whatever of misleading the public. The summons was accordingly dismissed, with ten guineas costs against the Council, and as the decision was based upon matters of fact and not of law, the magistrate refused to state a case for the superior Court. The actual cost of this ill-advised prosecution, needless to say, far exceeds the sum in which the Council was mulcted, and the loss is ultimately recouped from money paid by registered members of the medical profession. The money will not have been ill spent, however, if it call attention to the anomalies of medical legislation, and to the feebleness of the General Medical Council. What body with any common-sense business views would have undertaken a costly prosecution of a man for the publication of statements that are obviously and admittedly true? What must we think of the legal advisers of the General Medical Council for permitting so futile a step to have been taken, unless, indeed, the matter lends itself to the subtle vagaries of intellectual treatment which lead to lawsuits as certainly as a fierce conflagration ends in ashes? Why should the counsel for the prosecution have pointed out that defendant by using the titles complained of was likely to make the public believe he was registered under the Medical Acts? There are many legally qualified men in this country who are not registered. Will the Council prosecute

any of them for deceiving the public in a similar way into the belief that they are registered? Perhaps the Council and its legal advisers would kindly point out how the case of Alabone differs from that of the non-registered holder of a British qualification practising somewhere within the confines of the United Kingdom. Both publish and assume titles that are registrable in this country, but are not so registered. The fact of the matter is that registration should be compulsory upon all legally qualified practitioners of medicine. After the ridiculous fiasco of the Alabone prosecution even the General Medical Council may begin to perceive that the present voluntary system has its defects. Any other governing body would long ago have agitated for increased powers from the legislature to restrain from practice men whose names have been erased from the Medical Register. Not so the Council, which has simply ignored the open flouts and defiance of men who have proclaimed to the world by the medium of brazen plates that they have fallen from their former estate of legal qualification. It is often asserted that the Council has the ear of Government, and there can be no doubt whatever that its influence in that direction is great. Why, then, have we had none of the reforms that are so urgently needed in the medical world? Even now there is time for the Council to conciliate the main mass of the profession by increasing the number of direct representatives, and by taking vigorous steps to make registration compulsory, to prevent disrobed practitioners from further practice, and to obtain stringent laws against unqualified practitioners. The present constitution of the Council, however, hardly encourages any hope of progress in the foregoing directions. They are drawn mainly from the members of the consultant and teaching classes, to whom unfair professional competition means nothing, and the preservation of class privilege everything. The only way of solving that difficulty appears to consist in choosing the representatives of qualifying bodies on a broad electoral basis instead of allowing them to be nominated by autocratic and irresponsible intramural councils. Before finally leaving the case of the Alabone prosecution it may be well to ask how an unqualified man has managed about his death certificates for so many years. The recent action of the Registrar-General on this point opens up a prospect of an indirect attack upon a disrobed practitioner. We commend this point to the Medical Defence Union, a body which tempers legal subtlety with sound common-sense, and we venture to suggest that possibly with the aid of the local registrar, and a little timely pressure from Somerset House, the Union may sometimes succeed in bringing offenders to book, or, at any rate, in considerably restricting their field of action.

THE WAR AS A CAUSE OF INSANITY.

DR. CLOUSTON has just read his annual report to the managers of the Edinburgh Royal Asylum and

the public who are interested in such matters, and has taken occasion as usual to make some very striking remarks—one might almost call them sensational. If any man has made the subject of lunacy, its manifestations and its causes, attractive and interesting to the general public it is Dr. Clouston. Perhaps in writing for the general public as he undoubtedly does to a large extent, there is danger of departing from the scientific in order to satisfy the popular appetite and popular digestion, with what may be regarded as popular science. Thus, while touching on several points of interest, Dr. Clouston is not forgetful of the times, the sensations of the moment, and the great crisis through which we are passing, and he strikes a note which arrests attention when he speaks of the war and its influence in the production of insanity. In this connection he makes some very remarkable statements. 1. The statement that influenza is more productive of insanity than the war. If he said that influenza was productive of insanity without any comparison of other causes we should agree with him, but when he says that the war has produced no insanity, and therefore that influenza has more effect in the production of mental disease, we think that he is just travelling too fast. Putting influenza aside altogether, we should ask what is the value in Dr. Clouston's mind of the so-called moral causes of insanity, and if he admits that those so-called moral causes are a feature which has to be reckoned with, can he deny that the war, with all its attending anxieties, its suspense and despair, its multitude of bereavements, and consequent poverty and sickness, contributes to the moral equation and the immense mental result that must be recognised by and by? We have said that Dr. Clouston is travelling too fast, and what we mean is this, that the war is not yet over. We cannot even count the material and financial cost of it. It has not been of long duration, but will Dr. Clouston dispute the fact, that long after the war is over, its effects on moral and social character will still be felt, and will still produce a depressing effect on many nervous systems. If we consider for a moment the anxiety, strain, uplifting and down setting of our emotions, the distraction from business, the inhibition of that energy which should be expended in the ordinary channels of daily life, and this in people who have no relatives at the seat of war. How much should this be multiplied if applied to relatives of soldiers "at the front?" We take it then that Dr. Clouston has not regarded this subject with that far-seeing scientific acuteness and wisdom which we should have expected of him. 2. Perhaps, less hasty is his generalisation from the fact of the war having not yet produced much, if any, insanity, that this is evidence of the selfish and unaltruistic character of the present day. Here, Dr. Clouston is speaking from observations which are the result of evidence culled from his large experience of human nature, and we are not prepared to dispute this, but there is no more selfish character than love of offspring, and this will

show itself intensified through suffering during the present war, and a morbid factor which will yet tell its own tale. Although we have sometimes to disagree with Dr. Clouston, we have also to acknowledge how quick he is to seize on the circumstances of the moment, and the events of public interest, and to throw light on them from a psychological point of view. We have no doubt that when his report appears it will be read with interest, all the more because of the controversial questions which it has raised.

THE PATHOLOGY AND TREATMENT OF APPENDICITIS.

ALTHOUGH the subject of the pathology and treatment of appendicitis has been under discussion for many years past we are still far from a complete knowledge of this curious lesion. It is now recognised on all hands that appendicitis is always of infective origin, and this observation applies as well to a mild form, such as mere appendicular colic, as to the graver forms associated with perforation, gangrene, and peritonitis. This is a very important point, because it establishes once and for all the pathological identity of all forms of the disease, and it explains why it is impossible to forecast in a given case the ultimate result. As was clearly pointed out in the course of the discussion on the subject which took place last week at the Medical Society of London, the so-called catarrhal appendicitis of to-day may be the fulminating appendicitis of to-morrow, in fact, as physicians know but too well, the difficulty of distinguishing *ab initio* between mild and serious cases is more or less insurmountable. Physicians and surgeons still differ greatly in opinion as to the necessity for operation, and as to the precise moment at which such operation is best undertaken, but order is gradually being evolved out of chaos, and this difference of opinion now only obtains in regard to first attacks. There is a general consensus of opinion as to the desirability of operating in the chronic recurrent cases, and in the cases with severe initial onset. Although no hard and fast rule can be laid down for the guidance of physicians in determining the necessity for surgical intervention it is beginning to be recognised that grave responsibility is incurred by the practitioner, called to a case in the early stage, that is to say, at a stage when it is impossible to draw a sound conclusion as to its probable course, who refuses to advise operation. Great stress was laid on rapidity of the pulse as an indication for surgical intervention and this symptom is unquestionably far more significant than the temperature. Another interesting point is that the absence of swelling or tumour over the region of the appendix is not *per se* a contra-indication for operation; indeed, such cases not unfrequently prove to be of the graver kind. The presence or absence of this sign depends upon the anatomical position of the appendix, and this, as is well known, varies very greatly. A sudden onset, with a rapid pulse and tenderness over the appendix, with or without the formation of a tumour, suggests the

desirability of operation. A more gradual onset, with a steady pulse and early formation of a tumour, justifies delay, though this must be qualified by the absolute necessity of watching the patient closely taking the pulse rate every hour or two, the better to appreciate any sudden change in the condition. Surgeons in general are agreed in discountenancing the administration of opium and no doubt its routine employment in large doses serves only to mask the symptoms and to induce a sense of security not justified by the condition of the patient. Nevertheless, this drug is capable of rendering great service if administered with one or two provisos. First of all no opium should be given until the practitioner has made up his mind as to the sort of case he is dealing with, especially in view of the necessity for operation. Even then it should not be given continuously or in doses which would determine a condition of narcosis. Subject to these conditions opium calms the restless irritability of the patient, and while contributing to the relief of his suffering it does not hinder diagnosis nor prejudice an operation should this subsequently be decided upon. The fact that a very large proportion of the cases which are described as ending in recovery, relapse after a variable interval and are ultimately operated upon, renders it incumbent upon us to accept the term "recovery" with some reserve. One precaution imposes itself, viz., that a patient whose symptoms, after a first or second attack, have subsided, ought to be kept under observation in order to determine by periodical inspection whether the lesion has completely cleared up. In many cases it will be found that some induration or tenderness over the region of the appendix persists even after apparent recovery, and such a patient must be regarded as the possessor of an explosive focus which may at any moment place his life in jeopardy. The statistics of the so-called recoveries are still incomplete, but if it can be shown that sooner or later the majority recur a strong case will have been made out for operative treatment as a routine measure in dealing with this affection.

Notes on Current Topics.

The Dublin Sanitary Inquiry.

THE Commission appointed by the Lord Lieutenant has been sitting for the past three weeks from day to day, but, in our opinion, the result, so far, is not altogether satisfactory. A number of Medical Officers of Health and other experts from the greater English and Scotch towns have told the Commission, with much self-gratulation, what has been done by them, and what, they think, ought to be done. The authorities have only to cram sanitation down the throat of the poor population of the city, and to extract the million of money which the process will cost from the pockets of the Dublin ratepayers, and all will be well. Dublin is grateful for the instruction, but feels compelled to decline it with thanks. The sanitation politics and

financial policy of wealthy English towns, dealing with a more or less cleanly and law-abiding poor population, does not touch the necessities of Dublin at any point, and the information afforded by these experts though interesting to the sanitarian, is of little practical use. The lowest class population of the city, whose chronic squalor, half starvation, and intemperance are the chief factors in the excessive mortality in Dublin, may be encouraged, educated, and persuaded, with a little firm pressure, to live more clearly and soberly, and the tenement farmers who draw their incomes from such people may be forced to reform the home conditions, but we are convinced that the present chance of radical improvement in Dublin would be lost if the inevitable panacea of these ultra sanitarians (*i.e.*, the policeman) is too much in evidence. Furthermore it is simple waste of speech for these sanitarians to tell the Dublin Corporation that no reform of sanitation can be effected without the outlay of half a million of money on palatial isolation hospitals and Rowton Houses. If such establishments are to be provided Dublin must be content to begin on the most moderate scale, and to look for the beneficial result years hence. Then, again, the Commission has, so far, been swamped by the evidence of amateurs and other sanitarians who volunteered their testimony, which has been useful because it has indicated unanimity as to the causes of Dublin insalubrity, but has, otherwise, thrown little light on the subject. The witnesses have sworn that slaughter-houses should not be located at the back door of a tenement house; that the emanations from the manure of reeking dairy yards ought not to enter our households through our drawing-room windows; that the refuse of ashpits should not be carted through the city at midday; that a sufficient organisation should be maintained to compel the owners and occupants of tenement dwellings to make at least a pretence of cleanliness, that infected patients should be provided with some accommodation which would prevent them developing the disease in the family circle or wandering about the city with it on them, and that the very poor should be given the chance of living decently in decent dwellings if they wish. The citizens of Dublin did not need a Lord Lieutenant's Commission come from the Castle to tell us all this, as every educated individual in Dublin has, for long years, known it well; but now that it has again been emphasised, the Commission may, we suggest, proceed with advantage to deal with these conditions in a practical way and in a way appropriate to the conditions of Dublin, and not to those of Manchester or Glasgow. It is for them to indicate what changes in the municipal or public law of the city are necessary to carry into effect a root and branch reform in the sanitary arrangements—to consider how the money needed is to be found in the most economical amount and easiest way—to devise methods by which the poor of the city may be wheedled into accepting improvement, and, above all

things, to take steps which may prevent the shelving of all propositions for change in the interests of the butchers, the dairymen, and the tenement farmers, and the publicans. To do this and, eventually, to educate the poor of the city into cleanliness and self-respect is "work for the Gods," and, if the Commission can only start that work it will have well justified its existence.

Failure of the Inebriates' Act.

It is a matter of regret that the special Act dealing with inebriates, from which so much was hoped, has hitherto failed in its purpose. The reason is that there are no homes to which habitual drunkards can be sent, so that the Act remains a dead letter for a good and substantial reason. Last week the drawbacks of this very undesirable state of matters were illustrated in a London Police Court, where a woman, a chronic inebriate, had been remanded several times in order to that a home might be found for her under the Inebriates' Act. The court missionary, who had endeavoured to find a home for the prisoner, reported the following communication from the Government Inspector under the Act. "Dear Mr. X—, I am afraid I cannot help you. Duxhurst is, I believe, full: Ashford, being Roman Catholic, is out of it; and Bristol won't take London cases into either of their reformatories. The London County Council's own place will not be ready till April." The deadlock thus disclosed was completed by the statement of the magistrate that, excluding Roman Catholics, there were only fifteen women in homes. The question naturally arises as to whose duty it is to provide the homes necessary under the Act. As matters stand there is an obvious opening for private enterprise in that direction, although for various reasons public institutions would be preferable. It is hardly to be hoped that the present Government will take the affair in hand, so that for the present temperance reformers will have to remain content with the potential benefits obtained in the Act. By the way, it will be interesting to ascertain what is the salary paid to Her Majesty's Inspector under the Inebriates' Act, for according to his own showing the post he holds must be a sinecure.

Vegetarianism v. Tubercle.

THE vegetarians are always ready to combat fiercely any fresh point that may tell against their particular views, a zeal that does them no discredit. They are now up in arms over the recent observation of Sir J. Crichton Browne to the fact that tubercle is common in herbivorous animals, such as cows, but is practically absent in carnivora. At the same time he laid great stress on the importance of discarding every part of an animal containing the specific bacilli. A correspondent of a Midland journal maintains that this advice involves an inconsistency "for the carnivore devouring the whole carcass goes free of consumption, yet man using flesh in his dietary (although selected after inspection), contracts it to such an extent that 40,000 of our population die from it every year." A little

further consideration is needed for these criticisms themselves. First of all tubercle is a disease of domesticated animals, but is extremely rare, or altogether unknown among wild animals being in a state of nature. It is only when cows and other animals are herded together under unhealthy conditions that they become infected with tubercle. Hence the carnivora that live on wild animals eat flesh that is not specifically infected with tubercle, and the reason of their immunity is clear. As to the latter part of the argument, it must be conceded that tubercle is undoubtedly spread by eating the flesh of tuberculous animals. That is a good reason for exterminating infected beasts, and for insisting on proper sanitary surroundings for our flocks and herds, but is it a sound argument against flesh-eating? The use of rye bread produces a certain amount of gangrene, but are we on that account to forbid mankind from eating any more bread made from that widely-distributed cereal? Further, bread generally, which is often made under most filthy conditions, is possibly the source of much disease; at any rate, the statement that baking does not sterilise bread, advanced some years since at the Bristol meeting of the British Medical Association, has not been hitherto contravened. Lastly, the writer in the *Birmingham Daily Post* appears to think that the inspection of meat in this country is trustworthy. Perhaps it may interest him to learn that in the opinion of most sanitary experts, where any system exists at all it is so perfunctory, inadequate, and empirical as to be a standing reproach to the public sanitary administration of the United Kingdom.

Influenza Scotched, Not Killed.

WHAT with wars and rumours of wars, the national attention is for the time being diverted from home matters. In this way the fact that influenza is still playing havoc in our midst appears to have well-nigh slipped out of the minds of those who are not in the grip of that remorseless malady. Yet the returns of the Registrar-General write high upon the wall a record that may well give pause to the careless optimism of the man in the street, of whom it was long ago pertinently remarked that "familiarity breeds contempt." In the last available return from Somerset House the deaths attributed directly to influenza in London numbered 52, as against 109, 63 and 74 in the three preceding weeks. It was also given as a contributory cause of six other deaths, compared with three previous returns of 15, 11, and 15 under that heading. To these figures must of course be added a certain proportion of deaths returned under respiratory diseases, but which should properly be referred to influenza. Some of our winter seaside resorts are full of the disease, to say nothing of many inland towns. The moral of it all is that anyone who thinks he has a severe cold should be careful to ascertain whether he is not really suffering from influenza. The treatment of the two conditions differs widely, and the mildest case of influenza demands the most skilled medical attention available. Before long it is to be hoped that our sanitarians will find out the

way in which the germs of this disastrous disease are spread far and wide over the face of whole continents.

Infectious Diseases Hospitals.

THE Belfast Corporation is engaged in administering to the Dublin Corporation just now a useful lesson how not to settle the vexed question of a hospital for infectious diseases. Belfast has selected a site which is distant between five or six miles from the opposite side of the city, and it proposes to outlay £45,000 in buildings to provide 150 beds at £300 a bed, and to add £2,000 for sinking fund, and £6,000 for maintenance, yearly, to the taxpayers' burthen. As it is declared that the building must be "something of which the city may be proud," we may reasonably assume that architects and builders will satisfy the Corporation by erecting elaborate Queen Anne mansions, which will run the ultimately outlay up to £10,000 or £12,000 a year. We trust that the Dublin Corporation will not postpone indefinitely the realisation of a scheme for isolation hospitals by following the example of Belfast. The Dublin citizens want a building which shall be available for the accommodation of the infected poor when epidemics occur, but they do not want it placed five miles from the city nor decorated to suit the æstheticism of architects. If such provision cannot be made on other terms Dublin will have to do without it.

Personation of Qualified Practitioners.

It may be in the memory of our readers that an unqualified person named Holland was last year detected in practising under the name of a registered practitioner named Nugent, who had emigrated and died, and whose diploma Holland rented from the widow at 3s. 6d. per week. This ingenious person had actually succeeded in inducing the Council to reinstate the name of Nugent on the *Register* after it had been expunged by the Council itself, and he was enabled to do this by means of a false affidavit sworn by his qualified assistant, to the effect that he (Holland) was Nugent, and no one else, for which offence the qualified assistant was also struck off the rolls. We note a somewhat similar case which came before a London Police Court last week, in which one Collins was prosecuted for practising in the name of "Dr. Washington Evans," of London, who had been dead since November last. When a detective for the General Medical Council addressed a letter to Evans asking advice, he was answered by the defendant in Evans's name, and it was confessed by him afterwards that the fraud was carried on for the benefit of the widow. Collins was fined £2 and £5 5s. costs.

A MOVEMENT for the establishment of a University in Hamburgh has been set on foot and seems likely to be realised. There are in the city a considerable number of scientific institutions which are under central control, and have been working in harmony for many years, and it only remains to combine them in the proposed University.

Her Majesty's Devotion to Her Wounded Soldiers.

WHEN the history of the present war in South Africa comes to be written, it may safely be asserted that one among its chief incidents to which special attention will be drawn will be the kindly, sympathetic, womanly interest which Her Majesty the Queen evinced in her wounded soldiers. Painful as it must be to our revered Sovereign at the evening of her life to learn of the sacrifice of life and the sufferings among the British troops at the seat of war, it is nevertheless plain that she has determined to do her share in testifying to the national appreciation felt for the gallant work of the Empire's sons. Could any spectacle be more fully illustrative of the Queen's devotion in this regard than that which occurred at Netley last week? The newspaper press reported that Her Majesty paid a visit to that institution, which lasted for three hours, and during that time took the opportunity of speaking a few kind words to every wounded soldier who had been admitted for treatment from South Africa. It must be conceded that such a kindly act as this, apart from the instinct which prompted it, was a feat of endurance of which the nation may be doubly proud, when it is recollected that it was performed by the Queen in her eighty-second year. It is largely by such acts as these that the Sovereign has from the commencement of her glorious reign bound up her life with that of her loyal subjects, and it is also such acts as these that the nation never forgets.

The Clinical Significance of Decubitus.

IN the observation of a patient suffering from some serious illness, the careful clinician cannot overlook the posture which the sufferer assumes. That is to say any diseases associated with the assumption of an almost characteristic posture by the patient, and in not a few instances this is helpful when the question of diagnosis is raised. Nevertheless it is remarkable how much variety exists in this regard, and how little has been the attention drawn to the subject. In an article by Dr. Affleck in the current number of the *Scottish Medical and Surgical Journal*, this subject is discussed from the point of view respectively of diseases of the respiratory system, diseases of the circulatory system, and diseases of the alimentary system, giving examples of decubitus in each. The paper is of special value inasmuch as it mainly deals with details which are not mentioned in text-books, and travels over ground which is seldom included even in clinical teaching.

Comforts for the Royal Army Medical Corps.

CONSIDERING the prominence which has been given to the gallant and devoted services rendered by the Royal Army Medical Corps in the South African campaign, it is somewhat surprising that it is not until the last few days that a movement has been set on foot to enable them to share in the distribution of "comforts" which a generous and patriotic public have freely contributed for officers and soldiers. No

doubt army surgeons do not stand in need of woollen socks and comforters, but their men are exposed to vicissitudes of climate and to the hardships inseparable from a campaign like the present fully as much as their combatant brethren; indeed, their work continues long after the ordinary soldier has put the rifle aside in favour of the toothpick or the night cap. We trust that the movement inaugurated at the Birmingham Medical Institute last week will meet with a generous response at the hands of the public, if only to encourage a very meritorious body of men to continue to discharge their onerous duties with a zeal equal to that displayed in the near past.

Swiss Medical Education and Degrees.

OUR readers are no doubt aware that Zurich and Berne Universities were the first in Europe to grant medical degrees to women, which they did about twenty years ago. These qualifications looked well on paper, and, as may be supposed, were not difficult to obtain in respect of either curriculum or examination, but, as far as Britain is concerned, they carried no professional privileges or prestige, although certain Colleges of Physicians accepted them as *ad eundem* for their final examination. It seems, however, that the very small expense of the Berne education has been too much for the unsophisticated Swiss, and to relieve them of this hindrance an old lady named Lenz has bequeathed the whole of her very handsome estate, near Berne, for the purpose of providing impecunious female students with the requisite education.

A Medical Slander Case.

A CASE of a kind which one cannot but regret to see in Court was tried last week at the Liverpool Assizes, in which Dr. Harris Philpots, of Orton, claimed damages from Dr. A. E. Davies, of Liverpool, for slander. It seems that these two gentlemen represented conflicting interests in some business concerning certain liabilities under the Workmen's Compensation Act. The Insurance Company having declined to pay Dr. Davies at the rate of a guinea a visit, this gentleman wrote to the secretary to the effect that their medical representative, the plaintiff in the present case, had tried to bribe him to betray his clients interests by suggesting that he should send in his bill to the Insurance Company. There does not appear to have been any ground for the statement, and at the suggestion of the judge, Dr. Davies unreservedly withdrew his allegations, whereupon the suit came to an end, but it would have been much more dignified if this course had been adopted before the case came into court.

THE latest suggestion for the treatment of chronic constipation in childhood is the administration of butter, which should be given in the natural state, and not in any vehicle. The dose, after the first month of life, is from one-half to a whole teaspoonful daily, increasing the quantity according to age.

The Popularisation of Cremation.

THE Corporation of Hull has inaugurated a movement which may ultimately bring about a revolution in the present method of the disposal of the dead in this country. We allude to their decision to popularise the system of cremation by reducing the fee, thus bringing this process within the reach of all classes. On payment of one guinea to residents, and three guineas to non-residents the Corporation have undertaken to carry out cremation of the dead in the city of Hull, this price will also include a plain urn and burial of the same. This movement inaugurated by the Hull Corporation is a step in the right direction. Cremation is undoubtedly a method of disposal of the dead which should be encouraged. So far, however, two drawbacks have hampered its progress. The first is that of sentiment, and this will probably for some time to come delay the general adoption of cremation. In the lower classes especially there is a great feeling in favour of a "beautiful" funeral; the trappings of woe are a service to the mourners, because of the display which is made of the means wherewith to pay for them. On the other, the cold, matter-of-fact, procedures associated with cremation are not such as to appeal to the feelings of those who look upon the pageant of a funeral in a family as of more importance than a marriage. The second drawback to cremation has been that of expense. The process has hitherto been a costly one, and, so far as the metropolis is concerned, no effort has been made to bring it within the reach of the classes. This is a mistake, for upon hygienic and sanitary grounds cremation is unquestionably the best method of the disposal of the dead. The late Sir Benjamin Richardson used to say that, from the point of view of the chemist, if this process were universally resorted to, the earth would be deprived of much of its ammonia from which nitrogen is evolved. But while no doubt this, in a measure, would be true, there is no reason to believe that the natural supplies of nitrogen would fail to fulfil the world's requirements in this respect.

The Mechanical Restraint of Lunatics.

ONE of the Commissioners in Lunacy, Dr. Needham, recently visited the Hampstead workhouse and found that the lunacy patients were at times subjected to mechanical restraint by means of belts and anklets. This infringement of the law was reported to the Local Government Board, with the result that the Guardians had received warning that the practice must forthwith be discontinued, and intimating that, failing compliance, steps would be taken to endorse the law. It has since transpired that the mechanical restraint was resorted to, forsooth, simply because the workhouse accommodation does not comprise a padded room. A less adequate excuse it would be difficult to imagine. Surely the Guardians are aware that a padded room is required by law, and is, therefore, a necessary adjunct to their institution? Why, then, should they shirk making legal provision for their lunatic inmates? It is reassuring to find that

the Local Government Board, through Dr. Needham, is alive to the duty of securing compliance with the law, and, under pressure, no doubt the recalcitrant Guardians will fall into line.

Soldiers' Teeth.

MR. WEIR, M.P., brought under the notice of the House of Commons, last week, the fact that a large proportion of the young men who offered themselves for enlistment, and who were passed as suitable, were afterwards rejected for bad teeth, and he asked the Education Department to provide dentists to supervise the dental condition of the boys attending the Board schools. Sir John Gorst, who answered him thought that the matter is one for the School Board, but we do not agree with him. If the purpose of the dental supervision is to preserve the rising generation in a condition suitable for military service, it is surely the business of the Government. In any case the cost of such supervision would be small, and the gain to the community outside the army great.

A. New Enterprise of the Liverpool School of Tropical Diseases.

NOT content with their enterprise in sending an expedition to Sierra Leone and the Gold Coast and Lagos, for the purpose of studying the malarial parasite, the Liverpool School of Tropical Diseases have now determined to send another expedition up the Niger, with the view of further investigating Major Ross's theory as to the transmission of malarial fever by means of the anopheles mosquito. Since the conditions of life on the oil rivers are somewhat different from those on other parts of the West Coast, it is hoped that this new expedition may yield valuable results.

The Royal Naval Medical Service.

IN introducing the Naval Estimates, Mr. Goschen last week stated that important changes in the Medical Service are impending. The number of the higher ranks of officers is to be increased and arrangements are being made to afford the junior officers increased opportunities for study at Haslar and at medical schools. A professor of tropical diseases is to be appointed for Haslar, and prizes are to be awarded to officers at the end of their period of study there.

Army Medical Instruments.

IT was announced by Mr. Goschen last week, when introducing the Naval Estimates, that a full allowance would be made, in future, to Medical Officers for their instruments. Heretofore these officers have had to "provide themselves" with instruments, and complaints have been made to the Admiralty that the supply has, in consequence, been rather stinted.

IT is stated that even including deaths from typhoid and dysentery in the besieged towns the total mortality from disease in connection with the war in South Africa does not exceed 600, to which, however, must be added a very much larger

number of deaths from wounds. This compares favourably with the experience of the United States Army in the Cuban campaign, where a fifth of all the soldiers in the principal camps contracted typhoid, and 7 per cent. of them died. It must be borne in mind, however, that the climate of Cuba is probably less congenial to the Anglo-Saxon temperament than that of South Africa, and it is hardly fair, moreover, to compare an old-established service like ours with the improvised medical service of the American Army Department.

AT the annual meeting of the Royal Medical and Chirurgical Society the president, Mr. T. Bryant, before opening the proceedings, remarked that if he were not presiding at a scientific society he would be tempted to ask the Fellows for three cheers in honour of the news from South Africa, a hint which the Fellows were not slow to act upon. It was evident that the feeling of satisfaction is not less keen among members of the profession than in the general public, though expressed in a less boisterous fashion—indeed members of the profession play too prominent a part in what Mr. Bryant elsewhere alluded to as “this miserable war” for their fellows to remain indifferent to their success.

ACCORDING to Dr. Clouston, superintendent of the Royal Edinburgh Asylum for the Insane, the proportion of cases of insanity directly attributable to alcohol, is 25·25 per cent., exactly the same proportion as that of the last five years. He remarked incidentally that the influenza was responsible for more cases of insanity than the emotions caused by the war and private losses put together.

NEW naval sick quarters, with a dispensary, are to be provided at Woolwich at an estimated cost of £12,000.

PERSONAL.*

SIR WM. MACCORMAC left Cape Town on Saturday last on the return journey.

CAPT. C. A. MAUNSELL, R.A.M.C., Administrative Medical Officer in Bombay, has been appointed Principal Medical Officer of the South-Eastern District.

DR. C. THEODORE WILLIAMS has been elected president of the Meteorological Society which this year celebrates its jubilee.

DR. SIDNEY RINGER, senior physician, and Mr. Christopher Heath, senior surgeon, to University College Hospital, will retire shortly in virtue of the age limit.

DR. JOSEPH HUNTER, one of the resident physicians in the Royal Infirmary, Edinburgh, has been accepted by the War Office as a civil surgeon, and starts for South Africa in a few days.

PROF. THOMAS JONES, M.B., F.R.C.S., of Manchester, has offered his services, which have been accepted by the authorities, to the Welsh Military Hospital, which is being established in South Africa.

MR. R. J. BREW, Superintendent of the administrative accounts in the office of the Registrar-General in Dublin, and second in command to Mr. M. Matheson, lately appointed as Registrar-General, has been appointed Assistant Registrar-General in his place.

HER Majesty the Queen personally bestowed on Thursday last the decoration of the Order of St. Michael and St. George upon Dr. Patrick Manson, Medical Adviser to the Colonial Office.

MR. VICTOR HORSLEY availed himself of the opportunity afforded by the dinner given by the Medical Society of Edinburgh yesterday (Tuesday) to deliver a speech on “The Medical Corporations.” We are not in possession of the terms of his remarks, but we can guess their tenour.

MR. ROBERT IRVINE, M.B., senior demonstrator of anatomy, Surgeons’ Hall, Edinburgh, who was lately accepted by the War Office for service in South Africa, was presented last week with two cases of surgical instruments on behalf of Dr. Whitaker and the students of the Anatomy Class at Surgeons’ Hall.

IN connection with the death of Dr. Wm. MacNeill Whistler, physician to the London Throat Hospital, which occurred in London last week, it will interest many to know that he was a surgeon in the Confederate Army during the American Civil War, and possessed both English and American diplomas.

ON the Queen’s visit to Netley Hospital last week, she was conducted through the wards and divisions by Major W. Dick, M.B., and Lieut.-Colonel W. E. Webb, M.D., Assistant Professors of Military Surgery and Medicine. Her Majesty spoke to the sick and wounded men, and made presents of flowers to those who were confined to their beds.

Scotland.

[FROM OUR OWN CORRESPONDENT.]

EDINBURGH’S WAR HOSPITAL.—Towards the £20,000 aimed at towards the formation of this hospital, £18,105 have been subscribed. Professor John Chiene, of the Edinburgh University has been offered and has accepted the post of civil surgeon in charge, and will be accompanied by his assistant, Mr. David Wallace, M.D., as second surgeon. Several junior Edinburgh men will form the staff, including Dr. George Chiene, the professor’s son. Professor Chiene’s resolve to serve his country at the seat of war on request is only what all who know him might have expected, and will assure the greatest possible efficiency in the surgical work of the hospital.

THE CHAIR OF PRACTICE OF PHYSIC IN EDINBURGH.—The question of who is to be the next occupant of the Chair of Cullen, Gregory, Alison, and other distinguished teachers of medicine continues to occupy the minds of the profession in Edinburgh. That Professor Osler has been approached in connection with the vacancy is generally an accepted fact, but how is he to act unless he enters as a candidate in the regular way is difficult to understand. The Curators of Patronage can hardly, in face of the standing of the other applicants, offer the post to one outside their ranks. Dr. Byrom Bramwell has distributed to members of the profession in Edinburgh, or connected with her school, copies of his letter of application, a wonderful record of work done, the sum of his published books and papers well-nigh reaching 200.

INFLUENZA IN EDINBURGH.—Influenza is still very prevalent in Edinburgh. A noteworthy fact about the present epidemic is the predilection the disease has shown for attacking the well-to-do classes. Not one case has been detected in any of the common lodging-houses in the city, while for some time after the commencement of the epidemic all the fatal cases which occurred were recorded in the south side suburbs, which are largely composed of villas and private houses. Latterly the West End has suffered, but the poorer parts of the city have experienced an almost complete immunity. Conversely, in several of the Infirmary wards patients of the class which has escaped outside have in many instances been attacked by the scourge while under treatment for other disease. Among members of the medical profession, Drs Muirhead, Watson, and P. MacLaren, and Professor Fraser, have all passed through more or less severe attacks, but have now, it is gratifying to be able to report, recovered or are convalescent.

EDINBURGH STUDENTS AND THE WAR.—The residents in the Edinburgh Infirmary have lost four of their number for service at the Cape in various posts. The equipment of the City War Hospital promises to detach others. Dr. Donald, a former Edinburgh University athlete, who was in practice in the city, has just left for South Africa, his services having been accepted by the War Office.

Obituary.

DR. BROOM, OF CLIFTON.

WE regret to announce the death of Dr. John Broom, at his residence Clifton, Bristol. Leaving a large and successful practice in Sheffield, he went to Clifton on account of his health in 1877. In 1883 he established the Bristol Institution for Skin and General Diseases, then in Nicholas Street. He was a Brussels graduate, holding also the L.R.C.P.I., and the L.R.C.S.Ed. Of attractive manners, he was popular both with his professional brethren and with his patients, by whom he will be greatly missed.

Literary Notes and Gossip.

THE *Archives of Pediatrics* will in future be edited by Dr. Walter Lester Carr, of New York, in whose hands a more successful career is anticipated for this publication.

A NEW edition of "Kirke's Physiology," edited by Dr. Halliburton of King's College, has just made its appearance. We are asked to announce that Dr. Ireland is preparing a new edition of his book on "The Mental Affections of Children."

A VERY pronounced effect of the war in South Africa is the paucity of new works in medicine and allied sciences. The autumn and winter, which is usually regarded as the season proper, has proved almost barren of new books, and we understand that with the exception of war literature there is absolutely no demand for books of any kind, so that publishers and the profession alike are suffering coincidentally with the nation at large.

IT is interesting to note that the word "Immune," which is included in the latest edition of the new "English Dictionary of Historical Principles," has been in use for six hundred years, although it is brand new in medical use. There is one class of old English words which has almost disappeared in this section, namely, the compounds in "i." In southern English they survived to the 15th century, when they were usually spelt with "y"—in which guise, "y-clad," "y-clept"—were handed down by the Elizabethan archaists.

THE eighth edition of Dr. Macnaughton-Jones's "Diseases of Women and Uterine Therapeutics" is announced to appear in a few days. We understand

that the work has been entirely re-cast, and is being issued in quite a new form. The rapid advances made in gynecology since the last edition appeared, have compelled the author to make considerable alterations, both in regard to discarded views and operations, as well as in view of the many important advances that have been made, especially in the field of operative gynecology. The book has been newly illustrated, and all the most recent models of instruments and appliances are figured.

THE first number, dated February 15th, has been issued of a new "Bibliographica Medica," devoted to the international bibliography of medical sciences on the model of the defunct "Index Medicus." The compilation will be edited by Professors C. Potain and Ch. Richet, of Paris, whose names afford some guarantee of accuracy and scientific method. The publication is to be issued monthly, like the "Index Medicus," and each number will contain a minimum of 4,000 references. The subscription has been put at 60 francs for foreign circulation (outside France) a figure which compares favourably with the £5 formerly charged for the American publication. We wish the venture every success and we regard the moderate cost as an important factor in securing it.

DR. ROBERT BELL, of Glasgow, has not been always fortunate in his relations with his brethren. He has now evolved a new idea, and has issued a book entitled "The Deputy Physician," for the benefit of the public at large. The medical journals are not honoured by receiving copies for review, and we know only of its existence from criticisms in the newspapers. Here is the opinion of the *Daily Chronicle* on the author's latest literary effort:—"This is a bad specimen of a bad class of book, and we fear that we cannot even endorse the author's description as given on the title-page, for it is not a guide to health, but rather an encouragement to tamper with health. In discussing the majority of his fellow-doctors, the author remarks that a little knowledge is a dangerous thing, and then at once proceeds to impart rather less than a little to the public, for whom the book is avowedly written."

NEW BOOKS AND NEW EDITIONS.

THE following have been received for Review since the publication of our last monthly list:—

BAILLIERE, TINDALL, COX, AND CO. (London and Paris.)

Treatise on Orthopaedic Surgery. By Ed. H. Bradford, M.D., Professor of Orthopaedic Surgery in Harvard University, and Robt. W. Lovett, M.D. Second Edition, with 621 illustrations. 655 pp. Price 18s.

Aids to Practical Pharmacy for Medical Students. New and revised edition. By A. Campbell Stark, Demonstrator of Materia Medica and Pharmacy at St. George's Hospital. Pp. 170. Price 2s. 6d.

Cancer et Tuberculose, par le Dr. Henri Claude. Pp. 94. Price 1s. 6d. cloth.

CHARLES GRIFFIN AND CO. LIMITED (London.)

The Flowering Plant as illustrating the First Principles of Botany. By J. R. A. Davis, M.A. F.C.P. 3rd Edition. Pp. 195. Price 3s. 6d.

HY. J. GLAISHER (London.)

Consumption: Its Nature and Treatment. By W. J. Spencer, M.A. M.D., M.R.C.P. Pp. 83. Paper cover.

H. K. LEWIS (London.)

A Manual of Gynecological Practice. By Dr. A. Dührssen, Professor of Midwifery, Univ., Berlin. Translated by John W. Taylor, F.R.C.S., Professor of Gynecology, Masons College, Birmingham, and Frederick Edge, M.D., Lond. F.R.C.S., Pp. 279.

Mentally Deficient Children. By G. E. Shuttleworth, B.A., M.D., 2nd Edition. Pp. 180. Price 5s. net.

LONGMANS, GREEN, AND CO (London.)

A Manual of Pathology. By the late Joseph Coats M.D. Fourth Edition, revised by Lewis R. Sutherland, M.B., Professor of Pathology in the University of St. Andrews. Pp. 1132. Price 31s. 6d.

SMITH, ELDER AND CO. (London.)

Saint Bartholomew's Hospital Reports. Vol. XXXV. Edited by Norman Moore, M.D., and D'Arcy Power, F.R.C.S. Pp. 246 and 356.

Literature.

SAVILL ON NEURASTHENIA. (a)

WE have here collected lectures delivered at the Paddington Infirmary and at Welbeck Street Hospital for Diseases of the Nervous System. The first lecture is largely taken up with a description of the general clinical material presented within the wards of a Poor-law infirmary. Undoubtedly, the opening of the Poor-law infirmaries of the Metropolis for clinical instruction with an aggregate of over 13,000 beds, is a step of immense significance in medical teaching, and Dr. Savill does well to recapitulate the very interesting types of disease there presented, and certain advantages here obtained over general hospitals and asylums. There is always the danger, however, that in making comparisons one may unduly exaggerate on one side or other; and when the author claims for the lunacy wards unique opportunities for the study of the beginning of mental alienation, we are afraid he is speaking rather late in the day, for the beginnings of mental alienation go further back. To say also that only chronic insanity can be studied in lunatic asylums is absurd. What about the cases which recover? With the remarks on specialism, methods of research, and clinical investigation, we have nothing to say. They are merely introductory. On the subject of the pathology of functional disorders of the nervous system the author gives six different ways in which they may be explained, and we are pleased to observe that he regards his views as largely a matter of hypothesis. We quite endorse his opinions that the term *hysteria* is too widely and indiscriminately used. The author does not believe in conscious, wilful stimulation of organic nervous disease, and he speaks from an extensive acquaintance with workhouse hospital cases and assures us that hysteria is quite as frequent among the poor and ignorant as among the wealthy and intelligent. The author's distinction between hysteria and neurasthenia will be found very helpful as a good deal of doubt and confusion prevails respecting this point. The succeeding lectures deal with the diagnosis and the pathology of neurasthenia, the mental symptoms of neurasthenia and neurasthenic insanity. There is much that is vague and indefinite in these lectures and a use of terms which we cannot reconcile with our experience. We had hoped to learn something new in regard to the relations of neurasthenia and insanity, but we confess to being disappointed. The author has, however, given some interesting clinical cases, and these speak for themselves. If they had been more succinctly stated and classed together apart from the general text, they would be useful as references for busy medical men. These lectures have diligently grappled with a difficult subject.

LES ARMES BLANCHES. (b)

THE two army surgeons, the authors of this work, have compiled a very practical as well as scientific account of wounds produced by "cold steel." The cavalry sabre is taken as the type of a cutting weapon, and the wounds it may cause in various regions and to different tissues are fully described, many cases being quoted in illustration. The remainder of the book is devoted to pointed weapons. First the bayonets of different nations are described, then a long, exhaustive account is given of the wounds they may cause in all parts of the body, together with the diagnosis, prognosis, treatment, &c., of such wounds; next, the lesions produced by the point of the infantry sword, by the duelling sword, and by the lance are considered; a brief chapter is devoted to wounds made by poisoned arrows, upon which some hints are given which would prove of great use in savage warfare. The book terminates by a few words about defensive armour; the helmet and the cuirass are only mentioned as relics of the time when battles were decided with

(a) "Clinical Lectures on Neurasthenia." By Thomas D. Savill, M.D. London: Henry J. Glaisner. 1899.

(b) "Les Armes Blanches, leur action et leurs effets vulnerants." By Drs. Nimier and Ed. Laval. Paris: Felix Alcan, Editeur. P. 435.

"cold steel," but mention is made of the modern idea consisting of a metal screen giving a more or less certain shelter from bullets. There is no doubt that all naval or military surgeons having a knowledge of French would find a great amount of interest and instruction in the pages of this book.

Laboratory Notes.

CHINOSOL TABLETS.

THE antiseptic and deodorant properties of chinisol in surgical practice and general hygiene are pretty generally recognised and appreciated, but its value as an internal antiseptic is less known. We have been favoured by Mr. Kühn with a sample of the five-grain Chinisol Tablets which are especially intended for internal administration. Given the well-authenticated antiseptic and anti-fermentative potency of this substance, and in view of its innocuousness and absence of causticity, we can quite imagine that its effects in arresting gastro-intestinal fermentation would be marked. In typhoid fever the benefits to be derived from an anti-putrefactive medication are well known, and the special properties of chinisol seem to mark it out for a careful trial on these lines. The dose of chinisol for internal administration is five grains three times daily, taken either dissolved in water or (crushed) in cachet form.

Added to impure water it effectually destroys pathogenic organisms, but in view of the announcement that a large supply of the tablets has been sent to Durban, we doubt whether the average British soldier will consent to "chinolise" his drinking water merely to avoid typhoid fever or dysentery.

CHLORETONE.

CHLORETONE, the new hypnotic, analgesic and anæsthetic, introduced by Messrs. Parke, Davis and Co., is a fine white crystalline compound resulting from the interaction of chloroform, acetone and an alkali. It is sparingly soluble in cold water, but is very stable. The average dose is from 6 to 18 grains, preferably given in cachets or in the form of sugar-coated tablets, each of which contains three grains. A saturated solution of chloretone, used in the same way as cocaine and eucaine, exerts similar anæsthetic properties. Experimentally, in animals, it has been successfully employed as a general anæsthetic, the quantity required being about 3½ grains per kilogramme of body weight. This application does not appear to have been so far tried on human beings. It is specially recommended in the treatment of insomnia, and as an analgesic in gastralgia and vomiting. It is stated not to depress the circulation "materially," even in comparatively large doses, and its action is claimed to be restricted to the cortical nerve cells.

Medical News.

Dublin Health.

THE death-rate of Dublin, which had fallen to 29.1 per 1,000 of the population, has risen again to 51.0. This apparently heavy increase has arisen from the inclemency of the weather, which has run up the deaths from respiratory disease to a phenomenal number, 94 of such deaths are recorded, being 37 above average, and 20 above last week. It is also pointed out that the figures for this week are made to look much worse by the neglect of the authorities of the South Dublin Union to register their deaths in due time. No less than 51 of the deaths now registered occurred in the workhouse before February 17th.

St. Thomas's Hospital House Appointments.

THE following gentlemen have been selected as house officers from Tuesday, March 6th, 1900:—

House Physicians: H. R. Beale, L.R.C.P., M.R.C.S., L. S. Dudgeon, L.R.C.P., M.R.C.S., B. F. Howlett,

L.R.C.P., M.R.C.S. (extension), and F. H. Ellis, B.A., M.B., B.C., Cantab., L.R.C.P., M.R.C.S. (extension).

Assistant House Physicians: E. W. Hedley, M.A., M.B., B.C., Cantab., and F. C. Eve, B.A., M.B., B.C., Cantab.

House Surgeons: A. Webb Jones, L.R.C.P., M.R.C.S., E. A. Gates, L.R.C.P., M.R.C.S., E. C. Bourdas, L.R.C.P., M.R.C.S., and N. Unsworth, L.R.C.P., M.R.C.S.

Assistant House Surgeons: A. E. Martin, B.A., M.B., B.C., Cantab., L.R.C.P., M.R.C.S., J. F. Cunningham, L.R.C.P., M.R.C.S., and Y. Takaki, L.R.C.P., M.R.C.S.

Obstetric House Physicians: (Senior) H. H. R. Clarke, L.R.C.P., M.R.C.S., and (Junior) A. Bevan, L.R.C.P., M.R.C.S.

Ophthalmic House Surgeon: (Senior) J. E. Kilvert, L.R.C.P., M.R.C.S.

Clinical Assistants in the Special Department for Diseases of the Throat: S. H. Belfrage, M.B.Lond. (extension), and S. A. Lucas, L.R.C.P., M.R.C.S. Skin: R. B. Kinloch, L.R.C.P., M.R.C.S., and J. C. W. Graham, B.A., Cantab., L.R.C.P., M.R.C.S. Ear: G. I. T. Stewart, M.A., M.B., C.M., Aberd.

Medical Defence Union.

THE Annual General Meeting of the Medical Defence Union will be held on Tuesday, March 13th, at St. Martin's Town Hall, W.C., at 4 p.m. The chair will be taken by Dr. Griffith, F.R.C.P., the President of the Union.

Royal Medical and Chirurgical Society of London.

At the Annual General Meeting, on Thursday, March 1st, the following were elected officers for the ensuing year:—

As President: Frederick William Pavy, M.D., F.R.S.

As Vice-Presidents: Sydney Ringer, M.D., F.R.S., Charles Theodore Williams, M.D., Henry Greenway Howse, M.S., Henry Morris, M.A., M.B.

As Honorary Treasurers: William Selby Church, M.D., J. Warrington Haward.

As Honorary Secretaries: Thomas Barlow, M.D., Alfred Pearce Gould, M.S.

As Honorary Librarians: Norman Moore, M.D., Rickman J. Godlee, M.S.

The Medical Sickness and Accident Society.

THE usual monthly meeting of the Medical Sickness Annuity and Life Assurance Society was held at 429, Strand, London, W.C., on February 23rd. There were present Dr. de Havilland Hall, chairman; Dr. J. B. Ball, Dr. Walter Smith, Mr. F. S. Edwards, Dr. J. Pickett, Mr. William J. Stephens, Dr. M. Greenwood, Mr. J. Brindley James, Dr. J. W. Hunt, Dr. W. Knowsley Sibley, and Mr. Edward Bartlett. As is usual at this time of the year, the list of current sickness claims was very long. A large number of the illnesses have been caused by influenza and by the bronchial affections which are so prevalent in the early spring, and to which medical men, especially those in country practice, are particularly liable. About one-third of the whole number of current claims are cases in which there is little hope that the members will be ever again able to resume practice. In these cases the continuous half-pay of the society forms a very valuable provision. Prospectuses and all particulars on application to Mr. F. Addiscott, sec., Medical Sickness and Accident Society, 33, Chancery Lane, W.C.

THE annual general meeting of the Irish Medical Schools' and Graduates' Association will take place at the Hotel Cecil on March 17th, at 6.30 p.m., and on the same evening the Association will dine at 7.15. Inspector-General W. H. Lloyd, M.D., in the chair.

The Viavi Fraud.

AN inquest was held at Eastbourne a few days since on a young married woman who had died somewhat suddenly after taking the remedies of a commercial concern known as the "Viavi" Company. It transpired that death was due to the rupture of a duodenal ulcer, but the jury, in returning a verdict of death from natural causes, added an expression of opinion, based on the evidence given before them, that the "Viavi" Company was a fraud. A "Dr." Woodward, who claims to

hold a medical qualification granted by the University of Pennsylvania, stated that he was the "overseer" of the medical department of the company.

University of Durham Faculty of Medicine.

THE Secretary of State for War, having availed himself of the powers conferred upon him by Royal Warrant, recently offered to the University of Durham three nominations to the Royal Army Medical Corps, which have been filled by the following gentlemen:—Mr. James Andrew Hartigan, Mr. Charles S. Smith, and Mr. Harold Ben Fawcett, all of whom are graduates in medicine and surgery of the university. It may be also mentioned that Surgeon-Captain Marford, who accompanies the South African Battery of the 1st Northumberland Volunteer Artillery, and Surgeon W. L. W. Walker, who has been attached to one of the South African Companies of the Northumberland Yeomanry are also graduates of Durham. Of the present and former students of the University of Durham College of Medicine, eight have volunteered for service in South Africa, and are either at the front or on their way there.

Royal Army Medical Corps.

MR. POWELL WILLIAMS, in reply to Captain Norton, who suggested the advisability of organising a special staff of night orderlies, who would be excused day duty as in all large civil hospitals, in order that the sick or wounded soldier might be at least as well attended to as the civilian patient, said that the question had been very carefully considered, and in view of the number of experienced men of the Medical Staff Corps, who have applied to re-enlist, and by whose help the pressure will be greatly diminished, it is not thought expedient to form the special staff suggested.

THE Church Missionary Society has received an anonymous donation of £8,000, one-fourth of which is to be expended on medical missions.

THE death is announced of Thomas Guy, M.D., F.R.C.P., Inspector-General of Army hospitals, in his 81st year. His father and grandfather were both members of the medical profession, and he was the brother of Dr. William Guy, F.R.S. Dr. Guy, in 1870, translated into English Esmarch's "First Dressing of Wounds on the Battlefield."

Vital Statistics.

THE deaths registered last week in thirty-six great towns of England and Wales corresponded to an annual rate of 27.5 per 1,000 of their aggregate population, which is estimated at 12,784,802 persons in the middle of this year. The deaths registered in each of the last four weeks in the several towns, alphabetically arranged, corresponded to the following annual rates per 1,000:—

Birkenhead 24, Birmingham 22, Blackburn 37, Bolton 24, Bradford 21, Brighton 23, Bristol 18, Burnley 29, Cardiff 13, Croydon 9, Derby 22, Dublin 51, Edinburgh 25, Glasgow 35, Gateshead 23, Halifax 26, Huddersfield 21, Hull 22, Leeds 29, Leicester 20, Liverpool 33, London 21, Manchester 34, Newcastle-on-Tyne 25, Norwich 25, Nottingham 21, Oldham 33, Plymouth 27, Portsmouth 18, Preston 44, Salford 39, Sheffield 27, Sunderland 22, Swansea 17, West Ham 17, Wolverhampton 40.

Her Majesty's Navy Medical Service.

THE undermentioned gentlemen, who competed on February 19th, 1900, and following days at Examination Hall, Victoria Embankment, for appointment as Surgeon in the Royal Navy, have been granted commissions:—

MR. W. A. SMITH.—Your faith in the drug you mention as a remedy for whooping cough may or may not be well founded. In other words, your experience may be such as to furnish good ground for inference or rational belief. Whether the causal sequence will hold good or otherwise upon further consideration is for you to examine for yourself. Before you can expect any scientific body to accept your conclusions, however, we need hardly remark that you will have to prove your position to full demonstration. You will have, for instance, to produce a number of cases so large as to exclude mere coincidence in the cures. Cases will also be required treated by other methods, and, if available, those treated without drugs. If, after most searching examination, you can demonstrate that the administration of your new remedy, and the cure of whooping cough stand in the relation of cause and effect you will have conferred a benefit upon humanity, and will be justified in publication.—*Festina lente.*

E. T. R.—Sharp pain at the instant of ejaculation may be due to impingement of the semen upon the mouth of the duct, pathologically narrowed by posterior gonorrhoeal urethritis, but the presence of a congestive stricture in the penile urethra will also give rise to pain, localised to the strictured part. In some cases the narrowing of the ejaculatory duct may be so marked as virtually obliterate the passage, and, if bilateral, sterility is the result.

JAPAN TO THE FORE IN TUBERCULOSIS?

We cull the following from a recent number of the *Sei-Kwai* medical journal, in the English language of that journal:—"Fleet-Surgeon T. Yabe, of the Imperial Japanese Navy, who is now studying bacteriology in the Pasteur Institute, Paris, discovered some method to make human subjects *immune from the tubercular disease* with some material which he calls *Tuberculo-Immunitine*. We heartily congratulate his success for such great and difficult subject which was considered almost impossible to achieve at among the imminent authorities in Europe and America."

Meetings of the Societies and Lectures.

WEDNESDAY, MARCH 7TH.

OBSTETRICAL SOCIETY OF LONDON.—8 p.m. Specimens will be shown by Mr. G. W. B. Lawrence (introduced by Dr. Blacker). Dr. Macnaughton-Jones, and others. Demonstration:—Mr. A. Keith (introduced by Dr. Lewers): Dropsical Parasitic Twin Fetus of Peculiar Form. Paper:—Dr. J. Phillips: A Case of Extra-uterine Gestation in which Fetal Death occurred at Term after Spurious Labour and Abdominal Section was performed from four to five months later.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—4 p.m. Prof. A. W. Mayo Robson: The Surgery of the Stomach.

THURSDAY, MARCH 8TH.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.—8 p.m. Cases and Card Specimens. 8.30 p.m. Papers:—Mr. W. M. Beaumont: Family Tendency to Ophthalmoplegia Externa.—Mr. A. Q. Silcock: Meningitis followed by Panophthalmitis.—Mr. J. H. Fisher: Pigmented Tumour of the Eyeball, Death from Multiple Pigmented Carcinomata nearly 14 years after Excision of the Eye.—Mr. H. W. Dodd: Green Vision.—Mr. W. H. Jessop: Embolism of both Central Retinal Arteries.

MEDICAL SOCIETY OF LONDON (Whitshall Rooms, Hotel Metropolitan).—7 p.m. Anniversary Dinner.

BRITISH GYNECOLOGICAL SOCIETY (20, Hanover-Square, W.).—Specimens will be shown by Mr. S. Bishop, Dr. G. Elder, and Dr. Macnaughton-Jones. Papers: Dr. R. Worrall: Pregnancy complicated with Myomata and Ovarian Cyst.—Dr. M. Laurie: The Indications for the Removal of the Uterine Appendages.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—5 p.m. Dr. F. J. Waldo: Summer Diarrhoea with special relation to Causation and Prevention. (Milroy Lecture.)

FRIDAY, MARCH 9TH.

CLINICAL SOCIETY OF LONDON (20, Hanover-Square, W.).—8.30 p.m. Papers:—Dr. Caton: The prevention of Valvular Disease in Acute Rheumatism.—Dr. Hale White and Mr. Frigg: A Case in which the attempt was made to Remove a Dermoid Tumour which, growing in the Spinal Canal, pressed upon the Spinal Cord.—Dr. F. E. Batten and Dr. Prickett: A Case of Acute Encephalitis in a Child following Infantsia.

BRITISH LARYNGOLOGICAL, RHINOLOGICAL, AND OTOLOGICAL ASSOCIATION (11, Chandos Street, Cavendish Square, W.).—4.30 p.m. Discussion on Condition of the Throat and Larynx Simulating and Predisposing to Tuberculosis (opened by Mr. Lennox Browne).

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—4 p.m. Prof. A. W. M. Robson: The Surgery of the Stomach.

ROYAL INSTITUTION OF GREAT BRITAIN.—9 p.m. Prof. F. Clowes: Bacteria and Sewage.

SATURDAY, MARCH 10TH.

ROYAL INSTITUTION OF GREAT BRITAIN.—3 p.m. Right Hon. Lord Rayleigh: Polarised Light.

Appointments.

DUNLOP, THOMAS, M.B., C.M. Edin., D.P.H. Camb., Medical Officer of Health to the Aldershot Urban District.

HEBBLETHWAITE, ALFRED G., M.R.C.S., L.R.C.P. Lond., appointed Public Vaccinator for Keighley and District.
LIMINGTON, W. W., F.R.C.S. Eng., Honorary Assistant Medical Officer to the Victoria Hospital, Folkestone.
O'BRIEN, D. P., L.R.C.P. Irel., L.R.C.S., F.R.C.S., Irel., Government Medical Officer at Ravenswood, Queensland.
STEGMANN, ED. J., M.B., D.P.H., Assistant Lecturer on Hygiene and Public Health at St. Mary's Hospital Medical School, London.
VICKERS, CHARLES W., M.R.C.S., L.R.C.P. Edin., L.S.A., D.P.H. Lond., Medical Officer of Health for Paignton (Devonshire).
WAUGH, J., M.D. Dub., Medical Officer for the Leighton Buzzard Union.

Vacancies.

Cardiff Infirmary.—Resident Medical Officer. Salary £100 per annum, with board, washing, and apartments. Also an Assistant House Physician for six months. Salary at the rate of £50 per annum, with board, washing, and apartments.
Castleberg Union. Medical Officer. Salary £100, and £15 per annum as Sanitary Officer, with the usual Vaccination Fees. Applications to W. Hamilton, Clerk of the Union. (See Advt.)
Cumberland and Westmorland Asylum, Garlands, Carlisle.—Junior Assistant Medical Officer, unmarried. Salary £100 a year, with board and residence.
Devon County Asylum, Exminster.—Third Assistant Medical Officer. Salary £100, rising to £125, with board and residence.
Durham County Asylum.—Assistant Medical Officer. Salary, commencing at £140, with board, lodging, washing, &c. Apply to Medical Superintendent, Winterton, Ferryhill.
Great Northern Central Hospital, Holloway, London.—Junior House Surgeon for six months. Salary at the rate of £30 per annum, with board, lodging, and washing in the hospital. (See Advt.)
Hants County Asylum, Fareham.—Third Assistant Medical Officer, unmarried. Salary commencing at £125 per annum, with apartments, board, washing, and attendance.
King's College, London.—Professorship of Materia Medica and Therapeutics.
Newport and Monmouthshire Hospital, Newport, Mon.—House Surgeon. Salary £100 per annum, with board and residence. No stimulants provided.
Nottingham General Hospital.—Assistant House Physician for twelve months. Salary £100, with board, lodging, and washing in the hospital.
Royal Surrey County Hospital, Guildford.—House Surgeon and Assistant House Surgeon. Salary, House Surgeon, £80 a year, with board, residence, and laundry. Salary, Assistant House Surgeon, £30 a year, with board, residence, and laundry.
Royal National Hospital for Consumption, Ventnor, Isle of Wight.—Resident Medical Officer. Salary £150 per annum, with board and lodging, and the assistance of a clinical assistant and a dispenser. Immediate applications to Dr. Parry at the Hospital. (See advt.)
Sheffield Royal Hospital.—Two Assistant House Surgeons (Senior and Junior), unmarried. Salary £50 each per annum, with board (exclusive of wine and beer), washing, and lodging.

Births.

HINDS.—On March 1st, at 14, The Steyne, Worthing, the wife of Frank Hinds, M.D., of a son.
WICKHAM.—On Feb. 25th, at Chernock House, Fleet, Hants, the wife of Gilbert H. Wickham, M.B. Cantab., of a son.

Marriages.

FESTING-SMITH—DE COURCY.—On Feb. 27th, at St. Stephen's-by-Saltash, Alfred C. Festing-Smith, L.R.C.P., F.R.C.S., of St. Budeaux, to Esther Eleanor, eldest daughter of Lord and Lady Kingsale, of Stoketon, Saltash.
GRIFFITH—WELCHMAN.—On Feb. 27th, at Cullompton, Alfred Hume Griffith, M.B., Ch.B., second son of the late Rev. E. Moule Griffith, B.A., to Mary Eliza, only daughter of George Welchman, Esq., of Cullompton.
HOLLIS—LASSELL.—On Feb. 27th, at St. John's Wood Presbyterian Church, Harry Hollis, M.D. Cantab., of Wellingborough, to Eleanor, third daughter of the late William Lassel, jun., of Liverpool.
MOLONY—HIGGINSON.—On Feb. 27th, at Great Connell Church, Kildare, John Molony, F.R.C.P., son of the late Charles B. Molony, Esq., to Mary Macaulay (May), second daughter of the late Charles H. Higginson, Esq., of Springmount, co. Antrim.
STOWE—BROWNE.—On Feb. 27, at St. Paul's, Wellington, New Zealand, by Bishop Wallis, W. Reginald Stowe, M.R.C.S.E., eldest son of Leonard Stowe, of Tikiwai, Wellington N.Z., to May, eldest daughter of Wm. Lyon Browne, of Church Stretton, Shropshire.

Deaths.

DUKE.—On Feb. 22nd, at Villa Albert, Cannes, Frank Douglas William Duke, M.R.C.S., aged 51.
GUY.—On March 2nd, at Dover, Thomas Guy, M.D., F.R.C.P., Inspector-General of Army Hospitals (retired), in his 81st year.
HEATHER.—On March 2nd, at the Royal Naval Hospital, Plymouth, Benjamin G. Heather, B.N., M.R.C.S., L.R.C.P., aged 30 years.
SCATTERGOOD.—On Feb. 22nd, at Park Square, Leeds, Thomas Scattergood, M.R.C.S., L.S.A., aged 74 years.
WEARING.—On March 2nd, at Mayfield, Victoria Park, Liverpool, Richard Wearing, M.D. Ed., aged 46 years.
WHISTLER.—On Feb. 27th, at 6, Bickenhall Mansions, Gloucester Place, London, William MacNeill Whistler, M.D., late surgeon to the United States Army, U.S.A., aged 63.

THE ANATOMY AND PATHOLOGY OF THE RARER FORMS OF HERNIA (a)

By B. G. A. MOYNIHAN, M.S.LOND.,
F.R.C.S.ENG.,

Assistant-Surgeon, Leeds General Infirmary; Consulting Surgeon,
Skipton and District Hospital.

BILOCULAR HERNIA, INCLUDING INGUINO- PRO-PERITONEAL AND CRURO-PROPERI- TONEAL HERNIA, AND INTERSTITIAL HERNIA.

THE term "pro-peritoneal hernia" is reserved for those cases which fulfil the following conditions:—1. The hernial sac has two loculi. 2. The inner loculus lies between the peritoneum and the fascia transversalis. (Fig. 1.) 3. The outer loculus lies in the inguinal or crural ring, or in rare cases between the layers of the abdominal wall. 4. Both loculi open into the abdomen by a single orifice, the "ostium abdominale." By an interstitial hernia is understood a hernia which fulfils the following conditions:—1. The hernial sac has two loculi. 2. The inner upper loculus lies (a) between the internal and external oblique, or (b) between the external oblique and the skin. 3. The outer lower loculus lies in the inguinal canal. 4. The upper loculus opens into the lower, in some cases close to, in other cases a little distance from, the internal abdominal ring.

All these forms of hernia might, with advantage, be included under the title "bilocular hernia," a name which is appropriate and accurate. The term "bilocular" is applied to a form of hydrocele which is probably very closely related, from the developmental point of view, with these forms of hernia. The apt terms "intraparietal," "interparietal," and "extraparietal" for the sacs within, between and outside the muscles, are employed by Rose and Carless.

In pro-peritoneal hernia the inner sac may have one of three positions:—1. It may pass upwards and outwards from the internal abdominal ring to the anterior superior spine. 2. It may pass directly backwards and occupy the inner part of the iliac fossa near the brim of the pelvis. 3. It may pass downwards and inwards into the true pelvis lying by the side of, or in front of, the bladder. Variety I. has been described as hernia inguinalis intrailiaca, Variety III. as hernia inguinalis antevesicalis (St. Bartholomew's Museum, 2118).

The outer or lower sac may be within the inguinal canal, or have reached the scrotum, or in rare cases may be interstitial. The right side is more commonly affected than the left. In a striking proportion of the recorded cases there has been more or less imperfect descent of the testicle. The history of

some of Breiter and Krönlein's cases show that at birth, or very shortly afterwards, a hernia was noticed, and many of the patients had, for months or years, been accustomed to the wearing of a truss. Most frequently the hernia on examination has been found to be congenital. In fifty-nine cases the sac was congenital in thirty-six: in thirteen no mention was made of this point. In ten only is it definitely asserted that the position of the testis was normal.

ETIOLOGY OF PRO-PERITONEAL HERNIA.

The various theories which have been suggested as explaining the development of these forms of hernia may be tabulated, for the sake of clearness, in the following manner.

A.—1. The scrotal sac is first developed, the interstitial sac being secondary, and arising from the loosening and progressive bulging at the neck of the sac. This may result from cicatricial narrowing of the ostium abdominale, whereby the return of the bowel is impeded (Gosselin; Struebel). "Cicatricial narrowing" of the neck of the sac is freely spoken of in the description of cases and operations. I am disposed to doubt whether it ever occurs, and I am convinced that if it does occur it is only very rarely. Since the introduction of Bassini's, Halsted's and other operations necessitating the opening up of the inguinal canal, the precise conditions existing at the upper part of the intra-canalicular portion of the sac have been more readily and more closely studied. It may, I think, be said that dense induration at the neck of the sac is never observed. 2. Repeated, indiscriminate, and unrestrained taxis on the part of the patient (Streubel). 3. The wearing of inefficient and ill-fitting trusses, which make pressure, not upon the whole canal, but upon the external ring only (Streubel). 4. Irregularity of the developmental process owing to incomplete descent of the testis (retentio iliaca, retentio inguinalis, retentio pubo-scrotalis) whereby the descent of the gut is barred. Impulses from above continuing, the bowel is forced laterally (Streubel; Krönlein). 5. Narrowing of the external ring, while the canal is wide. The bowel readily enough enters the canal, but cannot pass the external ring, and therefore insinuates its way between the layers of the abdominal wall (Mosetig v. Moorhof). 6. Through traction of the omentum when adherent to the neck of the sac (Janzer).

B.—The scrotal sac develops first. Owing to the uncontrolled application of taxis the whole sac is returned between the peritoneum and the fascia transversalis. Later intra-abdominal pressure or other cause leads to the development of a second hernial sac from the parietal peritoneum in the neighbourhood of the internal abdominal ring (Tessier).

C.—The pro-peritoneal sac is first developed as a diverticulum from the parietal peritoneum. A secondary bulging of a part of this sac may extend down the inguinal canal into the scrotum (Linhart; Baer).

D.—The scrotal sac and the pro-peritoneal sac are

(a) Abstract of the First Arris and Gale Lecture, delivered before the Royal College of Surgeons of England.

two originally distinct pouches from the parietal peritoneum. The gradual enlargement of either causes its encroachment upon the other, until the two sacs eventually unite and open into the abdomen by a single orifice (Baer). In this connection it is worthy of remark that in an inaugural dissertation, written in 1883, Wagner relates a case where an ordinary oblique inguinal was found. On the outer side of the hernia, opening into the peritoneal cavity by a separate orifice, was a pro-peritoneal hernia.

E.—The hernia results essentially from an outward dislocation of the internal abdominal ring. As a result of this displacement the cord would be insufficient in length to reach the bottom of the scrotum, retention of the testicle would result and a hernia would be formed in the displaced upper portion of the inguinal process. To account for this dislocation, a "faulty insertion of the inguinal band of the primordial kidney on the abdominal wall" is supposed (M. Schmidt).

F.—The pro-peritoneal sac results from the dilatation of the funicular process between its origin and its entrance into the canal ("first portion" of Eppinger), at which point there is generally a more or less well defined constriction; the interstitial sac results from the dilatation of that part inside the canal (Ramonède).

It is probable that many causes are at work leading to the development of this variety of hernia. There is no doubt that in certain cases, probably the majority, a congenital defect is at the root of the matter. Many years ago Rokitsky pointed out that in the inguinal region, in the immediate neighbourhood of the internal abdominal ring, small pouches or diverticula were not uncommon. These can occasionally be seen even in the adult or in the aged, but I have seen them at their best in the foetus. I find that the most effective method of examination is to lay the subject on the face, remove the sacral, lumbar, and lower dorsal vertebrae, and all the abdominal contents, and expose in this way the anterior abdominal wall from behind. If this be done a fossa or fossæ can be seen clearly defined in at least 20 per cent. of bodies. Moreover, a fossa can occasionally be found (I have seen two striking examples) along the outer side of the hypogastric artery, which in such cases raises up a well-defined fold of peritoneum, a sort of mesentery. It is at least probable that these pouches offer facilities for the involvement of omentum or bowel in them.

With regard to the origin of these small pouches of Rokitsky, it has occurred to me that the explanation given by Lockwood for the origin of the sac of an infantile hernia may be applicable here. As is generally known, this author considers that an aberrant attachment of the gubernaculum is responsible for the abnormal descent of the peritoneum forming the sac. If the gubernaculum can cause the descent of a peritoneal tube into the scrotum, it seems reasonable to suppose that, acting with less completeness, the mere pouching seen in foetuses might very readily result. The area of peritoneum bearing these pouches is precisely that which is in intimate connection with the gubernaculum, and this fact is, to say the least, suggestive.

It may, then, I consider, be taken for granted that the congenital defect leading to the formation of the pouches described by Rokitsky, and possibly also the pouches developed by the side of the obliterated hypogastric, is in some degree responsible for the onset of pro-peritoneal hernia.

A further congenital defect commonly associated, as I have mentioned, with pro-peritoneal hernia is imperfect descent of the testis. This may be the primary defect, and give rise to the development of the necessary sac by acting as a barrier to the further descent of the hernial swelling, or it may be second-

dary and result from the cause, outward dislocation of the internal ring, or another, of the hernia.

The "reduction in mass" of a hernia has been supposed by Tessier and others to be capable of laying the foundation of a pro-peritoneal hernia. Theoretically there is no objection to this suggestion, but practically it lacks sufficient confirmation. I shall presently endeavour to show that it is not unlikely that the condition known as "reduction in mass" is in one of its forms very closely allied to, if not identical with, some forms of pro-peritoneal hernia. The evidence as to the causation of inguino-pro-peritoneal hernia may be thus stated:—

1. The hernia arises most frequently as the result of some congenital abnormality in the inguinal region; as an added factor there may be a loosening, congenital in origin (Linhart), of the peritoneum in this region.

2. In some examples a more or less complete "reduction in mass" may be the original and responsible factor.

3. In a few cases the inner sac may be first fully formed, and the inguinal sac is then a secondary diverticulum; or possibly two sacs originally distinct may, by gradual enlargement and mutual encroachment blend at or near the ostium abdominale.

Cruro-pro-peritoneal hernia may, almost or quite, without exception, be said to be dependent upon the existence of congenital peritoneal pouches. The case of Mr. Knaggs is a most admirable example of this.

ETIOLOGY OF INTERSTITIAL HERNIA.

Much that has been said of pro-peritoneal hernia applies with equal weight to interstitial hernia. The pouches of Rokitsky cannot, of course, stand in any causal relationship. The portion of the funicular process from which the diverticular sac is formed is either the "third portion" of Eppinger or the portion immediately outside the external oblique. Anomalies of the testis are noticed with even greater frequency in interstitial than in pro-peritoneal hernia.

The most satisfactory explanation of the development of interstitial hernia is, I venture to think, founded upon the connection of the hernia with retained testis. The testis bars the way to a further descent of the hernia, and the inguinal portion of the sac bulges out in the direction of least resistance. This explanation is strengthened by the observation, which is almost universal, that the scrotum is hardly ever fully occupied by a sac containing bowel or omentum. As a general rule the lowest point reached by the descending hernia is at or just outside the external abdominal ring. An exquisite example of this is found in the Guy's Museum, No. 1,120. The bulging sac behind the barrier-like testis held "nearly a foot of ileum."

In some cases, however, the testis is normal in position, and the explanation given is therefore inapplicable to them and to the cases occurring in women. There is one explanation, however, which, although I do not think it adequately accounts for these cases, is still deserving of recognition. In the earlier records there is occasional mention of the "thinness" of the abdominal wall in the inguinal region, of "obliteration of the layers," and so forth; but, so far as I am aware, it is to Macready that we owe the assertion of the importance of this condition. He has shown that "the wasting or congenital defect of the muscles is chiefly noticeable below a horizontal line through the anterior superior iliac spine. It concerns sometimes the external oblique as well as the deeper muscles. In a greater or less degree it seems to be a constant feature in the interstitial hernia now under consideration."

I cannot do better than quote the following passage from Macready's "Treatise on Ruptures":—

"If we seek for the principal difference between

interstitial and those herniæ with anomalies of the testis, we find it in the condition of the parietes. I have drawn attention to the delicate membranous state of the abdominal walls about the inguinal region. Here is a difference between interstitial and other herniæ which is common and which is real. If the imperfection of the abdominal wall, so often noticed with these herniæ as existing in greater or less degree, is their original cause, it does not militate against the supposition that a large proportion are attended with anomaly of the testis. On the contrary, when that organ is defective, it is very probable that the parts through which it passes, and with which it is so intimately related, will be likewise deficient, more especially as the anomaly of the testis in these cases is generally of a high grade."

It must, however, not be forgotten that this muscular atrophy and thinning may in some cases be the result rather than the cause of the hernial formation. The weight of a large hernial mass, constantly pressing unduly on the muscular wall, may lead to its wasting or disappearance. Macready does not bring forward any arguments which seem to me convincing in support of his view. I should certainly be disposed to consider the wasting of the muscles which undoubtedly exists rather as an effect than as a cause of the hernia.

In that class of case in which the mural sac lies between the external and internal oblique, if the external muscle be firm and the internal and transverse be thin and atrophied, the resistance met with at the external ring would cause a bulging beneath the aponeurosis of the external oblique. The condition in which the sac lies upon the external oblique may be caused by a testis retained immediately outside the canal, or possibly by the misapplied pressure of a truss, apart altogether from any irregularity, congenital or otherwise, in the muscular layers.

The records of the cases show that in almost all the internal and external rings are opposite one another, forming practically one large opening. The sac can readily enough leave the canal therefore. The obstruction to its downward tendency must then arise external to the ring in one or other of the ways suggested.

A study of the peritoneal conditions existing in pro-peritoneal hernia suggests a close relationship between this form of hernia and the condition described as "bilocular hydrocele." If we suppose that the ostium abdominale becomes closed (by the normal process of "physiological agglutination") and that fluid collects in the inguinal and pro-peritoneal sacs, we should have then a hydrocele of the tunica vaginalis communicating with a serous cavity lying in the abdomen, between the peritoneum and the fascia transversalis. That is precisely the condition found in bilocular hydrocele. A reference to the recent case of Felix von Winiwarter shows that the conditions found in the removal of the sac of this form of hydrocele are the same as in pro-peritoneal hernia, save that in the former the mouth of the sac (ostium abdominale) has closed and fluid has collected in the serous cavity, and in the latter the mouth has remained open and a hernial descent has occurred.

SYMPTOMS AND SIGNS.

Pro-peritoneal Hernia: Inguinal.

With the rarest exceptions cases of pro-peritoneal hernia are first seen when symptoms of acute or sub-acute strangulation are present. A patient who for years has had a hernia, for which perhaps a truss has been worn, begins acutely to suffer from symptoms of obstruction. The hernia may be found on examination by the surgeon, taxis may be applied, and the hernia with little difficulty reduced. Symptoms of

strangulation persist and steadily increase, and operation is resorted to or the patient dies, and the condition is revealed. In some cases—a minority certainly—some swelling may be noticed after the reduction of the hernia. A "sausage-shaped swelling reaching the anterior superior spine" has been more than once reported. But in most cases no swelling is seen, and an examination of the specimens in the London museum explains that. As I have already described, the pro-peritoneal sac may pass outwards, backwards, or inwards and downwards. If outwards, a swelling or an indefinite though appreciable tumefaction may be caused; if backwards, there will be probably no swelling; and if inwards and downwards, there will certainly be none.

Strangulation of the contained omentum or bowel may occur in one of three places:—(1) At the ostium abdominale, the common orifice of the two sacs into the peritoneal cavity. (2) At the neck of the pro-peritoneal sac. (3) At the neck of the inguinal sac. If at 1, the bowel or omentum may be "reduced" from one sac to the other remaining strangled at the ostium abdominale. If at 2, there may be no signs and symptoms but those of acute obstruction, and attention may never be specially called to the inguinal region. If at 3, the case, clinically, is a strangulated bubonocoele or scrotal or femoral hernia. In some few cases, according to Breiter, it has been observed that when two sacs are clearly present, reduction of the hernial content from the outer one causes an immediate and concomitant bulging of the inner sac, and *vice versa*.

The symptoms of strangulation are, one gathers from the record of the case, neither so sudden in onset nor so swift in their increase as in the ordinary strangulated hernia. As a result operation has frequently not been resorted to till the sixth, eighth, or tenth day. In some of the cases I have noticed that "vermicular contraction" of the intestine, "coiling," and "hypertrophy" are mentioned. This would seem to indicate that some obstruction has been of long duration. The sudden stoppage of the intestine by any cause, internal strangulation or strangulation in a hernial sac, never, in my experience, causes any such condition of hypertrophy as is here referred to. A hypertrophied intestine the contraction of which can be seen through the abdominal wall, giving rise to "coiling" and "vermicular contraction," must inevitably be the result of long-standing and either intermittent or incomplete obstruction.

In pro-peritoneal hernia the ostium may be the cause of the partial or temporary obstruction. Almost all the museum specimens that I have examined are to be found, not under the heading "pro-peritoneal hernia," but under "reduction in mass." The symptoms, therefore, are in a large number of cases those of the latter condition. To this point I shall refer again.

So far as the contents of the sacs are concerned there is little to remark. In three-fourths of the cases small intestine alone is present; the omentum, large intestine, and, in one case, the cæcum, have all been noticed. Three of the cases are said to have been examples of what is commonly, though unreasonably, termed "Richter's hernia."

Cruro-pro-peritoneal hernia is much rarer than the former. Breiter records only nine cases, four on the left side, three on the right, and two undetermined. The average age of the patients is higher by several years than that of the inguinal variety. The external swelling is invariably small, and the obstruction has always been furnished by the ostium abdominale.

Diagnosis.

As can readily be understood the diagnosis of pro-peritoneal hernia before operation is sometimes a

matter of difficulty, or even impossible. In cases where a swelling, bulging, or tumefaction is noticed the diagnosis can be, and has been, accurately made. Such cases should offer no difficulty to a careful observer. The frequency of the association of testicular anomalies should make the surgeon prompt to investigate the precise nature of any hernial swelling where the testis is not in its normal position, especially on the right side. If, however, there is no inguinal swelling the symptoms are those of "reduction in mass," of acute obstruction, not as a rule of the most violent type.

Symptoms and Diagnosis of Interstitial Hernia.

In interstitial hernia the mural sac is always capable of being recognised. At one time or another the sac can be seen distended with the usual hernial contents, and no difficulty can be experienced in the recognition. The symptoms are generally inconspicuous and strangulation is infrequent.

Treatment.

Only one treatment can possibly deal effectively with pro-peritoneal and interstitial hernia—operation. The wearing of a truss is useless, and in most cases must also be a source of positive harm. The whole of both sacs should be excised, an undertaking which will involve a certain amount of division or separation of muscular and tendinous fibres. The "radical cure" can be afterwards carried out by any of the methods suited to the occasion,

REDUCTION IN MASS.

I have already remarked that my observations have led me to conclude that many cases of "reduction in mass" are in reality cases of pro-peritoneal hernia. "Reduction in mass" has been described as being the result either of a complete return of the hernia, sac, and contents, undisturbed so far as their mutual relations are concerned, within the abdomen but outside the peritoneum, or of a rupture at the neck of the sac by which the hernial contents escape from the sac into the lax subperitoneal tissue, still strangled at the neck. If the hernia be small and the patient stout the dispersion of the fluid will give an appearance of reduction, whether the fluid has escaped subcutaneously or into the subperitoneal tissue. A rupture of a vaginal hydrocele under pressure applied too vigorously by the patient has been not infrequently recorded.

The impression gathered from museum specimens alone is that the very great majority of examples of "reduction in mass" are in reality no other than cases of pro-peritoneal hernia in which the bowel has been reduced from the one sac to the other. An attempt to gauge the relative frequency of these conditions based upon museum preparations alone is necessarily unsatisfactory. Only the severer cases are there represented. Cases successfully dealt with by operation may be recorded by the surgeon; but his account, however precise, reveals a lack of that intimate acquaintance with circumstances which a careful dissection is alone capable of giving.

Reduction in mass may therefore be described as of the following varieties:—1. Reduction into a sac lying between the peritoneum and the transversalis fascia. This sac has probably received the bowel on many previous occasions. It exists in both the inguinal and femoral regions, forming the special class of hernia known as pro-peritoneal or bilocular. This sac may pass (a) inwards to the bladder, (b) backwards to the iliac fossa, (c) outwards towards the anterior superior spine. This form is probably by far the most frequent. In a very few cases—not five in all—the apparent reduction has occurred into one of the interstitial sacs, beneath or superficial to the external oblique; such a case is that of Mr. Cock (Guy's Museum, No. 1,120).

2. Reduction of the whole sac within the abdomen, but outside the peritoneum, the relations of sac and contents to one another being unaltered, and strangulation at the neck still persisting. It is probable that the loosening of the sac is of long duration, and is the result of vigorous and ill-regulated taxis. This variety is rare. It was first described by Saviard, after Le Dran, Lafaye, and Richter.

3. Rupture of the neck of the sac, and escape of the contents of the sac through the rupture into a cellular space outside the peritoneum. The rupture generally occurs at the back of the sac just below the neck. This form of reduction has been well described by Birkett. If fluid alone escapes while the bowel remains, an illusory appearance of reduction will be presented. It might be worth while to emphasise this condition as "false reduction in mass," for clinically the two conditions of "false" and "true" reduction may be precisely similar. If in "false" reduction the rupture is at the distal extremity of the sac and the discharge of fluid subcutaneous, it is impossible, of course, for bowel to escape.

As a variety of this form may be mentioned the passage of the strangled intestine through a cut made near the neck of the sac when a hernia knife has been introduced to divide the "stricture at the neck of the sac." Madyl has observed this accident. After the supposed division of the strangling band pressure is applied to the bowel, and reduction apparently occurs. The neck of the sac is however untouched, and the strangulation consequently persists. A very beautiful example of this kind is recorded by Farabœuf. This form also is rare.

A fourth form of "reduction in mass" is described and figured by Roser, and mentioned by Pick. It consists in the reduction "into the inguinal canal" of the bowel that has formerly occupied the scrotum. A wide dilatation of the canal is considered as permitting this partial reposition. I have not been able to discover a museum specimen of such a condition, nor have I found any unequivocal case in the literature of this subject, though mention of the condition is made by several of the earlier writers on hernia. Chelius considered that in herniæ of moderate or large size, when reduction was apparently complete, a small segment of gut, thick with inflammatory products and paretic, might lie inert in the canal, and undergo a later secondary strangulation.

Reduction of the strangulated contents of a hernial sac into a second underlying sac in the scrotum have been recorded by Armand, Horn, Sandyfort, and Scarpa. It is possible that these second sacs are pulled down into the scrotum by gubernacular bands in the same manner as the sac of an infantile hernia. Demmeaux has suggested that whether the sac first present in the scrotum be congenital or acquired, the press of intestine on a weak and loosely supported neck may cause a diverticulum slowly to develop. Such pouch may be in front or behind, to the inner or outer side.

If rupture of the neck of a femoral sac occurs the bowel may pass into the sub-peritoneal tissue. Callisen recorded in 1777 a case where, owing to rupture of the sac below the neck, the bowel had escaped and made for itself a lodgment between the pectineus and psoas muscles.

These conditions may be represented in tabular form thus:—

REDUCTION IN MASS.

<i>True.</i>	<i>False.</i>
1. Reduction into a pro-peritoneal sac; rarely an interstitial sac.	1. Rupture of the sac at the neck or elsewhere, with escape of fluid only.
2. Reduction of the	The hernial swelling be-

True.

whole sac, with contents, within the abdomen, outside the peritoneum, the mutual relations of sac and contents being undisturbed.

3. Rupture of the neck of the sac or its division during operation and extravasation of the hernial contents into the sub-peritoneal tissue.

False.

comes considerably smaller, but the bowel remains strangled.

2. Reduction of part of the hernial contents. A small portion remaining in the canal, paralysed and stiff with inflammatory products, undergoes a "secondary" strangulation.

The Jettsonian Lectures.

PRACTICAL OBSERVATIONS

ON

CANCER OF THE BREAST. (a)

By SIR WILLIAM M. BANKS, LL.D., F.R.C.S.

Surgeon to the Liverpool Royal Infirmary; Emeritus Professor of Anatomy in University College, Liverpool.

LECTURE I.—(Concluded).

THE PARAMOUNT IMPORTANCE OF EARLY DIAGNOSIS.

As one goes on seeing case after case with gentlemen in general practice, one gets to find out that, even with the highest standard of modern education, a great many errors are still being committed by doctors in the matter of the early diagnosis of mammary cancer. Now, seeing that in the matter of its cure we have nothing but free removal to fall back upon, the smaller the amount of disease the better the chance of cure. Early diagnosis is, therefore, of paramount importance. If this can only be steadily crammed into the minds of students and practitioners, a remarkable increase in the number of permanently successful operations will ere long result. This is the real line of improvement at the present moment, not in devising extravagant operations for cases that are past praying for. It is true that in the very early stages of a mammary cancer, a certain and positive diagnosis cannot be made, even by the most skilled and experienced surgeon. Nobody, therefore, expects that of the general practitioner. But I have found that, when the patient comes and shows her doctor a small lump in the breast, if it does not seem anything very formidable, he is unwilling to frighten her, talks vaguely about a "swollen gland," and generally is apt rather to make light of the matter. There is a phrase I know well which must have cost a great many people their lives, "If it doesn't bother you don't bother it." It is a most destructive axiom. Then the patient goes home, the lump grows and she sees it growing, but she buries her head in the sand and repeats to herself that the doctor didn't attach any importance to it, and so nothing can be going wrong. In due time she becomes terrified and repairs to the doctor. There is a distressing scene, and then they repair together to the surgeon, who says he thinks he can get the disease out, but is not sure. Now what I would implore my brethren in general practice to do is to cease regarding any lump in the breast, however small, as harmless or unworthy of the utmost attention. No man can tell what is going to become of a small lump in the breast. All strangulated herniæ are now operated upon without delay if they will not go back—so all lumps in the breast ought to be cut out, if they will not speedily disappear.

(a) Delivered before the Medical Society of London, Monday, March 5th, 1900.

As to frightening the patient there is no necessity for unnecessarily alarming her, but, even if it were so, how much better that she should get a needless fright in the beginning, than be ultimately terrified by the dreadful intimation that her doom is sealed, and that a brief period of agony is all of life that is left to her. My advice to a general practitioner would be that, when a patient comes to him with the smallest lump in the breast, he should at once send her to a surgeon. If she be a poor person he will assuredly have a surgical friend who will see her gratuitously for him. Were I a younger man I dare not say this. If an absolutely certain diagnosis cannot be made on the moment, the point is to get the patient to visit the doctor month by month to let him see what is happening to the lump. It seems hardly credible, but on several occasions I have seen a patient in consultation with her own medical man about an early mammary swelling. It has been impossible just then to give a certain opinion about it, treatment has been suggested, and a strong recommendation made that the swelling should be carefully watched. And yet, after a year or more has elapsed, they have so muddled up matters between them that the patient has been brought back with a pronounced cancer. This is a statement of fact, and not an ideal picture. We have just been considering various conditions relating to cancer, upon which have been brought to bear ingenious speculations, supported by statistical researches involving years and years of labour. All these researches are not of the faintest moment (considering the nature of the solitary method of treating cancer of the breast which we possess) compared with the value of early recognition of the disease. Every effort should be made by teachers to inculcate the doctrine of early recognition upon students for, if there is a hopeful day to come for the sufferers from cancer of the breast it will be when women have been taught by the medical profession to present themselves on the slightest symptom of anything being found wrong with the mammary gland. Too often at present they hug their distressing secret and only part with it when it cannot be concealed, and small wonder it is when one reflects that the present generation are still under the influence of the depressing tales told them by their mothers about the horrors of cancers of the breast, and the terrible and useless operations performed for its relief. I hope my medical brethren will forgive my speaking in this very forcible manner about what appears to be a very simple thing. It is a very simple thing, but, simple as it is, it is the real secret of the future of the operative surgery of cancer, and we are not getting what we ought out of it. Let me not be supposed to reproach my profession with ignorance (for I trust I can recognise the many mistakes I have made myself), but to expect omniscience from the general practitioner is absurd. I consider that the range and extent of his knowledge is astonishing, but the early diagnosis of many mammary enlargements will defy the most experienced touch. It is only by early co-operation between the medical attendant and the surgeon that the patient's chances can be saved to her.

CONSTITUTION AND HEREDITY.

One of the terrible mistakes of former days, which gave cancer the character of being even more hopeless than it is, was the idea that it was purely a constitutional disease. To remove it in one place was useless, for it would just break out in another. Now the modern scientific inquirer, whose first consideration is too often to sweep contemptuously aside all that his predecessors have excogitated, asserts that there is nothing constitutional whatever about cancer, that it is a purely local disease and that it is certainly an infective one. It seems odd why there should be

any difficulty about the question. It is a long time since Laycock first described the diathetic tendencies of the body and how they influenced all the illnesses which attacked that body on its way through life and often so modified them that they were almost unrecognisable, so changed were they from their usual types. Paget used to draw our attention very vividly to the remarkable way in which the gouty diathesis affected surgical disease. We know, nevertheless, that it does not necessarily follow that, because a man has a diathetic tendency, it need ever become obviously manifest. He may go through a long life and never show it until some *contretemps* brings it to the surface. An old friend of mine, whose male relatives to a man were all full of gout, lived to over 70 without a trace of it. He drank champagne and port most days, but he was small and thin and a passionate sportsman, so that he staved off the gout by great physical exercise. But at last one day he fell off his shooting pony and hurt his ribs. While lying in bed recovering from the injury he had a serious attack of gout in the foot. For the next two or three years of his life it never left him, and it killed him with acute cerebral trouble at the last. If in place of "gout" we were to put "cancer" into this little case there would be really no difference. But that cancer should in some way be set agoing in a particular spot of a perfectly healthy man's body by the process of infection and should then produce a constitutional state—apart from mere spreading by lymphatic channels—is with our present knowledge difficult to realise. If you were to take a fine, wholesome, clean-blooded man, the descendant of a race who had for generations been free from all morbid diathesis, and put tubercle into him you could not make it spread. It would die out locally. It requires a distempered constitution, like a sour, impoverished soil, gives the appropriate pabulum for pathological weeds, which seed and spread through it and ruin it. We know now how the tubercle gets sown. The cancer weed may yet be caught and bottled too. When we think what an absolute revolution has taken place in our views about tuberculous disease, we must not despair about cancer. It is a curious thing, however, to remember that while the North Italian peasants regarded phthisis with the greatest dread as an infectious disease, scientific medical men were the very persons who scouted the idea. Long continued experiences are worth something after all.

As to heredity, it behoves us to be very careful how much importance we are to give to this in a difficult case of diagnosis of a breast tumour, where side issues have to be taken into account. By the public, without doubt, too much value has been always attached to it. The patient consoles herself with the belief that hers cannot be a cancerous tumour because nobody in the family was ever known to have such a thing. Unfortunately, we can only put the matter in this way; while the want of history of a cancerous tendency inherited from her progenitors is no proof that the patient's disease is not cancer, the existence of it among several near relations is distinct evidence in the direction that it is so. There have been attempts made on certain abstruse developmental grounds, to overthrow the possibility of the heritability of acquired (diseased) variations, notably by the philosophic teaching of Weissmann, but nothing has come of them. A great deal of philosophic froth has been beaten up, and much learned verbiage has been poured about, but I have never seen abstract philosophy do much in disease. Our knowledge—our most useful knowledge—has been gained empirically. And so patient collectors of facts have told appalling histories of whole families who have died from cancer, and have disseminated it among their descendants, which are now so numerous

and well authenticated as to leave no doubt in the mind of any surgeon (not a philosopher) as to the existence of heredity, and what we have to do is to attach to it its appropriate value clinically, and by no means to consider that the absence of heredity is proof of non-malignancy in a tumour. It is true that as a general rule cancer in a family seems very erratic in its visitations, and appears to jump over a generation, but we may take a simple view of the question thus as explaining these irregularities. What figures seem to show is that the inherited infectivity of cancer is not strong and dies out most likely at the end of a couple of generations. In the midst of a family among whom cancer was never known a healthy man develops (catches?) cancer, and throws the gloomy pall of hereditary diathesis over his children and grandchildren. A son shows it, but his children escape, while a niece—the originator's grandchild—shows it. The rest escape because the match has not been applied to the tinder, just like my friend who escaped hereditary gout till he met with an accident towards the end of a long life, which set it ablaze in him. It is impossible to resist coming again and again to ask "What is the match?" Meantime, until a very clear answer is given to this, I see no occasion for throwing overboard what knowledge we already possess.

Dr. Boswell Park in his chapter on the "Frequency and Nature of Cancer" in the *Practitioner*, already alluded to, writes as follows: "Next with regard to the actual nature of this disease. First of all, it is possible to sweep aside, with one or two possible exceptions, everything that has been brought forward until recent years as an explanation of this disease. The old theories of irritation, of perverted nerve centres, of heredity, &c., cannot for a moment stand in view of the searching scientific methods of to-day. We have gotten as far as this at present that we know that cells act as they do in producing the disease either as the result of some external or of some internal stimulus. The exact character of this stimulus is not yet certainly demonstrated, though things point more and more towards its parasitic, i.e., its potent living influence." To the first part of this statement I entirely demur, because I am so old-fashioned as not to have got far enough to sweep aside all that experience has accumulated until I have something to put in its place. With regard to the second part it seems to involve on the part of Dr. Park what an old Scotch judge called "A plain perception of the obvious." What we all want to know is, "What is the match?" and there is no certain answer to that as yet.

Traumatism.—We are all very prone to produce some distinct reason why a disease should have come to us. That it should come spontaneously is a stigma upon the soundness of the constitution, and so we wish to find out a cause. But the natural liveliness of the female imagination makes it difficult to apportion with anything like accuracy the exact amount of credence to be placed in their statements. I must say that I have never been able to make out that milk abscess or the scars of incisions for them have ever been the starting points of cancer, and, curiously enough, although the patients have mentioned the existence of these things, I do not remember having heard them distinctly and directly attribute their growths to them. After all, if cancer ever develops in inflammatory products it is in those of a very chronic and not of an acute nature. I never heard, furthermore, any statements from the patients that pressure from corsets or that irritation of the nipple by suckling had produced their complaints. On the other hand, I have very often heard most clear and circumstantial histories narrated in which blows were asserted to have been the primal cause of the trouble. It has

been held as an argument against the effect of traumatism that men are very much more liable to blows on the breast than women, and most rarely have breast cancer. I very much doubt this. Take a number of men at fifty and an equal number of matronly, full-bosomed women of the same age, and it stands to reason that the latter will get more knocks on the mammae than the man. Moreover, they are always in the way of getting knocks from young children or from articles of furniture, such as cribs and bedposts, among which they are always working. Besides what is a man's breast after all? A little mass of fibrous tissue with some rudimentary gland stuff in it, whose small size would save it from many blows which a big, soft, vascular female breast must encounter. Moreover, it is contended that, if blows caused mammary cancer, the lesions would be multiple, but this shows how things appear differently to different people, for I do not suppose that if a woman gets an injury to her breast she gets it in the form of a series of thumps all round so as to produce multiple cancers. I have received very succinct accounts from intelligent women of blows from pieces of furniture or kicks from young children in which there was pain immediately afterwards sufficiently severe to fix the exact place in the breast in the memory. Then the pain has gone away, they have almost forgotten the circumstance until some day a lump is found at the old site of injury. Were the allegation true that the injury directs the woman's attention to a tumour which is lying concealed in her breast already, then she would discover it at once on receipt of the injury, but this is not the history of these cases. The history is that of an interval after which the lump comes painlessly. Many of the patients whose histories I have ascertained were far too intelligent to have invented the story after finding the lump. Mr. Roger Williams says that in examining the cases of 137 women, one out of four made statements as to previous traumata. I should hardly have thought so many would have done so, for, supposing we put one-half of them out of count at once as imaginary, it would leave one case in eight in which there was not improbably some truth in the patient's statement. After the way in which the vulgar but rooted belief in the infectiousness of phthisis of the Italian peasant has, in the light of modern discovery, triumphed over the contemptuous disbelief of the whole world of medicine I am not disposed to abandon all belief in the statements of women whom we will even admit to be anxious to find a cause for their malady. Constant repetition from different sources strengthens even a weak tale provided the evidence be steadily in the same direction. I have investigated these stories too often not to feel that, stripped of all exaggeration, there is a distinct element of truth in them. Remember, I do not make any attempt to assert that cancers of traumatic origin are at all frequent, but I believe in the possibility and, indeed, in the strong probability of their occurrence. I cannot see anything irreconcilable with our pathological knowledge in the idea of a blow, leaving behind it a certain limited area of chronic inflammation in which the gland epithelium should begin to grow and then burst its bounds, just as I am certain it does in chronic mastitis. Dr. Boswell Park says: "The supposed intimate relation which injury bears to cancer is of no more importance than that upon which the clinicians, and even the pathologists used to place so much stress in tuberculosis. There are still those who claim that the predisposing cause of most tuberculous joint diseases is previous injury of some character, and there are still those who look for a similar mechanical cause of cancer in virtually every case." I am not one of those who look for a

mechanical cause of cancer in virtually every case, but I venture to say that there is no practising surgeon in this country who has had much to do with joint disease who does not recognise the immense importance of wrenches, blows, and sprains in the production of the early inflammatory changes in and about joints which ultimately end in what is known as articular tuberculous disease. I was educated in exactly the opposite view, viz., that the tales which mothers told about injuries to their children's joints were all nonsense, and I was forced out of this belief by the irresistible arguments of experience.

One feels the more inclined to this view from the knowledge that acute traumatic malignancy is a well-recognised disease. Scattered throughout the medical journals are so many cases of its occurrence that no possible doubt can be entertained about its existence. In the *British Medical Journal* for 1882 are two short but very interesting papers on the subject by Messrs. Barwell and Harrison Cripps; also a third by my friend, Mr. Puzey, of Liverpool, detailing in a most interesting manner the history of a man who was struck over the sternum and in whom there was developed at the spot a sarcoma. It is true that in all the cases I have read sarcomata and not carcinomata supervened, and therefore the disease is rightly named "acute." But if injury will, so to speak, on the spot start into existence the swift growing tumour of the connective tissue, why should it not at a longer interval give rise to the slow growing tumour of glandular lining epithelium?

THE DILATATIONS AND DIVERTICULA OF THE ÆSOPHAGUS.

By JOHN KNOTT, M.A., M.D., CH B., and Dip.
Stat. Med. (Univ. Dub.); M.R.C.P.I.; M.R.I.A.; &c.

(Concluded.)

IN proceeding to notice the third or *hernial* class of œsophageal diverticula in Rokitansky's arrangement, I must take special notice of the radical views so emphatically advanced by Zenker (*Ziemssen's "Cyclopedia,"* Vol. VIII):—

"A number of the modern writers distinguish two different kinds of sac-like diverticula, which, resembling each other in their location, shape, &c., are distinguished from one another by the presence or absence of a muscular layer in their wall. They according assert that they arise in different ways, and consider those that have a muscular layer as congenital formations. But having carefully studied the literature of the subject, and having ourselves investigated four of these very preparations, we consider that this distinction has no adequate basis, but do believe that all diverticula occurring at this place must be considered as identical in anatomy and pathogenesis. Without doubt the reports of many cases by observers do assert the presence of a muscular layer in more or less precise terms. These doubts arise not only from the opposite statement of those observers who are the most reliable (Chas. Bell, Rokitansky, Ogle), and the results of our own examination of these preparations in the Museum of Pathological Anatomy at Erlangen (of which one is the most beautiful specimen of its kind), from which we find that in all these cases (except in a portion of the neck of the largest one) there is no muscular layer whatever; but above all, from the statements, partly indefinite and partly incredible, concerning the arrangement of the muscular fibres in the wall of the sac; and finally, from the result of our own examination of one of these cases, in

which the existence of a muscular layer is asserted in the most plain terms. It is that case, so interesting in every respect, reported by Fridberg (observed by Dr. Gassner in Mainz) in his careful dissertation, of which the preparation is to be found in the Museum of Pathological Anatomy at Giessen. In speaking of the large, flask-shaped diverticulum, three and a half inches long, hanging down the œsophagus, Fridberg says it is made up of 'all the layers of the œsophagus, the muscular layer is moderately developed, and the fibres run in a regular manner entirely around the sac.' Although this statement leaves nothing to be wished for in precision, yet I could not repress my doubts of its accuracy, and so had recourse to Professor Perls, with a request that I might prove this point, and he had the kindness to send me the specimen for my own examination. My examination showed, in fact, that Fridberg's statement concerning the muscular layer was totally incorrect. The mucous membrane, as in the other cases, was found to bulge outwards between the lowest separated fibres of the inferior constrictor muscle. Two of the separated fibres reached down to some extent upon the neck of the diverticulum. On all the rest of the sac not a muscular fibre can be found. Accordingly, Fridberg's argument concerning the pathogenesis, which rests upon the presence of the muscular layer, naturally falls to the ground, and the simple and natural explanation, which he opposes, is re-established. From what has been said, it is evident that this diverticulum also arises from the pharynx, and not the œsophagus, as Fridberg states.

"After this result we shall not be blamed if we believe that the few remaining cases in which a muscular layer was declared to be present are equally incapable of demonstration, as, e.g., the case pictured by Albers (Atlas, Part II., Plate xxxiii., Figs. 1 and 2), in which a 'thick layer of muscular tissue' was said to exist; but certainly it would not be suspected on examining the plate. In his interesting case, so often quoted, Kühne only says in general that the outer layer 'is made up of muscular fibres of considerable thickness coming from the œsophagus, which spread out like a web over the surface of the sac,' which certainly cannot be interpreted as meaning a continuous muscular layer. And in Worthington's case, in which 'nearly two-thirds of the sac is covered with muscular fibres from the constrictor of the pharynx,' at least a considerable portion of the sac, according to this statement, must have been free from such fibres; other cases are less capable of proof on account of even less complete statements.

"But the assumption that the muscular layer, when wanting, may have formerly been there, but has become atrophied by the enlargement of the sac (Klebs, Koenig), is not only entirely gratuitous—for the statement by Klebs, in opposition to our experience, that most of the smaller sacs present all the coats, finds no proof in the literature of the subject—but also, for the cases which we have investigated, would be entirely untenable when we consider the arrangement and origin of the fibres of the inferior constrictor through which the mucous coat protrudes."

Notwithstanding the fact that the writer of the above paragraphs has evidently given the most careful—even enthusiastic—attention to this seldom-studied section of pathology, I cannot help expressing the opinion that his view is too exclusive. The fact of the absence or wide dispersion of the muscular fibres in the wall of a sac of long standing, when even of but moderate size, is no proof that they did not exist at the time of the original expansion. And I will even go so far as to hold it to be a physical impossibility for a local bulging of the mucous membrane of the normal œsophageal—or pharyngo-œsophageal—

wall to take place without carrying muscular fibres in its circumference. The only cases in which such an accident could possibly occur would be those in which there exists a local deficiency in the muscular fibres, which would mean a congenital predisposition—if not an actual congenital preformation—to the reality of which Zenker so very strongly objects. There is one other point which, in my opinion, strongly militates against the exclusive view taken by Zenker. Referring to the frequency of regurgitation of food, he observes that, "The ingesta which have fallen into the diverticulum may remain there one or many hours (perhaps even for days—case of Collomb), when apparently involuntarily in part (probably by compression of the sac laterally by the contraction of the muscles of the neck), and partly by pressure with the hand upon the neck, they are again brought up into the mouth, sometimes entirely unchanged and sometimes only softened and mixed with mucus. Then they are either ejected from the mouth, or the patient attempts to swallow them again, so that in many cases there is actual rumination. This symptom is most characteristic, although, as we saw, it occurs also in diffuse dilatation." [The italics are mine.] The views of an enthusiast, if not gifted with an exceptional quantity of mental ballast, are very likely to run into a one-sided advocacy; and venture to express the opinion that the above quotation offers an example of this rule. The "probably" begs the question of the source of the pressure exerted upon the contents of the sac; and I believe that all discriminating readers will agree with me that it is most unlikely that a special form of contraction of the muscles would be unaccountably brought into play at such long and irregular intervals in a case where there existed a continuous source of uneasiness. The influence of the pressure of the hand upon the neck is, of course, unmistakable; but it is unlikely to be employed till the sac has attained so considerable a size as to form an evident local bulging. When it does the discomfort caused by its pressure is sure to lead to manipulation, which is also sure to be repeated after each meal; or, as in some cases, after each act of deglutition. The result, simply or in combination, of these two factors of compression would not, I submit, give the regularly-recurring habit of rumination which existed in some of the recorded cases; and still hold that the "apparently-involuntarily-in-part" regurgitations, of which the existence is unquestionable, can only have been due to the action of the muscular fibres in the wall of the diverticulum itself.

Zenker also expresses the opinion that the lodgment of a foreign body is "perhaps the most frequent method of their origin." The most remarkable case on record of such (apparent) origin is, so far as I know, that of Ludlow, which I have already dealt with at length. Other cases referred to by Zenker are those of Dendy, in which an eight-day lodgment of a peppercorn formed the first item in the history; of Kühne, in which the corresponding agent was a chicken-bone; of Klose and Paul, in which the corresponding offender was a fish-bone.

An extremely interesting and suggestive case bearing upon this method of causation has been recorded by Mondière (Arch. Gen. de Méd., 1890). I must mention that he accepts Ludlow's view of the *modus operandi* of the foreign body in the case above quoted; and, of course, in other corresponding cases. He then proceeds, with evident intellectual unction, to give the history of a case: "*dans lequel la nature fut pour ainsi dire prise sur le fait*":—

A peasant, æt. 20, of robust constitution, swallowed during sleep a stone with which he had been amusing himself for some little time before by rolling it in his mouth. After awaking he felt severe pain in the

chest, together with complete inability to swallow. The symptoms progressed with increasing severity, and he died nine days after the occurrence of the accident, and, on examination of the body, the œsophagus, stomach, and parts of the intestines, were found in a state of gangrene. The stone, "*était en quelque sorte chatonnée*," in the lower part of the œsophagus, where it had formed a sac on the right side; this sac was corroded by the suppuration, so that a portion of the stone lay bare in the cavity of the thorax, beside the trachea.

Now, the above case, although brought forward with very evident eagerness by the distinguished French pathologist, as the brightest available illustration of the mode of formation of sacculated diverticula of the œsophagus, does not, in the opinion of the present writer, by any means lend—even a shadow of—support to his view of their development. I can quite understand the pressure of so hard and irritating a body on the walls of the gullet leading to violent inflammation, ending in sloughing and perforation, with supervention of complications necessarily ending in a fatal issue. But with regard to the formation of diverticula, I have no hesitation in asserting that the above case, if it proves anything, proves that such a foreign body could not lead to the formation of a sac, as the want of adaptability of the œsophageal wall in that instance was absolutely demonstrated. And if that stone had met with a (congenitally) weak yielding spot in the wall of the tube, it is just possible that its pressure might have led to the gradual development of a sac of some size. But it is only in the case where the pre-existence of, at least, a slight bulging could have afforded accommodation to the obtrusive foreign body—and without complete interruption of the act of swallowing—that the presence of such an agent could possibly have led to the result in question. The tolerance of a sac, when fully developed, for the presence of foreign bodies was shown in Förster's case, in which several pieces of buck-shot were found in the fundus, which had become smooth by mutual attrition, and in Zenker's own case, in which he found a little piece of slate "somewhat larger than a kreuzer." In the Veit-Berg case, a piece of coarse corn was present; and in the famous case of Ludlow, to which I have so often referred, the sac contained a large quantity of quicksilver which the patient had been made to swallow fourteen days before his death.

As illustrations of the other forms of mechanical injury which may lead to the formation of a pouch in the gullet or its vicinity, I may again refer to Gasner's case (reported by Fridberg), in which the accident to which a pharyngeal diverticulum could undoubtedly be traced was a fall from a horse; to Waldenburg's case, in which the origin was referred to a quarrel in which the patient, a female, was throttled by her opponent; and to the cases mentioned by Kühne and Buckling in which the primary cause was believed to be the pressure of tight clothing around the neck. These cases were, however, all pharyngeal.

Zenker, who is so emphatically sceptical with regard to the congenital origin of the majority of these pouches, refers to eight cases in which the symptoms commenced after the age of forty. He is disposed to regard ossification of the cricoid cartilage as the principal factor in such instances; the normal resistance thus developed in front throwing so much pressure on the posterior wall of the tube. Sir Charles Bell referred the origin of some of the pouches which form at the junction of the pharynx and œsophagus to the obstruction produced by spasmodic contraction of the upper part of the muscular wall of the latter; the same idea was also entertained by Monro. But although recurrent spasm in this position—so-called *œsophagismus*—is a well-

known source of trouble, especially in female patients of "neurotic" temperament, it is more than doubtful whether such functional derangement is ever, of itself, the cause of so pronounced organic change.

Local paralysis of the muscular walls of the tube is a recognisable cause which may lead to the formation of a diverticulum. The same may be said of ulceration, either simple or specific, which, by weakening of the parietes at any point, would necessitate their yielding to the pressure of the ingesta during deglutition. I have myself under observation at present a case in which I believe that a small diverticulum has formed; and from a cause which I do not recollect to have found recorded or suggested elsewhere. A lady, whom I treated for œsophagismus some eight years ago, went to reside in a London suburb, where the trouble required frequent use of the œsophageal bougie. On coming to Dublin a few weeks ago she consulted me again about her dysphagia, which I naturally thought would turn out as before to be of nervous origin. The hitching of the bougie on some occasions, with its free passage at other times, leaves no doubt on my mind that a pouch has developed. She states that her London practitioner had often to use a good deal of force to pass the instrument.

The existence and genesis of "traction-diverticula" of the œsophageal wall has been made the subject of very careful study by Zenker. The first description of this peculiar lesion was furnished by Rokitanaky. His original account was based on a single case. This appeared in 1840; but, till the publication of Zenker's observations, the subject does not appear to have received much attention.

"The starting-point is an inflammatory swelling of the parts immediately adjoining the œsophagus, which leads to a firm adhesion between this inflamed region and a limited portion of the wall of the œsophagus. If cicatricial induration and contraction follow in these inflamed regions, since they are also adherent to less yielding structures (particularly the wall of a bronchus), they must draw that portion of the œsophageal wall outward. This method of origin in the great portion of cases is so evident from the anatomical appearances that in the presence of such preparations there can be no dispute about it. Experience tells us that it is disease of the tracheal and bronchial glands, especially those at the bifurcation, which is the most frequent cause of such inflammation; and it is the dense accumulation of these glands at the bifurcation which makes the corresponding portion of the œsophagus the seat of election for the formation of these diverticula." The remote cause of the condition is, in the majority of cases, not discoverable. Zenker looks upon tuberculosis and chalicosis as the most frequent sources.

This distinguished pathologist had seen and investigated more than sixty such cases at the time of the publication of his observations in Ziemssen's "Encyclopædia." He has there given sufficient evidence of the great danger of the existence of these—usually unsuspected—pouches. "Their shape, with rare exceptions, is that of a narrow or somewhat wider funnel of only moderate depth. Most frequently we found them from two to eight millimetres deep; yet in a few cases they attain a depth of nine to twelve millimetres. Larger diverticula than this certainly are very rare exceptions." In many of these cases the mucous coat alone forms the sac—protruding between the muscular layers. When a foreign body happens to lodge in one of these little sacs, or some source of irritation leads to inflammation, there is great danger of perforation, which is extremely likely to lead to a fatal issue. The opening is often into a bronchus; it may also be into a pleural cavity or into the pericardium. Cases of perforation of the aorta and of the pulmo-

nary artery have also been observed—followed, of course, by immediate death.

Down to the happy era of the researches and results of Lister and of Pasteur, the condition of oesophageal dilatation was one of the most distressingly hopeless of the ills to which suffering humanity is heir. The colossal strides made by advancing surgery since the perfecting of its aseptic methods have, however, achieved successes even in this, which had previously been one of the most unmanageable of all human ailment. Von Bergmann, after extirpation of the diverticulum, did not attempt to secure healing by first intention. Billroth left in an oesophageal tube through which he fed the patient for some days. Kocher preferred rectal alimentation to using any means that might cause disturbance of the process of union in the wall of the gullet. But Dr. C. Hoffmann has recently recommended a more rational line of procedure than any of these. In the *Deutsch. Med. Woch.*, August 3, 1899, he urges the advantages of his method, of which he reports two successful cases: Gastrostomy should be performed some time before excision of the oesophageal sac is attempted, because (1) the patient can be fed up into good condition so as to enable him to bear the second operation with better hope of success; (2) the oesophagus obtains rest, and any inflammation existing in the wall of the sac has time to subside; (3) the sac, if large, can be washed out, and all traces of decomposing food removed. The second and third of these are very important items, aiding primary reunion of the oesophageal wall after operation. I look upon this as the most scientific and the most hopeful method of procedure in dealing with all *Dilatations and Diverticula of the Oesophagus*. I look upon this as the most hopeful method of procedure in dealing with all *Dilatations and Diverticula of the Oesophagus*.

Clinical Records.

OVARIAN TUMOUR OF AN UNUSUAL CHARACTER. (a)

Under the care of Dr. T. JASON WOOD.

The patient was a married woman, æt. 48, admitted July 29th, 1891, to hospital with a six months' history of abdominal pain and swelling. The pain had become worse since May. On admission, patient, looking very ill, was pale and emaciated, complained much of pain and nausea, has vomited once. The abdomen is uniformly distended by a tense cyst, which reaches 2 ins. above the umbilicus. There is much tenderness on pressure. Flanks resonant to percussion. On vaginal examination the uterus was found to be high up and fixed. Temperature 100.5 degs., pulse 114.

On August 4th, patient under ether, the abdomen was opened below the umbilicus. The peritoneum was greatly thickened, and the cyst universally adherent. It was found to be multilocular in character, and some of the loculi contained fetid green pus. During separation of the cyst the wall gave way in places, and allowed some of the pus to escape into the peritoneal cavity. When all the adhesions had been separated, it was found to be possible to remove the cyst, there being no trace of a pedicle. The small intestines were confined to the upper part of the abdomen by adhesions, so that the cavity occupied by the tumour remained. It was washed out with hot water and loosely packed with alembroth gauze. The end of the gauze was brought out of the wound, which was closed, and a cotton-wool dressing applied. The ovaries could not be recognised owing to the great inflammatory thickening of the peritoneum. The gauze was removed after forty-eight hours, and a tube substituted. The patient made a good recovery. Discharged September 16th. On examination of the

cyst, such of the loculi that did not contain pus contained a clear straw-coloured fluid. Microscopic examination showed the wall to be composed of fibrous material lined with cubical epithelium. The cells were rather smaller than are usually seen in multilocular cystomata.

Dr. Wood suggested that the absence of a pedicle was to be accounted for by the ovary becoming detached from its usual connections, and then undergoing cystic change.

Transactions of Societies.

CLINICAL SOCIETY OF LONDON.

MEETING HELD FRIDAY, MARCH 9TH, 1900.

SIR R. DOUGLAS POWELL, Bart., President, in the Chair

DR. RICHARD CATON on the

PREVENTION OF VALVULAR DISEASE IN ACUTE RHEUMATISM.

Feeling strongly the great importance of the sequelæ which frequently follow valvulitis in attacks of acute rheumatism, the author began nineteen years ago to try various measures of prevention. Fifteen years since he decided upon a definite method, which has been followed ever since. The clinical material to which this method has been applied consisted in nearly five hundred cases of acute rheumatism. These were treated in the ordinary manner by salicylates, cholagogues, and a light diet, the whole body excepting the head was clothed in flannel, and the patient kept in bed for some weeks; any lingering pains were dissipated by small blisters locally. The proportion of cases of valvulitis was under 20 per cent. The following signs were considered to indicate affection of the valve; *assourdissement*, going on to the development of a bruit, usually mitral, mostly systolic, but sometimes presystolic, heard in the axilla, followed by accentuation of the second pulmonary sound; more rarely a diastolic bruit at the aortic cartilage. Treatment consisted in the three following measures:—(1) Absolute rest in bed for several weeks. (2) The application of a series of blisters, in size somewhat less than a florin, one at a time, in the course of the 1st, 2nd, 3rd, and 4th dorsal nerves; after each blister a small poultice is applied. (3) Sodium or potassium iodide in eight or ten grain dose is given thrice daily; in some cases small doses of mercury. The object of the rest in bed is of course to protect as far as possible the softened and weakened valve cusps from pressure. The object of the blisters is to stimulate the trophic nerves of the heart through the sensory filaments of its related skin area, and so as to hasten repair and absorption, just as the reparative process in a joint is unquestionably stimulated by blistering the adjacent skin. The purpose of the iodides or mercury is to help absorption of the, at first, imperfectly organised inflammatory products in the cusps and endocardium. The author believes this treatment only to be of use if commenced early, say within the first two or three weeks. In long-standing cases it is absolutely useless. Carefully setting aside all cases of slight transitory bruit, all cases of hæmic origin and all that seem due merely to a weakened and dilated ventricle, eighty-five cases remained for treatment. These were divisible into two groups: 1st, those which on admission into hospital had a bruit, probably, but not certainly of recent origin. They numbered fifty-four; of these thirty-four left hospital with hearts apparently sound, while twenty were believed to have valvular disease. 2nd, those in which the bruit and other signs of valvular disease came on in hospital, or in which the onset had been recently observed by the practitioner who sent in the case. They numbered 31; of these 27 left hospital with an apparently sound heart, three with valvular disease and one remains under treatment. As far as possible the apparently cured cases have been kept under observation for months or years. One unsatisfactory point should be noted; if in a case apparently cured, rheumatism occur,

(a) Read before the Bradford Medico-Churgical Society, February 20th, 1900.

at an early date, the endocarditis generally recurs also, and, though sometimes it is again removed by treatment, more frequently it persists. The author gave a brief summary of 85 cases and read details of three. The author's experience of rheumatic endocarditis causes him to insist strongly on the two following principles. First, that every case of acute rheumatism should be regarded not merely and essentially as *rheumatism*, which is in itself comparatively unimportant, but, first and before everything else, as a case of *impending peril to the heart*, endangering the whole future life of the patient. Whenever the heart is sound at the outset the practitioner should examine it daily. Secondly, in all forms of acute endocarditis, there is a brief stage during which, if treatment is begun promptly, the disease is usually curable. In adults this stage probably only lasts two or three weeks; in children it is longer. In children, and to a less extent in adults, by persistent rest alone some cases recover. In the author's opinion the proportion of recoveries is larger if the three measures above described are adopted and persevered in for at least six weeks. The *bruit* usually becomes soft, and after being for a time variable, finally vanishes. After disappearance of the *bruit* and other symptoms, avoidance of all active exertion is desirable for at least two months further.

The PRESIDENT observed that there could be no difference of opinion as to the importance of perfect and prolonged rest. Some difference might possibly obtain in regard to the use of the iodides, and also in regard to blisters which, in young or nervous persons, might interfere with physiological rest. He did not think that any case of rheumatic endocarditis could be described as "unsuitable" for treatment on the lines laid down by the author. He insisted on the good results of careful and prolonged treatment of endocarditis, and upon the disastrous consequences of leaving endocarditis to take care of itself when the rheumatic disease had apparently subsided.

Dr. BURNEY YEO recalled that upwards of twenty years ago he had called attention to the value of the iodides during convalescence from rheumatic endocarditis ("Manual of Medical Treatment," page 308). Under its influence he has seen the physical signs disappear. Blistering over the præcordia was an old method of treatment. Dr. Harkin, of Belfast, was in the practice of putting a very large blister over the præcordia, and Dr. Whittia was loud in his praise of the effects. He remarked that much harm was done in these cases of rheumatic endocarditis by the routine use of digitalis, which certainly did not promote functional rest.

Dr. F. DE HAVILLAND HALL said that as one of the survivors of the præsalicylate days he was able to add his testimony to the value of blisters in the treatment of pericarditis as well as of endocarditis. He always began, in the case of hospital patients, by the administration of three grains of calomel with a grain of opium, repeating it from time to time if the bowels were constipated or if there was much pain. He referred to the frequency with which valvular disease in children was overlooked, and he urged that if more care were taken heart disease would probably be less frequently the result of the disease than was actually the case. The salicylate treatment had incontestably done a vast deal to lessen the misery of the disease, but he did not think it had materially lessened the stay in hospital; in fact, by relieving the pain so promptly it encouraged the patient in the desire to go out early. He commented on the short periods during which some of the author's patients had remained in hospital, in some instances only four weeks. He remarked that many patients who left the hospital apparently quite well afterwards developed signs of heart disease, so that a man who had had a recent attack of rheumatic fever, even if exempt from signs of valve lesions, could not be regarded as a good subject from a life assurance point of view. He mentioned that the late Dr. Sturges had described the condition of the heart in these cases as "pancarditis," which he thought well described the condition. He called attention to the anæmiating influence of the disease on the body generally, and said that during the last ten days or so of the patient's stay in hospital he always gave them

iron, arsenic, and, perhaps, strychnine. He agreed in deprecating the indiscriminate and too frequent use of digitalis in the early cases. In conclusion, he remarked that if iron were given too soon it tended to bring about a recrudescence of the arthritic pain.

Dr. MORISON recalled that sixty years ago the late Dr. Hope had laid down lines of treatment, except in regard to the salicylates, identical with those formulated by the author. The old physicians had a great horror of applying blisters in pyrexial conditions, but he added that personally he had never seen any inconvenience result from that practice. He then discussed the various explanations of the way in which blisters acted.

Dr. MACLAGAN remarked that rheumatism of the joints quickly subsided under treatment whereas rheumatism of the heart was very slowly recovered from, probably because it was easy to afford complete rest to the joints and much less easy to the heart. He attached primordial importance to rest as a factor of treatment, and with this and suitable medicinal treatment he thought that many cases would recover perfectly. Formerly when the disease ran a long pyrexial course the damage could not be recovered from, but under the salicylate treatment that no longer obtained. He observed that in acute rheumatism the heart was usually affected within the first week and he commented on some of the author's cases in which this competition was not noticed until the third week. He admitted that blisters afforded relief, but they were not applicable in the cases of children or nervous women. He pointed out that in regard to the heart that it was not the endocardium that was affected but the fibrous structure of the valves, and this gave rise to no physical signs, consequently it could not be recognised. It was not until nodules were thrown out that it became perceptible. It followed that the first stage passed unnoticed. He pointed out that the growth of these nodules could not be the result of friction but was the consequence of the inflammation of the fibrous elements of the valves.

A FELLOW observed that the practice of blistering the joints required to be carefully considered before arriving at any conclusion. The disease was possibly one of septic origin, and effusion into the joints removed much of the poison from the system, and its occurrence was associated with much relief to the pain. That blisters gave much relief to the joint pain they all knew, but whether they were good in regard to the general condition was another question.

Dr. POYNTON discussed the pathological aspects of the question, and mentioned that in a recent series of 24 cases of acute rheumatism admitted to hospital, two of them had endocarditis on admission, and of these two one went out well and all the others left well. He insisted on the changes that took place in the heart muscle in this connection, and he referred to the results of his examination of the heart muscle in six cases of acute rheumatism, in five of which there was marked fatty degeneration. In chronic cases he had found fibrotic changes spreading to the vessels, with foci of cellular infiltration between the muscle fibres. He pointed out that these changes could not be due to the valvular disease nor to pericardial inflammation. The fatty change was not due either to interference with the coronary circulation, in proof of which he instanced a case of syphilis of the heart causing almost complete obstruction of the coronary arteries in which no fatty change was found. He also mentioned other cases in which the changes were obviously of long standing. In a case of very acute chorea which proved fatal the valvular disease was slight, but there were numerous micro-organisms with pronounced fatty change. He suggested that just as the toxin of diphtheria acted directly on the heart so the poison of rheumatism had a direct effect on the heart muscle. In considering the treatment they must take into account not only the valvular disease, but this undoubted action of the disease itself.

Dr. EWART asked the author whether he opened the blisters? With regard to the action of iodide of potassium he pointed out that this drug did not, as was generally believed, tend to coagulate the blood, but, on the contrary, kept it fluid, and in a disease such as endo-

carditis, in which the lining membrane of the heart was diseased, he urged that this effect was likely to be beneficial.

Dr. DAVIES referred to a series of twenty-four cases published by his father in the "London Hospital Reports" for 1864, who all went out without any cardiac disease. His father's treatment was exclusively by blistering, and if he had to choose a treatment for himself he would prefer blistering to the salicylates.

Dr. LONGHURST protested against the adoption of any particular method of treatment for all cases urging that each case required to be considered by itself, the underlying constitutional condition—syphilitic, tuberculous, &c.—being borne in mind.

Dr. CHAPMAN suggested that the iodide acted by lessening the blood pressure, thus reducing the work to be done by the heart.

Dr. HALE WHITE observed that it was often very difficult to say when the valvular disease was recent or otherwise, and if the author's tables were looked at with this fact in mind the results would be seriously modified.

Dr. SEYMOUR TAYLOR agreed that great relief of pain was afforded by blisters, but he thought it was a very round-about way of getting at the endocardium to blister outside the chest. To be efficacious the blister ought to be applied at the back of the neck where the cords containing fibres for the heart came off. Rest was the most important element of any treatment intended to prevent endocardial deformities. Patients ought never to be allowed out of bed under six weeks, and then iodide of potassium might come in useful. He asked to which factor of his threefold treatment the author attached most importance. He insisted on the value of the salicylate treatment provided the drug were given in suitable doses.

Dr. A. GARROD thought that as a rule very little was done in hospital by way of treatment in recent cases of endocarditis, and he agreed that if it were possible to do anything it ought to be done. He concurred in the great value of rest for weeks and even months, and he held that a patient who had shown signs of endocarditis ought to be advised if possible to remain on one level for at least six months. He suggested that it would be very interesting if the author could give them parallel statistics of cases treated at the same hospital on different lines. He was not convinced that the author's results on the whole were better than those which would be obtained by rest alone carried out to the very end. So long as three factors were included in the treatment it was impossible to say to which of them the results were principally due. He pointed out that an attack of rheumatic fever did not end with the patient's leaving the hospital, for the patient was exposed to many relapses of the joint trouble, and probably the same held good of the endocardial lesion.

Dr. CATON, in reply, said that he gave as much salicylate as the patient could bear, fifteen to twenty grains every three or four hours, reducing the dose if necessary to ten grains every hour or two. He continued that treatment for a considerable time after the pain and fever had disappeared. He contrasted the course of an attack of rheumatic fever of to-day with that of pre-salicylate days. In the days before the introduction of the salicylates he used to treat many cases exclusively by blistering with better results than were obtained by the then prevalent alkaline treatment, and he believed that the proportion of cardiac disease was less. He observed that a blister ought never to be larger than a florin, and such blisters could be applied to women and children without inconvenience. He applied a small poultice afterwards, and the serum escaped. He used the same treatment for pericarditis, but he thought this lesion tended more to get well of itself. He admitted that in his earlier cases he was not impressed with the importance of rest as he was at present, so that some of the patients certainly left hospital earlier than they ought to have done. He pointed out that he did not apply the blister over the heart but over the upper left chest, over the region, in fact, where the cardiac nerves were given off. Rest alone, or even with the salicylates, had not given him good results.

HARVEIAN SOCIETY OF LONDON.

MEETING HELD THURSDAY, MARCH 1st, 1900.

Mr. W. H. LAMB, M.B., President, in the Chair.

Dr. RISIEN RUSSELL made a communication on the

CLINICAL EVIDENCE UPON WHICH WE RELY FOR THE LOCALISATION OF CEREBELLAR DISEASE,

and illustrated his subject by lantern slides. While dealing with the question from a clinical standpoint, frequent reference was made to the evidence derived from experimental physiology, and he showed how this is to be utilised in clinical work. In referring to the attitude which characterises a unilateral lesion of the cerebellum (inclination of the head to the affected side so that the ear and shoulder are approximated, and rotation so that the chin points to the opposite side) he said that this sign cannot be too implicitly relied on in clinical investigations, and quoted a case in which a tumour was situated in the opposite lateral lobe of the cerebellum to that indicated by the patient's attitude. Moreover, he has met with cases of cerebral tumour in which the same sign has been present, in one of which the growth was situated too far forward to allow of the possibility of direct pressure on the superior peduncle of the cerebellum. Rotation is so rarely met with clinically, and the direction of reeling is so inconstant that these phenomena are of little value in localisation; but ataxy of the limbs is commonly more marked on the affected side in unilateral lesions of the cerebellum. Motor paresis is sometimes met with in the limbs on the same side as the affection of the cerebellum, and is an indication of cerebellar insufficiency, for such theories as have been advanced to account for it by pressure on the pyramidal fibres cannot account for the fact that the phenomenon has resulted from softening of the cerebellum consequent on vascular occlusion. Convulsions do not belong to the symptomatology of cerebellar lesions, except as consequences of secondary disturbance of other parts of the central nervous system, unless Dr. Hughlings Jackson's view be accepted that peculiar tetanic-like seizures which occur in certain cases of tumour of the middle lobe are of cerebellar origin. Rigidity follows experimental ablation, but when present as a result of disease of the cerebellum usually indicates secondary interference with the pons, for with the cerebellum alone affected there is more likely to be hypotonia of the muscles. The state of the knee-jerks affords little aid in localisation, for while there may be increased activity on the affected side as after experimental ablation, there may, on the other hand, be diminution on the side, or there may be great variability, or both may be abolished. Valuable information as to the side affected is derived from evidence of implication of the fifth, seventh and eighth cranial nerves, and, in a few cases, from the twelfth; but even this evidence cannot be relied on as infallible.

Dr. LEONARD GUTHRIE cited cases illustrating the difficulty in localising cerebellar lesions, and even in deciding whether they existed at all. A boy, æt. 5½, had typical "cerebellar" gait, loss of knee-jerks, ataxy, and "intentional" tremors of upper extremities, left-sided facial paralysis, headache, and increasing drowsiness and languor for nearly three months. He then made a rapid recovery, and three years later remained in perfect health. Here symptoms of cerebellar disease were possibly due to polyneuritis. Another boy, æt. 7, had cerebellar gait leading to ataxia, weakness, and ataxy of right arm, loss of left knee-jerk and exaggeration of right, double optic neuritis, vomiting, and frequent headache, referred to the left frontal region. The symptoms pointed to right-sided cerebellar lesion, but a cyst of the middle lobe of the cerebellum was discovered. This case showed that the "crossed cerebellar" headache was not so valuable a localising sign as it had been held to be. A lad, æt. 18, now under observation, had "intention tremors," ataxy and weakness of right arm, slight spasticity of right leg, with exaggerated knee-jerk and ankle clonus, with normal plantar reflex, shambling, awkward gait, double

optic neuritis; but neither headache nor vomiting. The symptoms apart from the optic neuritis resembled those produced by destruction of the right cerebellar hemisphere, yet they were not conclusive evidence of such a lesion. Finally, he mentioned a case in which symptoms pointing strongly to tumour of the right cerebellum, proved to be due to tumour of the corpora quadrigemina.

Dr. H. A. CALEY remarked on the clinical importance in relation to localisation, of the association in some cases of unilateral paresis with a lesion of the cerebellar hemisphere on the same side. To overlook this point might lead to serious error in differentiating between cerebellar and cerebral lesions.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

A CLINICAL MEETING WAS HELD AT THE WEST LONDON HOSPITAL ON FRIDAY, MARCH 2ND.

Mr. L. A. BIDWELL, Vice-President, in the Chair.

Dr. CAMPBELL POPE showed a case of brachycardia in a child. The girl, *et.* 9, had had pleuritic effusion on the left side, following whooping-cough two years previously. She had also been run over and kicked in the head by a horse. The usual pulse rate was 33. Dr. Campbell Pope showed a man who had been operated on by Mr. Marmaduke Shield for abscess of the spleen.

The cases were discussed by Dr. Seymour Taylor, Mr. Rickard Lloyd, and the Vice-President. Dr. Campbell Pope briefly replied.

Dr. SEYMOUR TAYLOR showed a case of palsy of the sixth, seventh, and eighth cranial nerves.

Remarks were made by Dr. S. D. Clippingdale, Mr. G. Pernet, Dr. Campbell Pope, and Mr. R. Lake. Dr. Seymour Taylor replied.

Dr. PHINEAS ABRAHAM showed two cases of skin disease: (1) A case of pemphigus; (2) a case of dermatographia. The latter an extremely well marked instance of a rare affection. Some words which had been written on the skin of the chest in the afternoon were quite distinct at a late hour in the evening, and, indeed, still stood out prominently from the surrounding skin.

The Vice-President made some interesting remarks on the condition and Dr. Abraham replied.

Mr. H. J. PATERSON showed a case of psoriasis. There was great difficulty in the diagnosis between simple and syphilitic psoriasis. Although the eruption had the character of a syphilitic rash, and although it had not the appearance and distribution on which we relied in making a diagnosis of simple psoriasis, yet the general opinion was that the case was one of simple psoriasis.

Remarks were made by Dr. P. Abraham, Mr. G. Pernet, and Dr. T. H. Dickson.

The VICE-PRESIDENT showed two cases of pyloroplasty.

Dr. A. H. W. CLEWOW showed a case of excision of the pylorus; the operation had been performed by Mr. C. B. KEETLEY with excellent result.

Mr. MATTHEWS DUNCAN for Dr. F. G. D. DREWITT showed a case of aneurysm of the aorta in a woman, *et.* 41.

Mr. BASSANO showed a man suffering from great deformity of the chest on the left side, due to congenital absence of ribs.

BRADFORD MEDICO-CHIRURGICAL SOCIETY.

MEETING HELD TUESDAY, FEBRUARY 20TH, 1900.

The President, Mr. HORROCKS, in the Chair.

Dr. BRONNER showed a series of specimens, macroscopical and microscopical, illustrating growths of the nose.

Dr. CROWLEY showed specimens—(1) cancer of uterus, with secondary deposit in lungs; (2) a thrombus of the pulmonary artery firmly adherent and evidently of old standing; (3) perforating tuberculous ulcer of the small

intestine; (4) the brain of a microcephalic idiot. The child was three years old, weighed 14½ lbs., and the brain weighed 11 ozs.

Mr. ALTHORP showed specimen of a very extensive tumour of the thyroid gland occurring in a child seven years old. The patient had been apparently in good health till about three months before admission to hospital, when it was said to have developed whooping-cough, and soon after this the mother noticed an enlargement of the neck. The child was found after admission to suffer from attacks of severe inspiratory dyspnoea, which were at first relieved by medicine (belladonna), but this drug soon lost its effect, and failed to control its paroxysms. The thyroid body was seen to be greatly enlarged laterally, and the isthmus much thickened. The isthmus of the thyroid was exposed and divided between two ligatures. This gave great relief, and for a fortnight the child had no attack of dyspnoea. At the end of this time, however, it had another paroxysm, which proved fatal. On post-mortem examination there was found to be a large tumour of the thyroid body, which spread downwards into the mediastinum, completely surrounding the trachea and invading the wall on the right auricle. The growth was a lympho-sarcoma.

Dr. RABAGLIATI showed a portion of the ramus of the lower jaw, which had been removed by operation. The patient had a cystic swelling of the jaw which had been repeatedly tapped without relief and was supposed to be sarcomatous. The portion of the jaw was consequently removed.

Mr. HORROCKS showed a right tubal pregnancy of about six weeks' duration, which had ruptured into the broad ligament and was removed by abdominal section. It was taken from a woman, *et.* 35, who had had no child for twelve years, but during that time had two abortions. She had apparently a third abortion at the beginning of the present illness, and discharged a thick-walled cyst from the uterus. The discharge of blood continued for some time. On examination there was found a rounded swelling closely attached to the uterus, and this when removed was found to be the specimen shown.

Dr. METCALFE showed two sarcomatous tumours which had been removed from the popliteal region at the site of an old bullet wound. The patient had been wounded in battle eighteen years before. The wound healed, and nothing was noticed for nine years, when a swelling formed in the scar and was excised and said to be a fibroma. No further trouble was experienced till two years ago, when he twisted his lower limb violently and a good deal of blood was effused beneath the skin at the site of the old injury. This never cleared up and eventually the tumours shown developed and were removed by operation. They were found to be sarcomata on microscopic examination. One was solid, the other cystic.

Dr. T. JASON WOOD read notes of an unusual case of ovarian tumour which will be found under "Clinical Records."

Mr. J. BASIL HALL read a paper on gastrotomy, with an account of two cases, and made remarks on palliative operations in general, particularly colotomy. After reviewing the history of the operation of gastrotomy, the methods of performance as introduced by Albert and Witzel were described. The former being advocated when it was possible to bring the stomach readily to the surface, and the latter when the stomach was contracted. Mr. Hall strongly advocated the performance of gastrotomy in cases of malignant disease of the *œsophagus*, and urged that the operation be not delayed after the power of swallowing solid food was gone.

Drs. HORROCKS, ALTHORP, and WOOD made remarks.

Dr. LODGE advocated the use of resting tubes in *œsophageal* cancer.

Dr. HALL replied.

THE *Lancet* postcard *plébiscite* of medical practitioners on the subject of the Midwives Bill gives the proportion of five to one against it.

[FROM OUR OWN CORRESPONDENT.]

PARIS, March 10th, 1900.

OBESITY.

At the meeting of the Académie de Médecine, M. Deboue presented a man of fifty-five whom he had treated successfully for obesity. On entering the hospital the patient weighed 234 pounds; at present, that was to say after a year's treatment, he weighed only 180 pounds. The mother and brother of the man were also of large corpulence; he was consequently predisposed to his malady. It was at the age of twenty-five that he commenced to grow fat and that tendency was encouraged by the sedentary existence and the alcoholic habits of the patient. To that obesity were added two maladies which frequently accompanied it, gravel and gout. It was necessary to reduce his weight as he had become entirely impotent. What curative method should be employed? One of three. The first consisted in the administration of preparations of the thyroid gland; but that medication was dangerous, especially where it was necessary to be continued for a long time; besides, the results of it were purely temporary. For both of those reasons he did not wish to have recourse to it in treating the patient. The second method consisted in forcing the patient to take active exercise so as to provoke a waste of tissue, but the man could not leave his bed. The third method, that of insufficiently nourishing the patient so as to oblige him to consume his fat was the only one applicable to his condition.

During the first month of treatment he was put on two quarts of milk a day, the second one and a half, and the third month one quart only. He lost by this way 27 pounds the first two months, and four pounds the third month. During the four following months the patient took less than a quart of milk a day, and then only weighed 190 pounds, and, finally, his weight fell to 180 pounds, and he was now in perfect health.

RETRO-UTERINE HÆMATOCELE.

M. Regnier spoke on the treatment of retro-uterine hæmatocele at the Société de Chirurgie, and said that since 1890 he had operated 39 times successfully except in three cases. The method employed was laparotomy in 31 cases, six times for extra-uterine pregnancy from two to four months, and four times for inundation of the peritoneum. Of the cases in which he incised the cul-de-sac he had to practice once hysterectomy because the seat of the tumour was out of reach: the patient succumbed. In another case immediate laparotomy was rendered necessary from hæmorrhage. The speaker mentioned several similar cases communicated to him by his colleagues necessitating laparotomy, while one patient died from the hæmorrhage, which came on several days after the incision of the hæmatocele in the cul-de-sac. He consequently believed that laparotomy was justifiable in every case of voluminous hæmatocele, and of relatively recent date, while the small tumours should be reserved for the retro-uterine incision.

CACODYLATE OF SODA.

M. Vidal said that he had used cacodylate of soda in subcutaneous injections on several tuberculous patients, at the daily dose of from one to two grains. In the advanced stages of phthisis the treatment did not give much result. On the other hand, in the incipient stage

of the malady, the cacodylate of soda increased the appetite and the strength as well as the number of the red corpuscles with surprising rapidity. M. Hazem remarked that he had tried the cacodylate of soda in chlorotic patients, but the advantage was not very well marked, and he was always of the opinion that preparations of iron were the only specific for chlorosis.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, March 10th, 1900.

RHEUMATIC FRICTION SOUNDS.

WEINLECHNER exhibited a young woman to the "Gesellschaft der Aerzte" with peculiar sounds in both legs when an attempt was made to flex or extend them, although both were functionally disabled from a previous attack of articular rheumatism. The patellæ were normal and not displaced. A similar sound was present in the ring fingers when moved. He was unable to give any reason for this phenomenon, but thought he might commence treatment by applying a firm bandage in the extended position, with subsequent opening of the joint if found necessary.

TORSION OF THE OMENTUM.

Hochenegg followed with a specimen from a male patient, whom he also presented, æt. 41, on whom he had operated for presumable appendicitis. The history of the case excited much interest. It appears he was born as a cryptorchid, the right testicle appearing as an inguinal hernia which was afterwards kept back with a truss. In 1899 the hernia got strangulated, but was replaced with much difficulty by the taxis method.

The following day intense abdominal pain, vomiting, shivering, and tympanitis, with a temperature of 38 degs. Cent. (100.4 degs. Fahr.). In another day all the violent symptoms receded, but the general system began daily afterwards to decline. Both inguinal rings were examined but found to be free; and nothing externally could account for the declension. A little tenderness and swelling appeared later over Poupart's ligament which led to the conclusion of an inflammatory condition of the appendix on the right side.

On laparotomy being performed the transudation of blood from the whole surroundings was enormous; they were everywhere hypertrophied and œdematous, with here and there large thrombosis of the veins. On closer examination of this venous stasis it was discovered that the omentum had been three times turned on its own axis; this almost obliterated the return of the blood, and produced the morbid condition present. After removing the omentum, and closing the inguinal canals, the patient recovered without a bad symptom.

This, we think, is the first case of intra-abdominal torsion recorded in literature, although two others are reported as having occurred in a hernial sac.

CARDIAC VARIATION.

Heitler, according to announcement, gave the results of his laboratory experiments on the variable volume of the heart. He used a pericardial sac as a plethysmographic chamber.

The heart alters in volume when in a normal condition by simple blood pressure. The increase is sometimes on

the right, sometimes on the left, and often on both sides by the blood pressure alone.

Dilatation of the heart is caused by compression of the aorta, vena cava, or by irritation of the pericardium, the vagus nerve and accelerans, as well as subcutaneous injections of the ordinary salt infusion.

CARCINOMA OF SIGMOID FLEXURE.

Paltauf demonstrated, from a preparation of carcinoma taken from the sigmoid flexure of a twelve-year old boy, that the young are also subject to this disease. From 10,000 cases of carcinoma, however, he had only 19 cases to report under 20 years of age, which showed that such cases were rare.

TERATOMA—FŒTUS INCLUSUS.

He also showed a teratoma which he had removed from the back of a child, æt. 4½. This foetal growth was about the size of a child's head, covered with skin, and having distinct jaws, lips, and teeth, with hairy parts about 20 centimetres long; an alimentary and spinal column could also be traced. The connection with the midriff was not traced, but a foetus inclusus of this kind is very seldom met with.

INSPIRATORY PHENOMENA IN BRONCHO-STENOSIS.

At the Medical Club, Holzknecht related his experience with the Röntgen rays in broncho-stenosis. He brought this subject before the Society some time ago, and affirmed that the mediastinum was *always pressed towards the affected side*. The cause of the phenomenon, he avows, is due to the different balance of pressure in the two halves of the thorax. He showed a male patient, æt. 5½, who had suffered for a year and a half with difficulty of breathing and cough. Anteriorly and to the right, close to the sternum, pulsation could be both seen and felt; above this it was dull on percussion. The heart sounds were normal, except over this area of dulness, where the second sound was lost and a rushing substituted. With the Röntgen rays a shadowy mass was seen to the right of the vertebræ with indistinct pulsation. By a deep inspiration the whole mass was transported to the left side as well as the heart.

He also exhibited a female, æt. 35, who had all the symptoms of stenosis of the vena cava superior. Dulness was observed by Nothnagel anteriorly, and superiorly to the right with pleuritic effusion. The diagnosis was mediastinal tumour, which must be modified, as there was night sweating and fever with subsequent absorption, which is in favour of a tuberculous process which had compressed the vena cava. In deep inspirations all was pushed to the right side in this case also.

The Operating Theatres.

ST. THOMAS'S HOSPITAL.

INTESTINAL ANASTOMOSIS FOR CARCINOMA OF PYLORUS.

— Mr. W. ANDERSON operated on a patient, an emaciated and anæmic woman, æt. 40, who had been suffering from symptoms of dilatation of the stomach with progressive enfeeblement for nearly twelve months. During the past three months daily vomiting had occurred several hours after each meal, and it had recently become necessary to resort to rectal feeding. On examination of the abdomen a dilatation of the stomach was readily detected, but no distinct tumour could be felt; the bowels were acted upon regularly and without abnormality. Under the diagnosis of carcinoma of the pylorus it was deter-

mined to perform an abdominal section. A vertical incision was made slightly to the left of the median line above the umbilicus. On incising the peritoneum the dilated stomach was at once exposed; the hand introduced through the wound felt a large carcinomatous mass, as large as a fist, investing the pylorus. This was somewhat fixed, and although no glandular enlargement could be felt, it was judged that the patient's condition forbade the removal of so extensive a disease and it was determined to perform a gastro-jejunostomy. The first coil of the jejunum was drawn up to the level of the stomach and sutured to it by continuous Lembert's stitches; an incision of an inch-and-a-quarter in length, parallel to the long axis of the tube, was made, the lower borders of each were then sewn together by stitches passing through the whole of the coats, and the process was then continued to the upper borders, the needle passing through the whole of the coats from within outwards till the entire circumference was united, leaving an aperture of anastomosis between the two viscera. A few supplementary Lembert's sutures were then applied, and finally an outer circle of continuous Lembert was completed. After carefully cleansing the exposed surfaces, the intestine was returned, and the wound closed. The suturing occupied a period of less than half-an-hour, and the operation was well borne. Mr. Anderson said that it was very unfortunate that the admission of the patient had been so long delayed; had she come under treatment before, the whole of the disease might undoubtedly have been removed. As it was, the only resource was the establishment of an anastomosis between the stomach and the jejunum. He had hitherto found the method adopted safe and expeditious, and there was reason to hope that in spite of the patient's extreme prostration she would have a new lease of life, and a removal of the distressing symptoms from which she had hitherto suffered.

It is satisfactory to state that the next day the patient was bright and cheerful, and had suffered no shock from the operation.

GUY'S HOSPITAL.

LARGE CHRONIC ABSCESS COMMUNICATING WITH THE URACHUS.—Mr. ARBUTHNOT LANE operated on a child, æt. 2, who presented a sinus near the umbilicus leading by a funnel-shaped channel into a large, pear-shaped cavity extending into the true pelvis in front of the bladder, and running behind the symphysis. It was found on distending the cavity with milk through the sinus that there was apparently no passage into the bladder, but on distending the latter with similar fluid, some of the milk found its way into the abscess cavity and escaped through the umbilicus. The cavity was laid open from the umbilicus to the upper margin of the symphysis; its interior was found to present a granulating surface, which simulated very closely an inflamed mucous membrane. On again distending the bladder with milk, a small stream was seen to escape from a minute aperture in the upper limit of the viscus. The wall of the cavity was thoroughly scraped, and it was packed from the bottom with gauze. Mr. Lane said it was impossible owing to the softness of the parts to do anything towards closing the aperture of communication with the bladder. He remarked that the condition found was very extraordinary; personally he had never seen a similar case. It was, in his opinion, the result of an enormously dis-

tended urachus, but the peculiarity was, he thought, that it extended, not in the abdomen, but downwards in front of the bladder and behind the symphysis. He drew attention to the fact of the injected milk having passed from the bladder into the abscess cavity, but not from the abscess into the bladder, showing that the minute aperture in the upper wall of the bladder was valvular. The subsequent progress of the case was most satisfactory.

SEXUAL DELUSIONS.

THERE are few questions which have greater importance for the profession than one which has of late years been forced on its attention by recurring instances of grave and serious circumstances in which medical men find themselves placed through groundless charges made by women who have been suffering from some ailment of their sexual organs. Closer study of the influence which such ailments exert on the mental condition of the woman has more clearly revealed her irresponsibility in the commission of various acts, and in her attitudes, whether of a domestic or social character, to those with whom she is brought in contact. The time has gone by when the old obstinacy that characterised judicial utterances and legal opinions in refusing to acknowledge such irresponsibility resulted in many a cruel and unjust decision. Modern lawyers, with a wider insight into a subtle but no less powerful forces operating in states of disordered mentalisation, prompting to acts which, to the older and more superficial observers, were regarded as criminal and responsible, have come to view the narrow boundary line of "a knowledge of right and wrong" as one impossible to maintain in the present advance in psychological knowledge. Slowly the legal attitude has given way before the

mass of medical proof which has clearly established the irresponsibility for certain acts which are the direct or indirect outcome of mental instability. This change possibly has not altogether been achieved through the work of medical psychologists, but has followed from the better education of the public mind generally, through anthropological work carried out in various directions, which has demonstrated the influences of heredity, consanguinity, alcoholism, and disease in the nervous system in the causation of insanity and crime. True, it is often most difficult to draw the line which separates the borderland of mental from that of moral responsibility. And this we fear, for obvious reasons, must ever be so. To isolate and fix a morbid impulse which has as its resultant some vicious propensity or criminal act, so as to establish a causal relationship between the two, must often be impossible, so inscrutable to the keenest and most cultured observation are the train of phenomena and the correlated influences which, stage by stage, lead up to mental and moral obliquity. All we can do in the majority of instances is to search for some strong and palpable proof of periodical temporary or permanent states of aberration. It often happens that we are helped in our search by physical and physiological conditions which are or have been coincident with the detected alienation. Taking for example the question in which we are now more specially interested, namely, the correlation existing between certain physiological phases through which the woman passes at different periods and under certain circumstances in her life, and the mental effects of these as shown in her temperament, moral acts, vicious tendencies, eccentricities, and varying shades of mental instability, we have ample proofs of such correlation. In the address recently delivered before the British Gynaecological Society, and which appeared in our columns, there was ample verification of such a relationship. At puberty, during adolescence, in pregnancy and lactation, and at the climacteric, ovarian insanity of various types is frequently manifested, and such insanity is not necessarily associated with any discoverable disease in the sexual organs. It is the associated functional disturbance consequent upon either the appearance or disappearance, excess or suppression, of the catamenia. Such is the all-powerful influence on the woman generally of the process of ovulation. The ovary in its secretion, in its periodical discharge of that function, with all its reflex potentialities and nervous excitations, becomes for the time being an irresistible factor in the being of the woman. The ovary, rather than the uterus, "is the woman." As a consequence, we are not surprised to find that, with predisposing tendencies, associated physical affections have at these times corresponding psychical developments, and that these latter are frequently of a morbid nature. If this be so, when we can detect no morbid state of the genitalia, how much more are we likely to find abnormal ideas and beliefs attendant upon diseased

states of the sexual organs! Observation has so frequently shown this connection to exist, that psychologists now include in their classification of mental diseases such forms as those of "ovarian," "climacteric," "hysterical," "old maids" insanity, as well as that of pregnancy. Not that it can by any means be demonstrated that the morbid impulses have their origin in some pathological condition in any of the woman's sexual organs, indeed, frequently such evidence is entirely absent. Still, in disorders of menstruation, in various affections of the adnexa, accompanying uterine fibromata, in the pathological changes in the uterus occurring either post-partum or at the climacteric, we meet antecedent states preceding the appearance of the disordered mentalisation sufficiently often as to establish the correlation we have referred to. This is more convincingly shown by the cure of the mental state by operation; also we have to remember those cases of post-operative insanity in which melancholia and mania, with various delusions, illusions, and hallucinations, occur as a consequence of gynaecological operations, certainly in a greater proportion than we find after other operative procedures. With all these facts before us, it is surprising that we do not more frequently find both transient and persistent delusions arising out of the necessary treatment of the sexual organs of women by their medical advisers. Such patients are often already reduced by physical suffering and incidental, yet unavoidable, circumstances associated with these affections, to a condition, both physical and mental, in which any suggestion or pernicious influence will start a morbid train of ideas, soon fixing themselves in the mind of their victim as realities. The obstinacy and persistence of such ideas are brought into stronger relief by the fact that the sufferer may be perfectly sane in all her other ideas and actions. Not necessarily is she included in the class in which we might expect such manifestations. She may not come under any of the sub-divisions into which we rather loosely divide neurasthenia. She is not "erotic," "emotional," "hysterical," or "vicious." Though, of course, it is more generally among the latter types that we do find the evidences of sexual insanity. A ready prey to charlatans of all kinds, to hypnotisers, palmists, clairvoyants, *et hoc genus*, are all such. And there is hardly any conceivable impression that such rogues may not make on their plastic imaginations.

The moral to be drawn from these facts is, that every medical man, be his position what it may, has to be always on his guard when his professional duties bring him into contact with a woman suffering from any sexual disorder. He cannot be too careful in protecting himself when advising operations, in making examinations, or in conducting treatment. By having a nurse or some friend of the patient present, or at least in close proximity, by taking short notes of his opinion or treatment at the time, he will protect himself against grave and baseless charges. Notwithstanding all this care, however, there still remains, as in the case just now concluded, risks for which no possible forethought or precaution can provide, to which all medical men are subject.

In this last instance the sympathy of all his professional brethren has been extended freely and warmly to Dr. Peter Horrocks.

THE REPORT OF THE ANTI-PLAGUE INOCULATION COMMISSION.

THE Report of the Indian Commission appointed to inquire into the subject of protective inoculations against plague has been issued in a form that presents the findings of the Commissioners, subject to the possibility of a few minor alterations. The broad result is encouraging for the future of this particular branch of serum-therapy, although its failure to establish a series of definite scientific conclusions must come as a disappointment to the enthusiasts of preventive medicine. The difficulties of this task have been simply enormous, and the Report practically amounts to an admission on the part of Mr. Haffkine that he has failed to obtain sufficient data to place his prophylactic serum among the established truths of medicine. Happily there appears to be no doubt in the minds of the Commissioners as to the value of the inoculations when the matter is weighed in an empirical balance. Many of the difficulties have been due to the character of the native population, which is full of the sloth, superstition, and apathetic fatalism familiar among Oriental nations. Indeed, it says much for the tact exercised by Mr. Haffkine and his fellow-workers that they have induced so many natives to submit to the operation. The motives that led to acquiescence appear to have been of a mixed nature. In some instances the natives surrendered to the friendly pressure of their chiefs, but more often it appears that they desired to secure certain privileges extended to the inoculated, such as the right of travelling without restriction, and of early dismissal from the segregation camps set apart for persons who had been exposed to infection. Those who have any acquaintance with life in India will readily believe that the natives who submitted to the process were generally influenced neither by the fear of death nor by the belief in the curative or preventive efficacy of the serum. This complacent attitude on the part of the native population is encouraging, as the future success or otherwise of plague inoculation in India must clearly depend chiefly upon its continuance. From this point of view it is fortunate that the administration of the serum is not attended by any serious inconvenience. Mr. Haffkine injected a large dose beneath his own skin, and was not prevented thereby from attending to his official duties, although next day he experienced a good deal of pain about the region of the puncture. Mr. Haffkine appears to have worked in the face of great difficulties, and it speaks volumes for his energy and strength of character that he succeeded in producing large quantities of the prophylactic serum and in using it upon many thousands of natives. An initial fallacy in the observations lies in the fact that the serum has not been standardised. The Commissioners in one part of their report insist on the necessity for the accurate

standardisation of the fluid, as being essential to the best results, by way not only of the attainment of protection but also of its duration. They point out, moreover, that such accuracy would probably do away with the necessity that now and then arises under present conditions of employing two successive inoculations. It appears that the strength of the serum was ascertainable only by the extremely rough plan of testing the turbidity of the fluid by holding it up to the light. By this means the amount of the dose was determined, and in the case of weak solutions no less than 20 cubic centimetres were required to obtain the desired effect. The drawback of so large a dose will be apparent when we learn that the degree of local inflammation to a great extent depends upon the quantity of fluid injected. The turbidity, it may be well to remind the readers, is due to the dead bodies of the bacilli which are contained in the clear nutrient medium in which they have been cultivated. Mr. Haffkine appears to attribute different characters to these two constituents, inasmuch as he believes that one confers protection, while the other controls the severity of an existing attack. That view, however, does not seem to have been established, indeed the balance of probabilities apparently lies in the other direction and shows that the virtue rests in the turbid portion of the serum. The Commissioners have had to reject the returns from the majority of districts for various reasons, as for example the existence of errors in statistics serious enough to falsify conclusions; the fallacy of attacks and deaths due to invasion contracted shortly before and after inoculation; variations in local virulency of plague; and the want of uniformity in the serum employed in different places. Notwithstanding doubts and difficulties of this kind, however, the Commissioners have been able to endorse the value of protective inoculation in broad and general terms. Their position has been ably summed up in the *Times*, which has all along taken an advanced scientific position with regard to this important question, in the following passage: "There is good reason to believe that, whenever inoculation has been extensively performed, the inoculated persons have yielded a smaller proportion of cases of plague, and the cases a smaller proportion of deaths, than were furnished by like numbers among those who were not inoculated; but the statistics do not appear to have been kept upon any uniform plan, nor have the conclusions based upon the figures been such as would always commend them to actuaries." Upon the whole, this Report appears to afford hope of solid future achievement in a field where the progress of preventive measures is surrounded by most formidable obstacles.

ANTI-VIVISECTION.

THE Society of Friends has issued to the medical profession an address on this well-worn subject which we feel is entitled to respectful notice, not only because of the benevolent and thoughtful source from which it emanates, but because of the modera-

tion of the language which it uses, and which contrasts very favourably with the hysterical vapourings of the average anti-vivisectionist. Nevertheless we apprehend that the Friends do not expect any number of our profession to agree with their line of argument, and we certainly do not. The advocacy of anti-vivisectionism is built upon the following statement:—"Members of the profession tell us that vivisection has added to our knowledge, and given some relief to human suffering. . . . We cannot believe that it is right that weaker creatures should be deliberately tortured by man, however beneficial to him the end in view." As regards the first of these propositions, we say that we positively decline to discuss the question whether "vivisection has added to our knowledge, and given some relief to human suffering." We must take that for granted, inasmuch as, in the world of scientists and the medical profession, not more than a dozen (including Mr. Lawson Tait and Dr. Berdoe), have ever dissented from it and, indeed, we should regard any third year's student as very ignorant of his business if he was unable to produce irrefutable evidence of its truth. Therefore, assuming it to be true, we may discuss the question whether "weaker creatures should be deliberately tortured by man, however beneficial to him the end in view." The Friends' Society say that the "more or less forcible suppression of his natural feelings of compassion, and of chivalrous tenderness towards creatures weaker than himself," would be a "ruinous price to pay for knowledge." Needless to say that we by no means concur in such a statement, for we hold that the gain which has accrued to humanity by vivisectional experiment would be amply sufficient atonement for pain inflicted on hundreds of guinea-pigs and rabbits, though, be it noted, we are perfectly aware that a large proportion of these experiments are conducted without any suffering whatever. The Friends' Society seeks to impress its humanitarian sentiments upon our profession because ours "is the high privilege of labouring, often with much self-sacrifice, to preserve the physical life of our fellow-creatures." Does it not occur to the Society that it would be wicked for scientists to abstain from using the most trusted means to preserve the life and alleviate the miseries of the human race because of the pain inflicted on a guinea-pig or a score of guinea-pigs? We should venture to suggest that human beings should certainly come first when torture has to be alleviated or life preserved, and we submit that, in seeking to prevent the pain necessarily inflicted by vivisection of the lower animals the Antis. are trying to increase greatly that which the human race would suffer from disease if it were not permitted to overcome such disease by vivisectional experiment, not to speak of the material loss which would accrue to the community from the premature disablement or death of useful earners. For our own profession we must challenge emphatically the suggestion that it is necessary for a surgeon to "forcibly repress his natural feelings of

compassion and of chivalrous tenderness towards creatures weaker than himself" when he is compelled to inflict pain on a patient. To say that he does so is an unmerited libel on him which it is not necessary that we should refute.

Notes on Current Topics.

Exoneration in the Divorce Court.

THE sensational divorce case that last week claimed the attention of a special jury ended in a way that is both satisfactory and unsatisfactory. The co-respondent, Dr. Peter Horrocks, the well-known assistant obstetric physician of Guy's Hospital, was dismissed from the suit, on the finding of the jury that he had not committed adultery. In the case of the respondent, however, they could not agree as to whether she had or had not committed adultery. The suit was brought by the husband, a medical man, upon the written confession of the wife to the effect that the father of her child was Dr. Horrocks, who had attended her professionally. Later, she withdrew that statement, which she declared to have been made while she was labouring under a delusion. Dr. Horrocks denied the charge against him upon oath. The case illustrates one of the peculiar dangers that place the reputation of a medical man at the mercy of a woman of weak mind. In this case the conduct of the respondent suggests mental disturbance of such a degree as to raise the question of how far she should be allowed out of systematic control in the future. One aspect of the case deserves comment, namely, the attitude of the legal advisers of the gentleman who brought the suit. It must have been perfectly well known to them that the wife withdrew her incriminating statement, and that the co-respondent denied the charge *in toto*. The absurdity of allowing a case of the kind to become public property is evident, for the veriest tyro in legal matters could have predicted the result of a retracted and uncorroborated confession. It is not easy to understand how responsible legal advisers can be found to conduct such a case.

The Exemption of Hospitals from Rates.

WE congratulate the President of the Local Government Board on not having committed himself to anything more definite than an expression of sympathy in replying to the delegates who had approached him for the purpose of urging the importance of legislation for exempting hospitals and infirmaries from the payment of local rates. We are by no means opposed in principle to the maintenance, or partial maintenance, of hospitals by municipal subventions, but from every point of view it is desirable that such financial assistance should take the form of direct contribution to the funds, thus leaving the matter within the control of the ratepayers. We are fully aware that precedents for such exemption abound, we would it were otherwise, but an evil is not minimised by extending its scope, and we heartily deprecate any further departures in this direction. If

this process is allowed to go on unchecked our hospitals will gradually merge into poor-law infirmaries, and the latter will consequently become supererogatory, but in the meantime the expense of running, two or more or less parallel sets of institutions will be greatly increased. In the large cities especially the system would press very heavily on the local ratepayer, who would thus be constrained to contribute to the medical care of large numbers of provincials who come to the large general hospitals in order to get the best possible advice and treatment. No, if the voluntary contribution hospital system cannot be kept going, let us frankly admit the fact and call upon the public to approve the principle of rate-subvention, and we see no valid reason why this should not take the form of a special rate. By the time this comes to pass it is to be hoped that the medical profession will be sufficiently organised to be in a position to protect itself against further abuse of medical charity on a scale previously unknown.

Compulsory Notification.

THE first prosecution in Ireland of a practitioner under the Notification Acts, as far as we can recollect, took place last week in Bray, co. Dublin, when the sanitary authority sued a local practitioner for having neglected to notify a case of diphtheria. He had attended the patient for what he described as a bad sore throat, and at the time he had informed the sanitary sub-officer that, in his opinion, the ailment was nothing more than this. According to his own testimony he was confirmed in that view, because the child got apparently well, and it was not until sixteen days afterwards that paralysis supervened which led him to believe that the disease might originally have been diphtheria. The patient died, and the cause of death was entered on the death certificate by the practitioner as "diphtheria (?)." The prosecution against the doctor was dismissed, the presiding Magistrate saying that it "was unfortunate that the doctor did not notify when he came to the conclusion that it *might be* diphtheria, but, as a doubt existed, the case would be dismissed." This case forcibly illustrates the hopeless weakness of notification law. The practitioner is in fact bound to notify when he "becomes aware" that the disease is infectious, and he is neither bound nor justified in doing so on mere suspicion. If he does so he may be mulcted in heavy damages, as Dr. Hadden, of Rathmines, was, for notifying a case which turned out not to be infective. Supposing that the practitioner desired to conceal the nature of the disease, which often occurs, no one could prove the case against him because no one but himself could testify as to the symptoms, and, if it were a mistake in diagnosis no prosecution could be sustained against any man for want of diagnostic skill. In fact, the compulsory notification law is ridiculous. It may be of use because it inculcates with authority a useful precautionary proceeding, but it can very rarely be enforced against the practitioner, and, in fact, has never been so enforced in even a dozen cases throughout the kingdom.

The American Cyanide of Mercury Case.

A STORY which, if not true, is, at least, well concocted, is told by the *Herald*, with reference to the recent conviction of a society man for poisoning a lady by sending her a bottle of bromo-seltzer dosed with cyanide of mercury. It is stated that Professor Walter Scheele, a chemical expert, having noted in a German book that cyanide of mercury is decomposed by free carbonic acid, such as exists largely in bromo-seltzer and is thereafter not hurtful, tried the experiment, and found that the statement is true and that, in presence of the carbonic acid, the hydrocyanic acid at once escapes. He, thereupon, went to the *Herald*, and offered to test the accuracy of the experiment on himself, but the authorities of the journal declined the responsibility. They, however, suggested that the Professor might try it on guinea-pigs in their presence, which he consented to do. When the occasion came, a guinea-pig was injected with the cyanide, and, of course, immediately died. Then a mixture of that drug with the bromo-seltzer was prepared, and the Professor prepared to inject. To the horror of those present he forthwith drank the entire mixture, and then prepared a mixture of tinct. ferri. perchlorid, which he enjoined them to administer to him in case he should appear to be sick, as it is a perfect antidote to the cyanide. Professor and guinea-pigs are reported perfectly well.

Cancer and Meat Diet.

THE late Mr. Charles Moore, surgeon to the Middlesex Hospital was, we believe, the first to draw attention to meat diet being a probable cause of cancer. The subject, of course, has often been referred to since then, that is to say, since 1865, when Mr. Moore first discussed it, and the opinion has for many years prevailed among those who have paid attention to the subject of cancer that the meat eating propensities of our race were in a measure responsible for our high death-rate from malignant disease. Within the past week Sir Mitchell Banks discussed this matter in his Lettsomian Lecture before the Medical Society of London, in which he expresses himself as being quite in accord with this view. Two facts in this connection must be admitted, first that cancer is increasing and secondly that an increased consumption of animal food among all classes has taken place during past years. The augmenting death-rate from cancer, although disputed by some, is nevertheless generally admitted to be proved by the figures in the Registrar-General's returns, while common observation shows that from the lower classes upwards, owing to general prosperity, animal food is more largely consumed than was the case in previous times. Sir Mitchell Banks thinks that the better classes eat infinitely too much now-a-days, but in this regard it should not be overlooked that there is a counteracting influence in the amount of physical exercise, and out-of-door pursuits to which resort is made. Again with regard to the lower classes the author believes that workmen fare admirably, and yet we should remember that quite possibly the

cancer producing effect caused by improved habits of living is considerably modified by their arduous occupations, and that the real result of their increased consumption of animal food is that of keeping them in better health, and rendering them less liable to seek the aid of hospitals. However, there is one aspect of this question about which no room for dispute exists, and that is for persons, both men and women who lead sedentary lives the present custom of high living is absolutely harmful and inexpedient from a health point of view. Medical men nowadays frequently come across patients who are obviously overfeeding themselves. Such overfeeding may be merely the result of an acquired bad habit, but unfortunately the ill-effects of the latter have generally become manifest before advice is sought. However, after the lapse of a few more decades the good influence of the exercise fostered by the use of the bicycle should begin to display its presence in an increase of the nation's health; possibly we may have in this the solution of the problem of how to reduce the mortality from cancer.

The Psychology of Courage.

COURAGE is not so much an absolute as a relative quality, and as it is made up of several physical factors it necessarily varies greatly according to circumstances. It is well known that the condition of the stomach, whether full or empty, has a great influence on the psychical condition of the individual in this respect, but *ceteris paribus* the excitability of the vaso-motor system appears to be the prime factor in bringing about the state of mind which we call courage. If the reaction to stimulus be prompt and sustained the central nervous system receives an adequate supply of blood to enable it to cope with the emergency, and an acceleration of the heart beat is therefore the first indication of such reaction. Failing this enhanced circulation the feeling of inadequacy is translated by mental distress, palpitation, trembling of the limbs, and, in severe cases, relaxation of the sphincters. In the average individual it takes a variable length of time for equilibrium to be re-established after receipt of the initial stimulus, and until it has come about, no decided action can be taken. The courage which comes gradually in the course of a few seconds or minutes is often more enduring and trustworthy than the *elan* which subsides as the magnitude of the danger dawns upon the consciousness. Curiously enough courage is not incompatible with a certain, and even marked, degree of nervousness or, shall we say, apprehension. No man in presence of imminent and obvious danger, unless he possess the power of temporarily inhibiting thought altogether, can help experiencing apprehension, but if his vaso-motor system is in good trim he may still command sufficient will power to constrain the recalcitrant flesh to do that which it instinctively abhors. The highest form of courage after all is that called for on the part of commanding officers under the influence of some unforeseen catastrophe. Under these trying circumstances temporary mental paralysis may ensue, and this is the

simple explanation of many a military failure, more or less catastrophic.

Gunshot Wounds with Mauser Bullets.

FROM the accounts published of the wounds inflicted on our troops by the Mauser bullets it may be inferred that it is, so to speak, a humane bullet, usually occasioning but little pain or hæmorrhage in traversing the body and limbs of the soldier. This may be adduced in its favour in contrast with the vastly more destructive effects of the old spherical bullet of bygone wars, or the big Snider bullet of more recent times. The special features of the Mauser bullet wound probably owe their character to its greater velocity and smaller diameter than the older projectiles, with, consequently, less strain upon the tissues through which it passes. There may be a modulus of elasticity inherent in the human tissues which is exceeded by the passage through them of the more slowly moving and more bulky old round bullet, which causes them to give way and be torn and disrupted from their connections beyond the immediate track of the projectile. This collateral action would give rise to extreme pain and cause laceration of blood vessels and nerves beyond those actually cut by the foreign body in its track. On the other hand, the swifter, less bulky, and more pointed bullet would probably glide through the tissues under the modulus of their inherent elasticity, thus leaving them in a condition to close again after the passage of the projectile, and so sealing up the track from bleeding. This unimpaired elasticity would allow the nerves and blood vessels to resume their normal positions without being torn or over-stretched, and would account for the diminution of pain and hæmorrhage following upon wounds by the Mauser and similar gunshot missiles. The aseptic character of these rifle wounds may possibly be explained by there being less air and *debris* driven in front of the pointed and narrower bullet. Waves of air are seen in instantaneous photographs to precede the missile like a buffer, and the wave of air following the base of the ball would in great part be shut off by the sphincter action of the elasticity of the penetrated tissues. Under the above circumstances grave shock to the system would be minimised in consequence of the lightning-like transit of the bullet through the body, provided it does not endanger the integrity of nerves or blood vessels.

The Housing of the Working Classes.

FROM the Annual Report of the Medical Officer of Health for Bath we learn that the problem of housing the working classes has received careful consideration in that ancient city. Bath is not by any means overcrowded, and the central parishes, where the poor chiefly live, are far less congested than they were seventy years ago. Many of the tenement houses were at one time the dwellings of aristocrats, and have thick walls, wide passages, and lofty rooms, while most of the streets are well open to light and air. Bath has its slums, however, and
